The garden forms of Cineraria are now almost endless, many of them showing a marked divergence from the cinerarias of a generation or two ago. Among the newer forms there is a great tendency towards the production of a lighter and more graceful class than formerly existed. The Star Cinerarias, often referred to as C. stellata, are by no means the only ones of this section. Among the Star kinds there is a much greater variety in colour than was at one time the case, and for general decorative purposes they increase in favour year by year. The class known as Feltham Beauty is remarkable for the light and elegant disposition of its flower heads, each one standing almost, if not quite, clear of its neighbour. The plants are of comparatively dwarf habit, and many distinct shades of colour occur amongst them. There is also a cactus section, in which the florets are rolled back at the edges, thus giving the blooms a very singular appearance. In colours, too, we have such marked departures, as the velvety-red Matador, the curiously-striped Pompadour, and the first steps towards a yellow-flowered variety. At present the distinct shade of Matador is to be found only in dwarf, dense growing plants, but we shall no doubt in time find it associated with the lighter and more elegant forms. W. T.

ROSES IN POTS.

All the pot roses should now be in full healthy growth, except it be a few kept back as far as possible to maintain the supply in the event of later flowers than usual from the wall plants in the open. Being in full growth, they will naturally need careful and constant attention. This is more particularly the case when a second crop of blooms is looked for from a few of our best and freest flowerers, not numbered among the climbing sections.

Such constant flowering hybrids and true teas as Sunset, Sunburst, Madame Abel Chatenay, Liberty, Richmond, Niphetos, Bridesmaid, Mrs. Aaron Ward, Catherine Mermet, Sunrise, and others most often found in the market at this season, will need considerable care to produce their second crop to the best advantage. If the flowers have not been used for decorations, they should be cut back as soon as over, paying due regard to the retention of the most promising and best situated young growths, that are generally to be found pushing out below. To leave the whole of these growths often results in a mass of wood, much of which is so overcrowded that only a small number of bloom buds can form. Even these cannot do themselves full justice under such crowded conditions, and judicious thinning is rather more necessary here than in the open.

As the younger growth advances, not a little benefit arises from the judicious removal of some older leaves that may be past their prime; but I would not overdo this, simply cutting away what would probably have been sufficiently matured to fall off through weather influences had the plant been growing in the open. We want to encourage as much air and light as possible to aid these younger growths to develop their flowers, and, simple as this removal of old and worn-out leaves may appear, I have had reason to think it did good.

When our roses are in this stage it is also a great help if some form of top-dressing can be afforded. Both Clay's and Thomson's manures have proved good here, and, not being so forcing as some, are ready for assimilation at the very time when most needed by the prospective flowers.

The question of cleanliness should really not need mentioning, for surely we all have experienced the absolute necessity of this if a good crop of any quality is to be secured. I am merely reminding readers once more of the great efficacy found in a steady and persistent use of some well-tried wash at a safe strength. A headlong rush to annihilate the enemy is seldom satisfactory, nor can there be any need for extreme measures if we but commence early and safely. Personally I do not regard this frequent use of the syringe upon all suitable occasions as directed solely against insect enemies. For from it. Quite a lot of good is done by the mere cleansing of the foliage. The leaves become dusty under glass, with no natural rains or movements of the air to remove the dust and dirt, as in the open. We cannot fail to note the freshness imparted by a genial summer shower, and if we can imitate this as far as possible inside, with just a little of some solution that insects dislike, we have a fine preventive against them and such insidious diseases as mildew.

We cannot give too much care and consideration to the application of liquid manures to pot roses. What would have room to spread and percolate in the open ground will not always be a safe strength for pot roses where the whole must necessarily come into direct contact with the

roots. It is far safer to use the manure weak and often, than strong and at intervals.

The question of shade is important. Roses enjoy ample light, but a clear sun shining through clean glass is often very fierce and scorching. Much of this will depend upon the aspect of the house. If built north to south the bars will form a considerable break to the sun's burning influence at midday and thereabouts. But if the building is more or less the other way—running east to west—the mid-day sun has no check, and consequently some artificial shading is often necessary quite early in the summer. The lighter this can be, with efficiency, the better. Damping down among the plants, with a careful avoidance of wetting the foliage, helps against the temporary distress of a more than usually bright day, such as we often experience during late spring.

I would not try for a third crop of flowers under glass. It seems too exhausting, and seldom allows the plants sufficient time to recuperate for next season's forcing. By the time the second crop is realised, too, the weather will allow of the pot plants having a steady rest outside. The old idea of forcing ripeness by withholding the water supply, even to the point of shrivelling the wood, does not find much favour now. For one thing, we have a different character of growth to deal with than was the case with the old hybrid perpetuals, which generally ripened off during the later summer months even when not exhausted by being forced. On the contrary, the present-day hybrid teas continue to grow and flower just as long as frost will permit them. Standing the plants upon a firm base, half plunging the pots where possible, and keeping them rather dry, is certainly conducive to a better maturation of the more valuable lower eyes we should cut back to when pruning once more. A sunny and fairly open position assists the ripening more than the older method of putting the plants upon the north or shady side of walls and hedges.

ROSARIAN.

Humea elegans.—For supplying plants for flowering next year a sowing should made now. Sow the seeds in pans in a compost of loam, leaf-soil, and sand. The soil must be passed through a fine sieve, and the seeds be only lightly covered. Place a sheet of glass over the pan, and shade from bright sunshine until the seeds have germinated. Afterwards keep the seedlings growing steadily in a greenhouse temperature. Keep the old plants in a cool house, and shade them during the hottest part of the day.—E, HARRIS.

Raspberries.—Assuming that the old canes were cut out soon after they ceased bearing, and the young, sturdy growth carefully secured to the trellises, the only work necessary at the present time is shortening the tips to the required height, cleaning the beds, and mulching if necessary. Raspberries require plenty of feeding to keep them in a fruitful condition, and especially when growing on light, porous soil. New beds may now be made; the land should be well trenched, adding plenty of thoroughly decomposed manure as the work proceeds. Plant in lines 6ft. apart, and set the young canes about 9in. apart in the rows. See that the roots are not buried too deeply. Work plenty of fine soil among the fibres, and tread moderately firm. As soon as the fresh growth appears, cut the canes down to within a few inches of the ground-level, and encourage strong growth for the next season's crop. Raspberries intended to fruit in autumn should be cut down without delay; with this treatment very good crops are sometimes produced late in the season. Our most dependable variety here is Superlative.—H. MARKHAM, Wrotham Park Gardens.

ARENARIAS.

The Sandwort family consists of dwarf creeping plants, many of very weedy habit and small flowers. There are a few kinds, however, that are extremely useful and ornamental for ledges and pockets in the rock garden.

One of the prettiest members of the genus is the Majorca sandwort (A. balearica), a moss-like plant, which forms a dense green carpet, studded in summer with small white flowers, and forming a sheet of white. Although it is a native of the warm islands in the Mediterranean—Sardinia, Corsica, and the Balearic Islands—it is quite at home in this country, surviving our winters without any trouble. It will grow almost anywhere, but it is the most happily placed when climbing over moist, half-shady rocks, its trailing stems clinging to the stones. While it will thrive either in sun or shade, the latter must not be too dense, or it will fail to flower freely. A northern aspect, with full exposure to light, will suit it admirably. The vivid green carpet that it makes is very attractive clothing the faces of the rocks, and then, in the spring, the star-like flowers commence to appear, gradually becoming thicker as the season advances. This plant is also useful as a carpet for such small bulbs as the bulbous irises, scillas, narcissi, such as N. minimus and N. cyclamineus, and others that require, or look better with, such a groundwork.

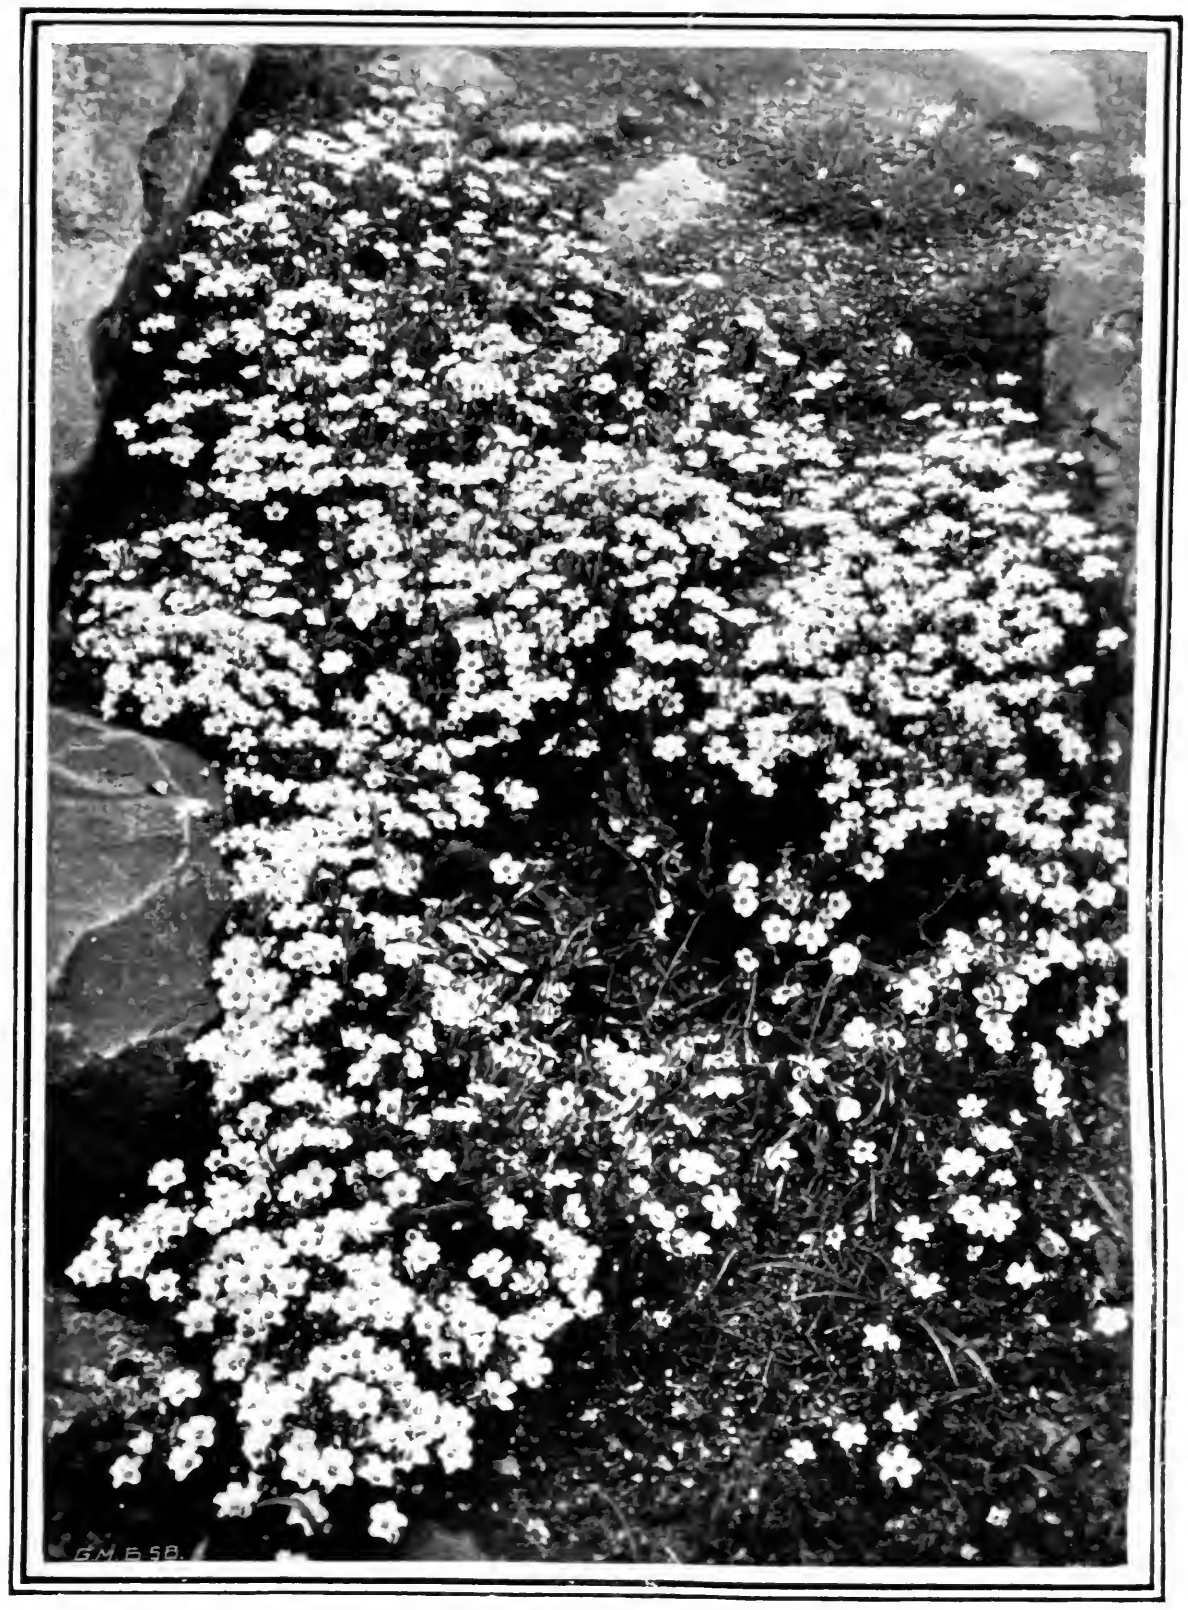
One of the best is A. montana, which is shown in the accompanying illustration. The mountain sandwort is unquestionably one of the most charming of the earlier-flowering kinds. It is a prostrate, spreading plant, equally at home as a carpeter on flat ground, or hanging over ledges in the rock garden. As a subject for wall gardening it cannot be surpassed, forming a draping carpet or curtain of large pure white flowers. It is an old garden favourite, having been in cultivation for over 300 years. Two forms of this are met with; one called grandiflorum, being of compact habit, and having rather more hairy leaves than the type, but the flowers are no larger.

A. purpurascens, a native of the Pyrenees, and, like most of the other kinds, of prostrate, spreading habit, is an interesting, if not showy, plant. The purplish-coloured flowers are freely produced throughout the summer, and it is a useful plant for the rock garden.

There are several other sandworts in cultivation, amongst these being the following: A. verna, which makes tufts of deep green foliage, covered with white flowers. A. v. cæspitosa is a valuable carpeting plant. One of the most distinct is A. tetraquetra, with the leaves set in four rows on the stems. It makes a compact tuft, but the flowers are of a dull white.

The cultivation of the various arenarias is very easy, as they are all readily propagated by means of cuttings in summer, or by seeds, which most of the species produce freely.

W. IRVING.



A FINE SPECIMEN OF THE MOUNTAIN SANDWORT (ARENARIA MONTANA).

TEN-WEEK AND OTHER STOCKS.

The garden stocks occupy a foremost position among the most select of our garden flowers. They have originated from a few wild kinds, of which Matthiola annua, M. incana, and M. sinuata are the most important, and from thes have been derived the Ten-week, Brompton, and Intermediate sections.

Ten-week Stocks.

The earliest type to flower in the open is the Ten-week, which is represented by dwarf, intermediate, and tall kinds, with numerous shades of colour, of which violet, mauve, lilac, blue, white, crimson, rose, pink, and pale yellow art the most distinct. The dwarf kinds rarely exceed a foot in height and are chiefly useful for low, flat beds of a formal character, or as edgings to taller plants, as their compact habit and uniform height give them rather a stiff effect, and places some restriction on their general use. Those of intermediate height have greater freedom, as the central spike is usually about 18 inches high, and with the lateral branches will cover an equal width when well grown. The Giant Perfection is the tallest of the Ten-week type. In this the central spike reaches a height of two feet, with numerous laterals of equally massive proportions. It is the best type for large beds, or for supplying cut flowers. In beds wholly set apart for a display of stocks the latter form should occupy the centre, and if the intermediate type is arranged in front, with the dwarf forms as a margin, an ideal arrangement, as regards height, will result.

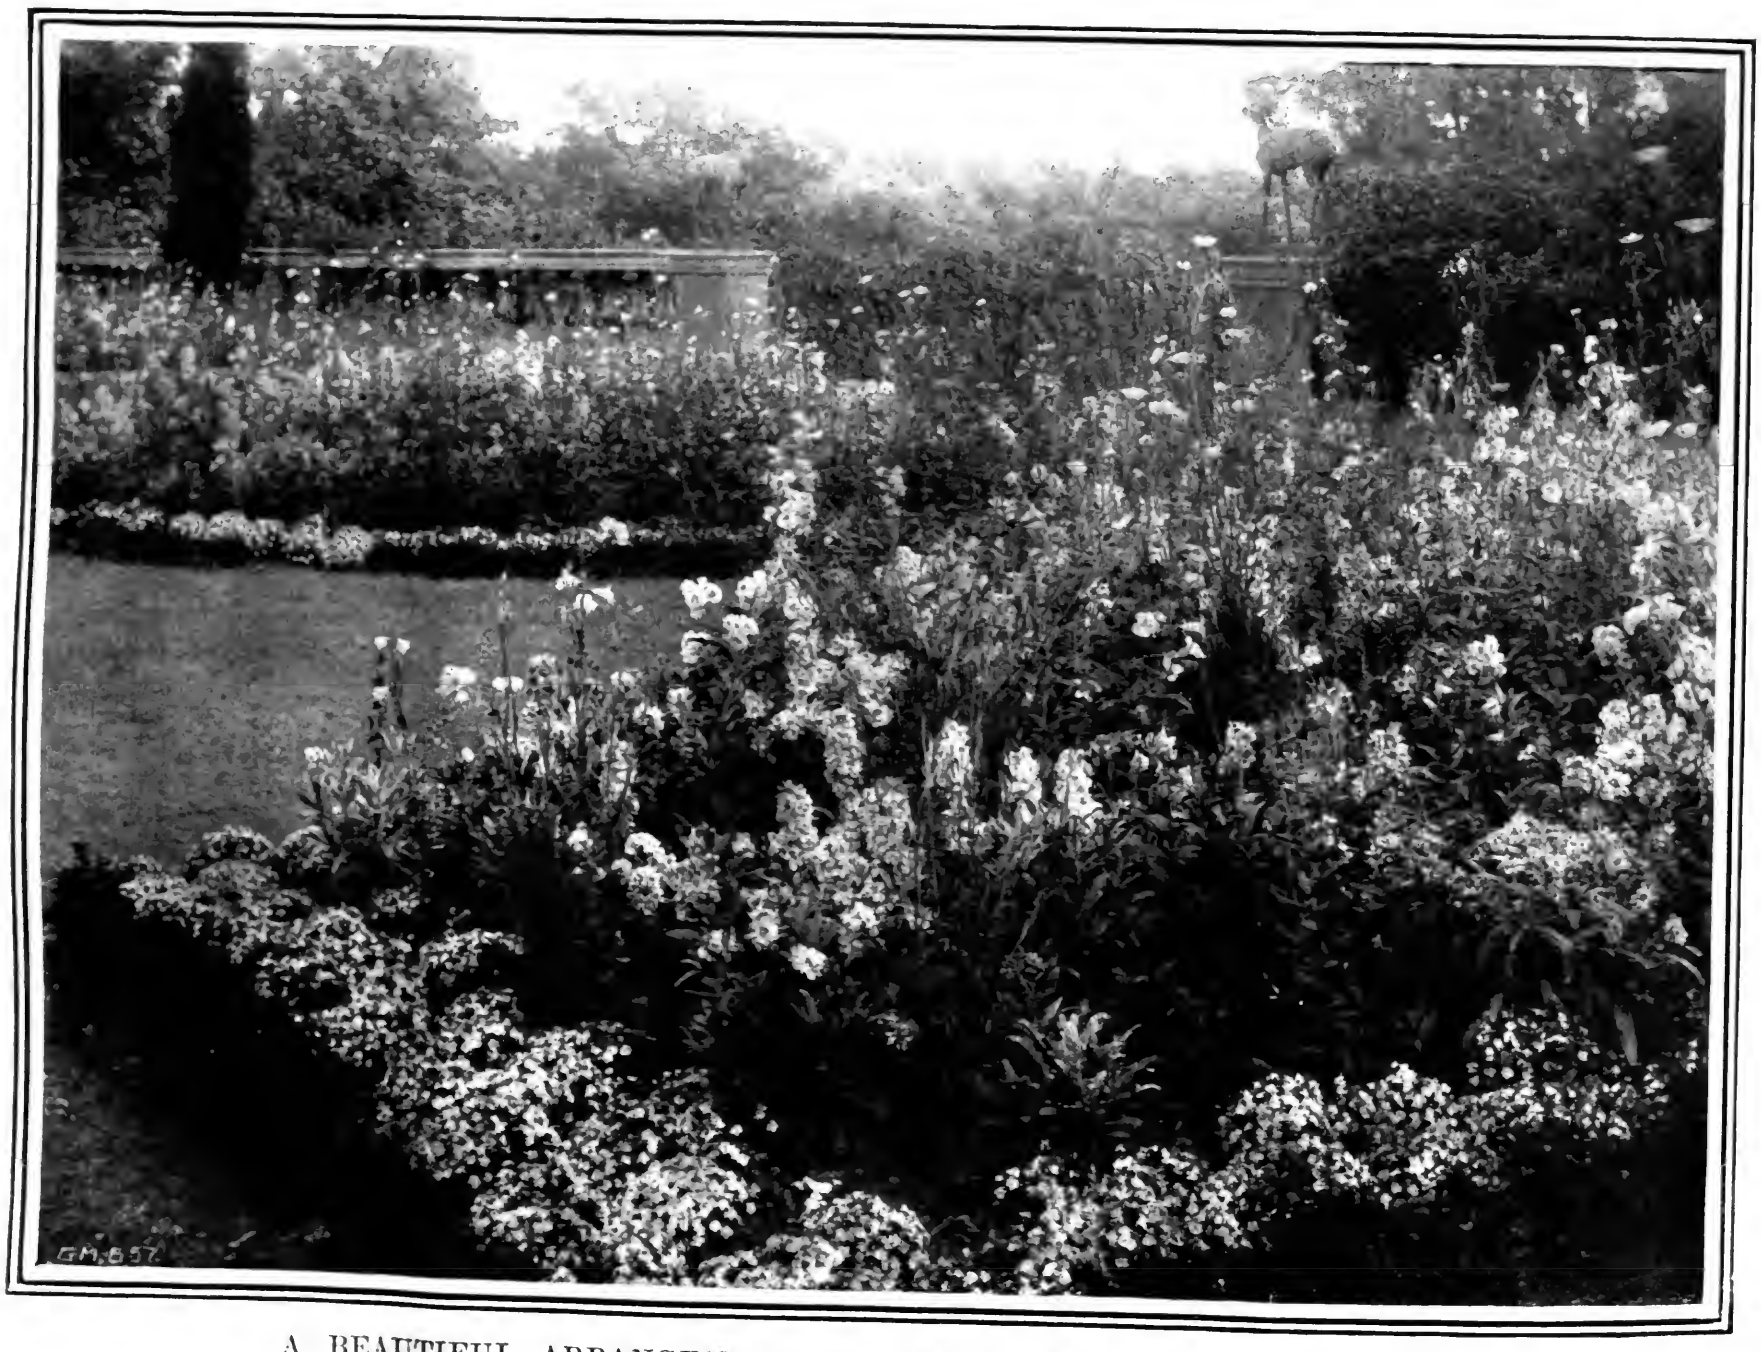
Ten-week stocks sown under glass in the first fortnight of March will furnish plants to flower in the open during June and July. The seeds germinate readily with sun heat, and as soon as the seedlings appear the pans or boxes should be given a position close to the glass, admitting abundance of air, so that hard-grown, stocky plants may result. When the seedlings are large enough to handle, they are best transplanted into boxes of rougher soil, and again into unheated frames, protected by lights, finally planting them in their permanent positions during May. Frequent transplanting induces a much-branched root system to develop, which is of great benefit when the final planting out takes place. A succession to the earlier batch is made by sowing again in unheated frames in April, and these seedlings, if transplanted once before being placed in their flowering positions, will bloom in the open during July and August.

Intermediate and East Lothian Stocks.

These are practically forms of one type, and require a longer growing season than the ten-week set, while their flowering season is correspondingly longer. They are characterised by being dwarf, bushy, and much hardier than ten-week varieties.

For earliest spring flowering in the open it is necessary to sow during July and August, transplanting the seedlings to frames or boxes, or potting them singly or in threes in small pots, and wintering them in a frost-proof structure, finally planting them where they are intended to bloom during March.

For a display from June onwards the seeds are sown in gentle warmth during the early part of February, and the plants grown in a light, airy, and moderately warm pit until the end of March, when they are transplanted to unheated frames. This type of stock succeeds best in the cooler parts of these islands, and is nowhere seen to better purpose than in the north, particularly in Scottish gardens, where it forms a special feature in the autumn displays.



A BEAUTIFUL ARRANGEMENT OF STOCKS AND OTHER ANNUALS.

Brompton Stocks.

Unlike the foregoing, all of which are of annual duration, the Brompton and Emperor stocks are biennial, and require to be sown in June or July of the previous year. Treatment as indicated for the intermediates is advisable, because, unless on well-drained soils, stocks are best protected during winter; not that they are very tender, but an excess of moisture in winter works more havoc among them than either frost or snow. Brompton and Emperor stocks form huge bushes, and are most effective in large beds or grouped along with herbaceous perennials in beds and borders.

In addition to the foregoing we have in the Beauty of Nice stock a type that combines the erect, vigorous habit of the Brompton with the elegance and floriferousness of the ten-week. They are idea-

stocks for cutting or pot culture. Seeds sown in July give plants to commence flowering at the New Year; an early September sowing flowers towards the end of March, while, if sown about the middle of February, the plants flower towards the end of June and onwards. This latter class includes a number of beautiful varieties, all characterised by handsome branched, pyramidal heads. The most distinct are Abundance, rose-crimson: Almond Blossom, delicate carmine: Beauty of Nice, flesh-pink; Crimson King, crimson: Empress Elizabeth, bright rose-carmine: Mont Blanc, white; Queen Alexandra, rose-lilac; and Summer Night, dark violet.

Several of the finest white-flowered stocks are known by distinctive names, three of the best being All the Year Round, a glossy green, wallflowered-leaved variety, with heads of purest white flowers, on 18-inch stems, that remain effective for some two months. Princess Alice has grey-green leaves and enormous spikes, that reach a height of two feet. Bismarck is a newer variety with grand spikes of enormous double white flowers. These white stocks are all specially good for furnishing cut flowers in quantity.

Culture.

Stocks attain their highest development in ground that is deeply trenched and liberally manured. After placing them in their flowering quarters, every attention should be given by affording copious supplies of water during dry periods, and, if augmented by an occasional watering with liquid manure, the results will more than compensate for the additional labour bestowed.

Thomas Smith.

Coombe Court Gardens.

CHOICE TREES AND SHRUBS IN WESTERN GARDENS.

The view in the Japanese garden at Watermouth Castle that we have the pleasure of illustrating herewith possesses much beauty, and is of considerable interest as an object-lesson of great practical value in the creation of distinct and pleasing effects in the garden. It admirably shows that in the formation of this feature of the grounds, which forms so delightful a setting to this fine Devonshire seat, the planter did not select from trees that properly belong to the woodland. It is not less evident that he also avoided shrubs whose chief merits consist in their robust habit and capacity for thriving under adverse conditions. We are, indeed, able to see at a glance that those only which attain dimensions suited to the positions they occupy, and are more or less ornamental, were utilised. Few of the many kinds that have a place in the Japanese garden can, for obvious reasons, be seen, but these few include the Japanese maples, pittosporums, dracænas, bamboos, and palms, all of which are well suited for gardens in the more favoured districts of the United Kingdom.

VIEW IN THE JAPANESE GARDEN, WATERMOUTH CASTLE.

The pittosporums are distinct in character and highly attractive, but there is considerable difficulty in growing them with a full measure of success, other than in the western counties of England and some parts of Ireland—Castlewellan, for example—where they are within the influence of the sea air. In the gardens of Devon, Cornwall, and other counties where they thrive without other than ordinary attention, such species as P. Mayi, P. undulatus, and P. ugenoides variegata attain a large size and form an attractive feature. Dracæna indivisa, which is represented at Watermouth Castle by finely developed specimens, requires genial climatic conditions, and the area over which it can be successfully grown is restricted. In gardens where it is known to thrive, this graceful dracæna should be planted, but it is a waste of effort to attempt to grow it where the conditions are not particularly favourable. The palm of which a leaf is seen peeping over the shrubs is Chamærops excelsa, and this handsome species is hardy enough to be grown over a wide area, provided sheltered positions are assigned the specimens in the less favoured districts.

The Japanese maples are remarkable for their elegance and the diversity of both the form and colour of their leaves, and, as they are hardy, they form a highly valuable group from which to select for garden planting. They are all of moderate growth, and are therefore suitable for gardens of quite moderate size, as well as for those which extend over a considerable area. The following forms of Acer palmatum are of quite exceptional merit, namely atropurpureum, dissectum, linearilobum, atropurpureum, palmatifidum, and sanguineum. Then in gardens that have the advantage of a kind climate might be planted more freely than has yet been the case such shrubs and small-growing trees remarkable for the beauty of their flowers as Eucryphia pinnatifolia, Fremontia californica, Carpenteria californica, Halesia tetraptera, or Snowdrop Tree; magnolias such as M. conspicua, M. Lennei, M. Soulangeana, M. stellata, and M. Watsoni, Styrax obassia, and S. japonica. Ceanothus azureus, C. dentatus, and C. thyrsiflorus may be mentioned as useful, free-flowering, and attractive.

RECENT ADVANCES IN HORTICULTURE.

(Continued from page 139.)

Horticultural Education.

Lastly, I come to what is, perhaps, after all, the most important aspect of the matter, viz., the education of the young gardener, for on the keeping up of the supply of capable, well-trained young men a great deal of the future success of horticulture will depend. I need not say very much about this, for last session we had a discussion on this important matter, introduced by Mr. Comfort, with a paper on the practical training of the gardener, and one by the secretary on their technical education. I will therefore merely refer here to what is being done by way of providing facilities for horticultural education.

As you are aware, the setting up of educational machinery for the teaching of horticulture is of comparatively recent date. For generations agriculture has been taught in our universities and colleges, and even forestry, under the name of arboriculture, had a place in these courses; but horticulture had no such position. Nevertheless, horticulture, so far as the practice of it went at any rate, has always taken the lead, and even agriculture has been indebted to it for much light and leading. Forestry has now been separated from agriculture in our teaching institutions, and recently horticulture has also received due recognition in this way. In Edinburgh we have, perhaps, the best equipped college—the Edinburgh and East of Scotland College of Agriculture—in the country for the teaching of the subject, and quite recently a demonstration garden, with an efficient staff, under the direction of Mr. Berry, has been added to its equipment. It is right, I think, that Edinburgh should take the lead in this, for it has long been associated with horticulture, and in no other city or town of Scotland has gardening and nursery work been so extensively pursued as they have been in its vicinity. But all over the United Kingdom horticulture is being taught, if not in colleges, then in schools; in fact, school-gardening is becoming universal all over the country. One excellent feature of the teaching of the practice of horticulture in the colleges in this country is that it is to a large extent in the hands of practical men, and in this respect it is a long way ahead of forestry, which, in Scotland at any rate, is almost entirely in the hands of men who know nothing, or next to nothing, about the practice. So far as horticulture is concerned, this is as it should be, for no practical subject, such as horticulture is, can be efficiently taught unless the teacher himself has gone through the mill, and knows all the details of it.

Individual Application.

But there would be little use for technical training, little use, in fact, in trying to improve the education of the gardener in any way, unless he can effectively utilise the knowledge which has been imparted to him. Unless he can use his reasoning powers and his powers of observation, as the old gardeners did, his technical education will avail him nothing. Gardeners' wages, compared with the remuneration given in many other callings, demanding not more intelligence, and certainly not more skill, are low. This is a matter which we hope will soon right itself, but it is quite obvious, if the position of the gardener is to be improved, that he must not rest on his oars and allow everything to be done for him. He must do something for himself. He must not rely on being spoon-fed in his education. It was not thus that the old gardeners won their way to the front rank in their calling, and it is not thus that the young gardeners will succeed. I have said that a great deal of the future success of horticulture will depend on the keeping up of the supply of capable, well-trained young gardeners. It therefore behoves them to embrace every opportunity to improve themselves if there is to be an advance all along the line in the future as there has been in the past.

Conclusion.

I have laid before you some of the main facts regarding the progress of horticulture in recent years. What of the future? Is this progress to be maintained? I have no fear for the future. I believe that, great as the progress in the past has been, the progress in the future will even be greater, for with all the advantages we now enjoy in the way of improved methods, with all the accumulated knowledge acquired from practical men who have gone before us, and with the scientific knowledge which is being imparted to us by our teachers of the present day, it cannot be otherwise. Horticulture, I believe, has a great future in store for it, and in its development I believe that this association is destined to take a leading part.

GARDEN DAHLIAS.

(Continued from page 130.)

We have several more sections that suit our purpose, and will next take the "Pompon."

This, admittedly, is quite another style of bloom to any of the former, but nevertheless quite suitable for the garden, providing they are grown naturally. It is a wide step between the pæony-flowered and these, but their very dissimilarity makes them a happy change. In growing the various types one may be tempted to use them as an edging to taller growers, but that is not advisable. These perfectly-formed and charming little flowers have a character all their own, and as such should be given beds to themselves.

Where tub gardening is practised they are ideal. If so used, strict attention must be paid to staking, and still more to watering. The dwarfer growers should be selected for this purpose. A good dozen are Bacchus, Bonella, Evelyn, Tommy Keith, Little Beeswing, Pink Beauty, Blush Gem, Ideal, Darkest of All, Daisy, White Aster, and Nerissa, and, just mentioning that the first four are the best for tubs, we pass on to the "Singles."

These are beautiful old favourites, and the newer giant forms look very attractive when arranged for exhibition. The singles, in addition to being an undoubted asset to the dahlia garden, are probably the best of all for associating with other plants, such as in the herbaceous borders.

I do not think, however, that they will increase in favour (as the collarettes have supplanted them for the garden) unless the new giant forms alluded to above, and of whose habit I am unfamiliar, should reinstate them. A few we liked last year were Snowdrop, Crimson Prince, Mrs. W. Wood, Nimrod, Mrs. W. W. Merry, Peggy, Princess of Wales, Serita, and Little Othello. The latter, with its very dark foliage and scarlet flowers, makes an uncommon and effective bedding plant.

Our next section is the new "Star," which are not, I believe, very well known. We had the nine varieties last year, which so far as I know are all that exist. The flowers are single with curled florets, and all have a white or cream ground, with picotee-like edging of different colours. They are exceedingly pretty and of good habit. These should make a useful addition to the singles for beds or mixed borders. They are appropriately named, each representing a star—Aries, Atus, Orion, Jupiter, Mercury, Neptune, Polaris, Saturn, and Venus. The favourite with us appeared to be Jupiter.

Now, in conclusion, I should like to refer to a sweetly pretty section known as the "Dwarf Bedding Cactus."

These we procured from Messrs. Dobbie, and are, I believe, of Continental origin.

A more delightful subject for bedding it would be impossible to imagine, and I anticipate that when better known they will become immensely popular. In habit the plants are dwarf and bushy, growing about twenty inches high and for the most part flowers of extreme delicacy of colouring. The varieties are Amanda, Citronenvogel, Goldperle, Edelweiss, Faunkonig, Gluchant, John Mortenson, Perkeo, Quelle, and Zwergsonne, with a new introduction named Marianne.

Though not strictly of this type, a favourable word must also be given for Barlow's Bedder, a scarlet variety of much merit. And here a passing reference to the dwarf show bedders, noting the variety Rising Sun, as being especially good, concludes my list.

From this list it must be admitted we have ample choice for all tastes and gardens. For large gardens, where a bold display is necessary, the pæony-flowered take pride of place, followed by the decoratives and collarettes, the others being used discriminately. For small gardens it may be necessary to omit the giant decoratives and taller pæonies.

If I may give my ideas as to what would increase the popularity of garden dahlias, I would say grow them early, so that they reach the flowering stage before autumn. If the same attention which is ungrudgingly given to many summer bedding plants were bestowed on the dahlia, I feel sure they would soon be much more largely grown. I overheard some ladies remark at the R.H.S. Hall the last week in August that it was sad to see so many dahlias, naturally inferring that we were reaching the end of the season. That seemed to sum up the situation. They are looked upon as typically autumn flowers, and often late autumn at that. It is quite possible to have a good sprinkling of bloom early in July, but not if they are planted out of 3in. pots the first week in June. To me it is sad to see them commencing to bloom at the end of September, with the possibility of their being cut down any night by frost.

We endeavour to have our cutting plants well established in 5in. pots up to 9in. according to size, by planting time. They are then ready to grow right away without a check. Amateurs with little convenience should make efforts to pot their plants on after receiving them from nursery. I should also like to mention that I do not agree with digging in a lot of manure. Our ground had a mere scattering of colliery manure last year, and none in 1911, but during that memorable year of sunshine we gave repeated mulchings of grass from the mowing machines. I trust that many, who like myself look forward to a good dahlia season will not be disappointed.

Potatoes.—For affording an early supply sets of a quick maturing variety may now be planted on a warm border, the soil of which was dug or bastard trenched two months or longer ago; it is advisable to prick over the surface with a fork to provide a fine tilth. In planting the border deep drills should be drawn or chopped out at 2ft. apart, the sets being dropped at a distance of 1ft. apart and five or six inches below the ground level; fill in the soil so that a slight ridge be left to mark the row. Medium-sized sets, which have been sprouted under cool conditions, are the most suitable. The following varieties are excellent earlies to select from: May Queen, Ringleader, Sharpe's Victor, Sharpe's Express, and a good type of the old Ashleaf.—W. Messenger.

Late planted Standard Fruit Trees.—These will need to be shortened more or less, according to the length and strength of the growth and quantity of the roots. Cut the shoots just above an eye pointing in the direction the following season's growth is required, and spur the inner shoots to within two eyes of the base. If the weather should prove dry, mulch well over and about the roots, and see that ample moisture is applied until the fresh roots have taken to the new soil. Any trees yet to be planted should be thoroughly immersed in water for some hours before planting, otherwise failures may occur. Stake and make all trees secure against movement by wind, taking care to allow for the bark swelling when tying the stems to the supports.—H. Markham.

NEW, RARE AND CHOICE

HARDY FLOWERS FROM SEEDS

The Herbaceous Border and Rockery are now the most attractive feature of the garden, and no garden is complete without a fair collection of hardy plants. The raising of these beautiful plants from seeds is at once most interesting and economical. Keen and up-to-date amateurs should get

THOMPSON & MORGAN'S
58th Annual Seed Catalogue
which they will find of immense value and interest.

CARR STREET, IPSWICH.

WAKELEYS celebrated HOP MANURE

THE MOST PERFECT FERTILIZER FOR GARDENS, GREENHOUSES, LAWNS, Etc.

PATENTED.

THE ONLY RELIABLE AND COMPLETE SUBSTITUTE FOR STABLE MANURE

SCIENTIFICALLY AND CHEMICALLY PREPARED

in the form of a leaf-mould, ready for use at any time, in the same way, and for all purposes that stable manure is put. Goes further (1 cwt. equalling 15 cwts.), gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.

THE GARDENERS' MAGAZINE states: The difficulty of obtaining really good stable or farmyard manure is overcome by using Wakeley's Hop Manure. This supplies just the materials required for improving the condition of a soil, furnishing with needful humus, and providing the crops with the essential plant foods they require, viz., nitrogen, phosphates, and potash. **THOUSANDS OF TESTIMONIALS. PARTICULARS POST FREE.**

BEWARE OF IMITATIONS: GENUINE ONLY IN OUR MARKED BAGS.

AWARDED DIPLOMA AND MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912.

Sold in Bags, 28lbs., 2 3; 56 lbs., 3/6; 1 cwt., 6 -; 5 cwts., 28 9; 10 cwts., 55/-; we paying carriage to any station in England and Wales, or by carrier in London district (also, in not less than 1 cwt. lots, by London Boat to Scotland and Ireland). Through Nurserymen, Seedsmen, and Stores, or direct from the Manufacturers and Patentees,

WAKELEY BROS. & CO., LTD., 68, BANKSIDE, LONDON.

Also **WAKELEY'S GROUND GARDEN LIME**, 2/- bushel bag, Carriage Paid 25 miles, or 1/6 carriage forward.

By Special Appointment *To His Majesty The King.*

LAWN MOWERS. GREEN'S AND ROLLERS.

Highest Awards, Royal Botanic Society, Royal Horticultural Society, and numerous others.

STAND PRE-EMINENT.
Hundreds of Thousands in Use.

TREES AND SHRUBS FOR WINTER EFFECT.

During the dark winter days, when but few flowers except Christmas roses and the Algerian Iris stylosa are obtainable in the open air, any subjects that impart colour to the landscape are valuable. Of these no more effective examples can be cited than the red dogwood and the golden and cardinal willows, the bright tints of whose leafless branches afford exquisite colour harmonies. What good use can be made of these willows is exemplified at the Royal Gardens, Kew, where they are glowing on the island in the lake, and create a charming winter effect.

Jasminum nudiflorum, though, being a climber, it is ineligible for inclusion among trees and shrubs, can scarcely be passed over, since its wealth of golden blossom is produced in the depth of winter, and is particularly valuable for effect. The Winter Sweet (Chimonanthus fragrans) and Nuttallia cerasiformis, with small pendant flower clusters, winter and early spring bloomers, are not, although naturally desirable, especially effective, and this may also be said of the typical Mezereon, though the white-flowered variety is a more conspicuous object. The Witch hazel (Hamamelis) is an attractive winter-flowering small tree or shrub, its blooms, with their waving primrose-yellow petals and claret-coloured centre, on the leafless branches, being quaintly pretty, while early in February, before the first of the ordinary almonds, Cornus Mas produces its yellow, thin-rayed flowers, the effect at a little distance of a tree in full blossom being distinctly ornamental.

Wyndham Fitzherbert.

THE PLANTING OF TREES.

The question is raised in your issue of March 8 whether "careless" or rough planting, with the trees rammed into the soil, would be as beneficial in the case of forest trees as it has been found to be with fruit trees. If the explanation given of the results in the latter case is correct, it certainly should be so, and the following experiment, the details of which have not yet been published, bear this out.

In the early part of 1909 a plantation consisting of about 400 Scots firs, 700 larch, 200 spruce, 100 oak, and 100 elm was made at Milton Bryant, in Bedfordshire, half of the trees being planted in the most approved manner by the Duke of Bedford's forester, and the other half by ourselves in the rough manner indicated. The ground was divided into five alternating sections, two being planted by one of the parties, and three by the other. The choice of ground was given to the forester, as also was the selection of trees, after these had been divided into two equal groups. He was also given the advantage of settling the days when he considered that planting could be done, though, owing to labour arrangements, we could not always avail ourselves of good weather. Half of our trees were planted when there was water and snow standing in the holes, and when ordinary planting would have been out of the question.

The ground was exceptionally heavy, and the growth made by the trees was not good, but the rammed trees showed an excess of growth over the unrammed ones in the two seasons during which measurements were made, though not so great as the average found in our many experiments with fruit trees; it amounted to 4 per cent. in 1909, and 12 per cent. in 1910. The beneficial effect of the ramming, however, became more conspicuous when the mortality amongst the trees was recorded, this being, in 1909, 7.6 per cent., against 12.4 per cent in the forester's plots; and, in 1909 and 1910 together, 12.4 per cent., against 24.4 per cent. The treatment of the trees and ground after the planting was the same in both cases, and this was left entirely in the hands of the forester.

Of course, when discussing "careless" planting, it must be remembered that some forms of carelessness may produce very bad results, and injury to the roots, if carried beyond a certain point, will do so likewise. This has been dealt with fully in our reports.

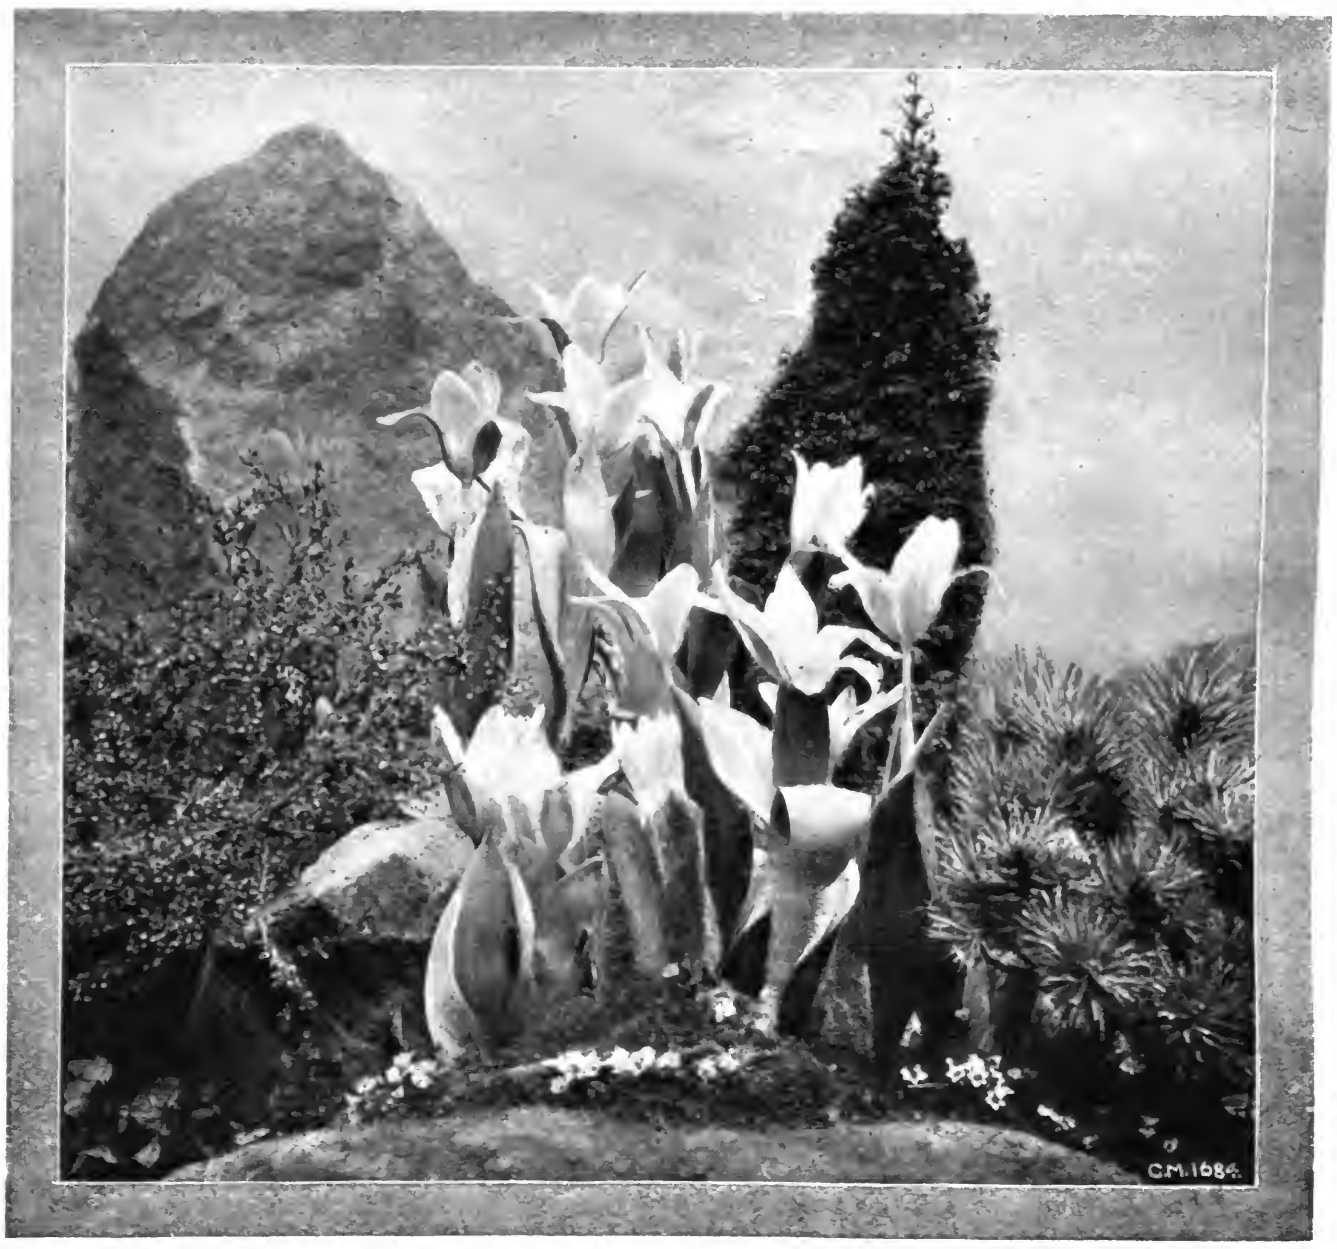
Spencer Pickering.

KAUFMANN'S TULIPS.

For some years subsequent to its introduction to European gardens Tulipa Kaufmanniana failed to produce much impression upon cultivators of hardy, bulbous and other plants, and, as a consequence thereof, a comparatively long period elapsed before it was generally distributed. This is not altogether surprising when we consider that for some years a dependence had to be placed upon imported bulbs, which were somewhat expensive, and not always quite satisfactory. Moreover, the species had, when growing in the garden, to compete with early varieties that were more showy in colouring, and obtaining at a small cost. Now that the bulbs are plentiful and inexpensive, and the distinctive characteristics of the species fully understood, it has obtained much favour from cultivators, and is annually planted in large numbers, more especially in warm, sheltered positions in the rock garden.

For several years past it has been freely staged by exhibitors at the early spring meetings of the Royal Horticultural Society, and, arranged in small groups, in association with other hardy plants that produce their flowers at the same season, they present an attractive appearance, and invariably receive a full share of attention. Messrs. Wallace and Co., of Colchester, invariably show this tulip with much success on the rockeries they arrange at the Horticultural Hall, and at the first of the meetings held this month the groups of tulips contributed materially to the interest and attractions of their rockery. Their arrangements, although always good, have evinced considerable diversity, and one of the greatest successes of the firm in presenting Tulipa Kaufmanniana to public notice on a small rockery is probably that illustrated herewith. It need hardly be said that the small coniferous trees which served the purposes of a background were of very small proportions.

Tulipa Kaufmanniana is a native of Central Asia, from whence it was introduced to cultivation in 1877, and it has improved materially under cultivation. The flowers are rather large in size, and elegant in aspect, and the broad reflexing petals are cream-white, marked and suffused with bright red on the reverse, and having a yellow base on the inner side. There are several distinct varieties, the most notable being aurea, a superb form, with deep yellow flowers; and miniata, an effective variety, with large red flowers. Both the species and its varieties are quite hardy, but as they bloom at an early period of the spring it is a decided advantage to plant them in rather sheltered positions, and thus avoid the risk of the flowers being injured by keen easterly winds.



A PRETTY EXHIBIT OF TULIPA KAUFMANNIANA,
Arranged at the Horticultural Hall by Messrs. Wallace and Co., Colchester.

Erica candidissima. — Of the greenhouse heaths that flower during the spring months, this is one of the best. It forms rather a bold, upright-growing bush, which bears a profusion of tubular-shaped blossoms of the purest white for some distance along the shoots. The foliage is rich dark green, and serves admirably as a setting to the pretty flowers.—S. W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

THE COOL HOUSE.—The odontoglossums are now making a good display in the cool house, and one cannot help noticing the great difference the hybrids have made in adding colour to this division. Up to about 5 or 6 years ago we depended almost entirely on imported species and natural hybrids for colour effect, and white flowers were always predominant. The many beautiful coloured hybrid odontoglossums, and the odontiodas have altered these conditions, and it is really surprising how rapidly this change can be brought about where the process of hybridisation is practised, even in private gardens. The costly kinds of a few years ago are now procurable for modest outlays, and, unless there are some special characteristics, the hybrids and coloured forms are as cheaply procured as the imported plants. I am enlarging on this point to some extent, because until the reasonable price of odontoglossums is fully realised there will be the unnecessary delay in their more general cultivation. It will be pretty generally realised in private gardens that, for all cut flower purposes, it is impossible at this season of the year to have anything more serviceable than good spikes of odontoglossums. The durability of the flowers and their decorative characteristics render them most useful at this season. Now that the plants are better understood, and greater satisfaction is obtained from their more successful cultivation, they are becoming more generally cultivated. There can be no doubt but that the cool treatment afforded during the winter months, when the bulk of the plants were in their more active growth, was the chief cause of failure in past times. A temperature of 50 degrees during winter has proved to be the more desirable treatment. There is one thing that should be at all times guarded against at the flowering season, and that is, leaving the spikes for too long a time on the plants after the flowers have expanded. Consideration is necessary, and the spikes should be removed before the plants show signs of distress by the shrivelling of the pseudo-bulbs.

POTTING.—At this season some of the plants may require potting as they pass out of flower, and others may have new growths and new roots. We have found that some of the plants call for attention at all seasons, and, with ordinary care, providing the new roots are ready to push into the new compost, very little trouble is found. The surroundings should be kept as moist as possible, and shade from strong light must be given until the plants have become re-established. The compost we find most suitable is equal portions of fibrous peat, finely chopped sphagnum moss, and broken oak or beech leaves, with sufficient sand and broken crocks added to render the compost porous.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

GHENT AZALEAS.—As these pass out of bloom the dead flowers must be picked off and the plants placed in a warm, moist atmosphere to finish their growth. Put other plants into the forcing house to keep up the supply of flowers; they will bloom in about three weeks from the time of placing them into heat.

INDIAN AZALEAS.—These must also be encouraged to make strong, healthy growth after flowering, and any repotting necessary may be done when they have passed out of flower. A compost of peat, fibrous loam, leaf-soil, and coarse sand will suit them. Azalea indica is very subject to red-spider and thrip, and to make sure they are clean they should be laid on their sides and thoroughly syringed with an insecticide, after flowering. Other shrubs which need attention at the same stage are lilacs, viburnums, laburnums, deutzias, etc. These must be given the protection of a cool house until they are plunged out of doors in May. Lilacs may be pruned hard back, and planted out in prepared ground. They will be ready for forcing again in two years.

FORCED BULBS.—When tulips and narcissi have flowered they should be placed closely together in cold frames. In the autumn they may be planted out in suitable places in the pleasure grounds.

IMANTOPHYLLUMS.—When well grown these are most useful subjects for the conservatory during the spring and early summer months. They are now throwing up their flower spikes, and will need plenty of water, which must be supplemented occasionally with stimulants. Liquid manure, soot water, and some approved fertiliser may be used alternately. When they have flowered any repotting necessary must be attended to. If well cared for in the matter of watering and feeding at the proper time, the plants will not need repotting for several years. They may be readily increased by division directly they have flowered. Provide a rich compost, and pot firmly. Place them in a warm house for a few weeks after flowering to encourage fresh growth.

WATERING AND SHADING.—The watering of plants under glass will require more frequent attention now that the days are longer and the sun's rays more powerful. Nevertheless, it will still be necessary to exercise judgment when applying water, and especially to plants flowering in the greenhouse or conservatory. The blinds will have been adjusted to houses containing flowering plants several weeks ago, and it will be necessary now to fix the blinds to all houses containing tender plants.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

PEACH AND NECTARINE TREES.—It is important to complete any further pruning and training that remains to be done, as the buds are now fast moving, and may yet be damaged when carrying out the work. Allow ample room for the full development of the coming season's growth. Keep the main branch straight from the tree stem at different angles to form an even-balanced head, and the young shoots straight from the base, so that when finished the whole of the wall space is covered with suitable fruiting wood, but do not be in too great a hurry to disbud when the new growth commences. If the trees are large, and have produced annually heavy crops of fruit, and extra nourishment is desirable to keep the trees in vigour, top-dress with good loam and bonemeal, first removing a portion of the top soil; on light well-drained land a good mulching with rich farmyard manure may be applied much earlier in the season than when the soil is of a heavy and retentive nature. Put late-planted young trees in order; first tread the soil over and about the roots, and prune and train to form a shapely head; do not train a shoot up the centre if a good fan-shape tree is required, and watch and regulate very carefully any shoot much stronger than the rest. In some cases it is the best to cut away entirely a strong growth which may (if left) completely spoil the whole of the future tree. Attend now to protecting materials should the weather prove severe.

FIGS.—Trees in bearing will need some amount of pruning annually, and those trained on walls should have their branches rather thinly trained, and be given ample room for extension. Aim as far as possible to secure plenty of short, sturdy fruitful wood, and, should the growths become too coarse, cut back some of the roots. Figs thrive best when the roots are somewhat restricted, and the soil firm, with plenty of old mortar added. In the more favourable parts, and where the soil is of a chalky nature, figs may be grown either as standards or in the form of bushes with success, and the most dependable variety in the open is Brown Turkey.

STRAWBERRIES.—The land intended to be cropped with plants that have been forced should be made ready, so as to allow for the soil to settle, as strawberries require a firm grip. Trench and manure heavily if the land is poor and gravelly, and give less manure if the soil is in good heart. Keep the permanent beds free from weeds, and mulch if desirable.

GRAFTING.—Whenever the sap is on the move, and the bark parts freely, grafting may be done. Pear trees on walls, horizontally trained, will need to have the branches cut back to within six inches of the stems, and the grafts inserted on the upper side, and should any of the grafts fail train a young shoot where desired, and bud when the right time arrives.—H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

PEAS.—Seed may now be sown on open quarters, and by selecting varieties which will form a succession several rows may be sown at one operation. The practice of sowing in well-prepared trenches is to be strongly recommended, and the enhanced return amply compensates for the extra initial time and labour spent. The seeds should be sown thinly, and sufficient space between the rows be allowed for due admission of light and air; overcrowding tends to spindly growth and inferior crops. Plants from the autumn sowing will be sufficiently advanced for sticking, and protection may be necessary from the ravages of birds.

SPINACH.—Sow on a warm border to follow the winter crop. The soil should be in good condition, and well pulverised. Before sowing afford a dressing of soot and wood ashes, which should be well raked in. Sow in drills a foot apart. Thin out the young plants as soon as they can safely be handled. Further sowings may be made on open quarters any time during April and onwards, according to requirements.

TOMATOES FOR OUTDOORS.—To have good, sturdy plants for putting out in the open by the end of May a sowing should be made forthwith. Sow the seeds thinly in pans or boxes, in light sandy soil; cover with fine soil, and place in a temperature of 60 deg.; providing the soil is moist, no water need be applied until the seedlings appear. Cover the seed boxes with a brown paper, removing this as soon as the young seedlings come through the the soil. When two rough leaves are developed, put the seedlings singly into 4in. pots, using a mixture of three parts loam, one part leaf-soil, one part spent mushroom bed manure, and a little wood ashes and mortar rubble or sand.

REMARKS.—The time will soon be at hand for the outdoor sowing of various kinds of vegetable seeds, and the preparation of the surface soil should be carried out a few days previous to sowing time. Soils which readily provide a good seed bed should have a dressing of soot and wood ashes well raked in. In dealing with those of a heavy, retentive character, it will be necessary to have in readiness a good supply of finely-sifted soil for covering the seeds. It is a good plan to roll the seeds in slightly moistened red lead, as this acts as a deterrent to the attack of mice and birds, and also enables the sower to note the quantity of the seeds sown. A slight dressing of nitrate of soda or sulphate of ammonia will materially assist quick growth in young cabbages, but care must be taken to avoid touching the plants with this manure.—W. Messenger, Woolverstone Park Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

From one end to the other the Royal Horticultural Hall was packed with exhibits on March 18, and even the annexes were well filled. The attendance was good, but scarcely so large as on recent occasions. Daffodils figured largely, and orchids were brilliant. Hardy flowers and forced flowering shrubs bulked largely, and were very showy, and there were numerous rock gardens. Carnations and tulips were also very much in evidence. One daffodil, five orchids, and two hardy plants gained awards; probably the most interesting plant was Primula Purdomi, a quite new species from China, and supposed to be hardy. It has rosy lilac flowers, and mealy stems and leaves, and it was shown by Messrs. J. Veitch and Sons, and gained a F.C.C.

FLORAL COMMITTEE.

A glorious group of flowering shrubs from Messrs. J. Veitch and Sons attracted general attention because of its mass of gorgeous bloom. Pink Pearl and White Pearl rhododendrons filled up the centre, and round these were grouped golden laburnums, white viburnums, mauve wistarias, orange and yellow Mollis azaleas, deutzias, lilacs, pyruses, amygdalus, and forsythias. Unusually brilliant were the handsome trusses of rhododendrons which Messrs. Gill and Sons, Falmouth, staged with a colony of Primula Winteri, and a few flowering plants of the rare Myosotidium nobile. Among the rhododendrons the outstanding varieties were R. corrubia, R. ciliatum, R. barbatum, R. Harrisi, and R. arboreum.

Tree peonies were well exhibited by Mr. Amos Perry, Enfield, with a background of Japanese maples; Archiduc Ludovic, pink; Elizabeth, salmon; and Louis Monchelet, lilac, were three first-rate varieties staged. Forced pyruses and cherries were grouped in the orchid annexe by Messrs. J. Piper and Sons, Bayswater and Barnes, with bamboos and maples.

Messrs. Wills and Seegar, Onslow Crescent, South Kensington, who seldom exhibit, had a brilliant group of Mollis azaleas, blue hydrangeas, pyramidal and dwarf standard Indian azaleas, a sheaf of pink, buff, and red gerberas, and some grand examples of Phœnix Roebelini. From Messrs. W. Cutbush and Son, Highgate, came a fine bank of forced shrubs, which were arranged in masses.

Messrs. Wm. Paul and Son, Waltham Cross, were represented by roses in pots, grouped with small plants of Choisya ternata in bloom. Juliet was the rose most extensively shown, and its freedom was amply demonstrated. Mrs. Chas. Hunter, a deep reddish rose H.T. variety, was also well shown, and its shapely buds were much admired. Early roses from Mr. G. Prince, Longworth, made a pretty display.

The group from Messrs. H. B. May and Sons, Upper Edmonton, contained a large variety of clematises arranged in panels, which were broken up with nephrolepis and other ferns, and presented a highly attractive appearance. Messrs. H. Cannell and Sons, Swanley, had a bright display of zonal pelargoniums, chiefly single varieties, arranged in pans. A few of the most conspicuous were Uranus, Eldebert Hawes, Lady Warwick, St. Louis, Sir R. Ball, Countess of Jersey, and Dublin.

Acacias, notably A. armata, A. Drummondi, and A. armata pendula, were conspicuous in the group of greenhouse plants set up by Messrs. Stuart Low and Co., Enfield. Boronia megastigma added fragrance, and a good set of carnations with Baroness de Brienen and British Triumph as the great features. Cactus-flowered cinerarias from Messrs. Jarman and Co., Chard, showed a considerable range of colour, and the attention paid them gave evidence of the popularity of this strain.

Mr. A. F. Dutton, Iver, Bucks, had a nice display of baskets and vases of his new carnation Mrs. A. F. Dutton, which was in fine form and colour; while Mr. C. Engelmann, Saffron Walden, staged good examples of Carola, White Wonder, Sunstar, Triumph, and Lady Northcliffe carnations arranged in tall stands; also vases of Rex, Fanny, Benora, and Elektra. Messrs. W. Wells and Co., Merstham, were represented by a small exhibit of carnations. The best forms were Northport, R. F. Felton, Salmon Enchantress, and Benora.

Messrs. Young and Co., Cheltenham, had some good carnations, which were very fine in colour. The most conspicuous varieties were Empire Day, Lady Neild, Mikado, Hon. J. Boscawen, Duchess of Devonshire, and Wivelsfield Wonder. Messrs. W. Cutbush and Son, Highgate, staged a bright group of carnations, in which the red variety, Mrs. Mackinnon, was particularly attractive.

Carnations from Mr. H. Burnett, Guernsey, were very fine, and Baroness de Brienen, Marmion, Mrs. C. F. Raphael, Lady Northcliffe, and Mrs. Tatton were varieties of great excellence and beauty. A gay group of perpetual carnations from Messrs. Allwood Brothers, Haywards Heath, contained large vases of fine flowers of Mary Allwood, Marmion, Triumph, Scarlet Glow, Wivelsfield White, Rosette, and Mrs. C. W. Ward.

Mr. R. d'E Day, Sutton Scotney, Hants, gave a fine display of Spanish irises, staging about twenty feet run in large vases. They were remarkably well developed for the early period. The varieties were Raphael, Louise, Flora, Belle Chinoise, Monche d'Or, and Bronze King. Messrs. Thompson and Charman, Bushey, Herts, also contributed a pleasing exhibit arranged with stone. A pleasing patch of Daphne cneorum major was attractive, as were also the groups of primulas, ericas, and Corydalis Halleri.

In the annexe Messrs. J. Cheal and Sons, Lim., also had a nice exhibit of hardy plants arranged in a natural style. Various conifers were employed on the mounds raised, as did also acers, rhododendrons, and genistas; while in the nooks were primulas in variety, aubrietias, Lithospermum prostratum, and hepaticas. The ericas employed here were very good. Mr. G. Reuthe, Hardy Plant Farm, Keston, Kent, sent a fine display of hardy flowers and shrubs. Rhododendrons figured largely both as cut flowers and plants. Saxifragas were to be seen in large variety, as were also hepaticas, narcissi, Anemone pulsatella, and some camellias.

A remarkably bright exhibit of hardy flowers came from Mr. M. Pritchard, Christchurch, which were arranged in masses. Primula Sieboldi was represented by several varieties, while the aubrietias included such varieties as Mrs. Lloyd Edwards, Lilac Queen, Hendersoni, and deltoides grandiflora. Primulas capitata, frondosa, and viscosa were excellent, while the saxifragas were nicely flowered and tastefully grouped.

Messrs. R. Tucker and Son, 16, George Street, Oxford, contributed a display of these plants. Primulas were exhiited in good form, as was also Soldanella montana. The saxifragas, too, were interesting. From Mr. G. W. Miller, Clarkson Nurseries, Wisbech, came quite a spring display, which included polyanthuses and primroses, giant daisies, hepaticas, and narcissi. The polyanthuses were remarkably fine, and especially as they had not been sheltered.

The Wargrave Plant Farm, Lim., Twyford, Berks, also exhibited a double rock garden, or, in other works, a display that occupied a double table. The best features were Ranunculus creticus, pale yellow; Draba azoides, Primula Winteri, P. megasæfolia, Myosotis Ruth Fischer, Mazus rugosus, and Megasea Strachyi. The dwarf conifers employed were tastefully arranged. A distinct style was adopted by Mr. H. Hemsley, Crawley; he relied rather more on his plants than on his exhibit of sandstone. Some of the most prominent features were Lithospermum purpereo cœruleum, Viola gracilis, Gentiana acaulis, Hepaticas in variety, some fine examples of saxifragas grown naturally, with an appropriate background of berberis in variety, pinus, and dwarf-growing conifers.

Mr. Clarence Elliott, Six Hills Nursery, Stevenage, again presented a bold display, which did not contain examples of everything in the nursery, but a natural display which was much admired. Saxifragas apiculata, S. Boydi, S. oppositifolia, and S. o. splendens were all well represented, as were also Anemone Pulsatilla, Morisia hypogæa, Viola gracilis, and aubrietias. From Messrs. G. Bunyard and Co., Lim., Maidstone, came a naturally-built rock garden, which occupied a broad space, and was not overcrowded. Some of the most attractive plants were the fritillarias, saxifragas in variety, anemones, aubrietias, and primulas. The hardy ericas and Andromeda floribunda were effectively used.

Mr. Jas. Box, Lindfield Nurseries, Haywards Heath, occupied one of the corners of the hall with a fine rock garden display, which was admirably staged. In the background were to be seen acers in variety, berberis, cedrus, and bamboos, while grouped lower were to be seen Primula denticulata, P. malacoides, P. Winteri, P. viscosa, and a variety of P. acaulis. Hepaticus, Anchusa myosotidiflora, saxifragas, and Phlox pilosa all contributed to the general good effect. From the Burton Hardy Plant Nurseries, Christchurch, came a nice display of hardy plants, tastefully arranged. The primulas being quite a feature, various forms of P. denticulata were staged, while P. nivalis alba, P. frondosa, P. integrifolia, P. viscosa purpurea, and P. Kitaibeli were also in good form.

Bedded in moss, associated with a few dwarf conifers, and planted in goodly colonies among rocks, Messrs. J. Piper and Sons, Bayswater and Barnes, presented Primula frondosa, a sweet little alpine, P. denticulata, and P. d. alba, P. rosea, P. Winteri, Ranunculus amplexicaulis, and Caltha palustris fl.-pl. Morisia hypogæa was a fine feature of the group of alpines set up by Messrs. G. Jackman and Son, Woking; Thalictrum anemonoides, with its dainty white blossoms, and Anemone pulsatilla alba were other specially good things.

Messrs. Whitelegg and Page, Chislehurst, had a rock garden exhibit of considerable extent; choice subjects planted in the cosy corners were Primula Forresti, P. J. J. Wilson, P. Veitchi, and aubrietias. Of special interest was Viola gracilis lutea, a soft yellow form of the popular V. gracilis. Messrs. T. S. Ware, Lim., Feltham, also contributed a rock garden exhibit, and furnished it prettily with Thalictrum anemonoides, Gentiana acaulis, Saxifraga Faldonside, Silene Hookeri, Erysimum helveticum, trilliums, and primulas. The Guildford Hardy Plant Company, Guildford, sent saxifragas, New Zealand veronicas, Primula frondosa, and many dainty alpines.

The little exhibit of alpines, etc., arranged in the form of a rockery mound by Messrs. Barr and Sons, Covent Garden, was furnished with Anemone pulsatilla, Primula denticulata, fritillarias Narcissus triandrus albus, N. Bulbocodium saxifragas, and scillas. Fragrant violets and rich-hued primroses and polyanthuses were displayed by Messrs. Blackmore and Langdon. Among the former the new single Askania, deep purple, was especially prominent, and is a large variety.

Messrs. Sutton and Sons, Reading, presented a display of growing grasses that attracted more than ordinary attention from the visitors. The various species were growing separately in boxes, on specially-prepared fabric, which was evidently to their liking.

for they were most striking. Dried specimens were also exhibited to illustrate their root action; while in front were to be seen examples of soils best adapted for their growth. A collection of fertilisers and pest destroyers was also exhibited, and, as most people are troubled with their lawns in some way or other, the attendants were kept quite busy.

ORCHID COMMITTEE.

An interesting exhibit from Messrs. Armstrong and Brown, Tunbridge Wells, contained a number of very pretty dendrobiums, and though most of the plants were somewhat small, they were splendidly flowered. Cymbidium Ballianum, with three spikes of white flowers, and C. ebuneo-Lowianum, with three spikes of creamy flowers, formed a centre round which some odontoglossums and a number of yellow lælio-cattleyas were arranged. Among these latter there were L.-c. Myra and L.-c. Ernesti, both very bright hybrids. Some good odontiodas were also included in the exhibit. Messrs. Hassall and Co., Southgate, exhibited the ivory-white, long-tailed Angræcum sesquipedale, with various odontoglossums, the Brasso-cattleya Menda, and the huge-lipped B.-c. Veitchi.

Messrs. Sander and Sons, St. Albans, contributed Cymbidium insigne and a number long spikes of odontoglossums. Cattleya Schroderæ was very well shown, and Brasso-cattleya Mrs. Leeman was in good form. A batch of Renanthera Imschootiana lent brilliant colouring, as also did Masdevallia Pourbaixi, of which a large plant was shown. Trichopilea suavis and odontiodas were other prominent features. Mr. H. A. Tracy, Amyand Park, Twickenham, had a group of orchids that was gay with the golden Oncidium concolor, and included Oncidium Cavendishianum and Odontoglossum Pescatorei album. Mr. Edward V. Low, Haywards Heath, sent Lycaste Skinneri alba, and a fine form of Cattleya Schroderæ. Mr. E. H. Davidson, Twyford, showed the very handsome Cattleya Suzanne Hye, Orchid Dene var.

A fine group of orchids from Messrs. Charlesworth and Co., Haywards Heath, had many very handsome things in it. Odontioda Charlesworthi was beautiful, and O. Bradshawiæ with five good spikes, the lovely Phaius simulans, and the rich purple Lælio-cattleya Dominiana Prince of Wales, Cattleya Suzanne Hye, and some capital dendrobiums. In Messrs. Stuart Low and Co.'s group of orchids Cattleya Schroderæ, C. S. alba var. Purity, L.-c. Dominiana, C. intermedia alba, were associated with dendrobiums and oncidiums. De Barri Crawshay, Esq. (gardener, Mr. Stables), Rocefield, Sevenoaks, exhibited Odontioda carnea, O. Charlesworthi, O. Bradshawiæ, the graceful Odontoglossum Nerissa, and the yellow O. Harvengtense.

F. Menteith Ogilvie, Esq., The Shrubbery, Oxford, gained a F.C.C. for Brasso-cattleya Cliftoni magnifica, and an A.M. for the handsome purple and gold-lipped C. Tityus Shrubbery var. Sir George Holford (grower, Mr. Alexander), Tetbury, Gloucester, showed Cattleya Magnet (C. Mossiæ x C. Whitei), a deep rose-purple hybrid, that gained an A.M.; Brasso-cattleya H. G. Alexander, a novel hybrid between Brassavola Digbyana and C. citrina, was also shown from the Westonbirt collection. A small group of cut flowers of dendrobiums was arranged by Mr. Collier, gardener to Sir J. Colman, Bart., Reigate; D. Lady Colman was one of the finest varieties. A grand plant of Odontoglossum crispum Cobb's var. was exhibited by Walter Cobb, Esq. (gardener, Mr. C. J. Salter), and gained an A.M.; the flowers are white with a brown blotch on each sepal.

Large specimens of Odontoglossum Rossi majus and O. pulchellum from Sir Trevor Lawrence, Bart., Dorking (grower, Mr. W. H. White), consisted of plants that have been about 30 years in the Burford Lodge collection. A Cultural Commendation was awarded.

DAFFODIL AND TULIP COMMITTEE.

Messrs. Barr and Sons, Covent Garden, had a brave show of daffodils, and besides staging beautiful blooms of well-known sorts they set up fine flowers of King Alfred, Lord Roberts, Sycovax—a beautiful cyclamineus hybrid; Golden Arrow, another attractive golden cyclamineus seedling; a considerable number of unnamed new seedling Ajax and incomparabilis varieties, the brilliant Blazing Star, and the orange-cupped Gadfly. A bright exhibit of daffodils and tulips from Messrs. R. H. Bath, Wisbech, was notable for the wonderfully fine flowers of Madame de Graaff, Ivernia, Princess Ida, and Bernardino it contained. La Reve was conspicuously good among the tulips.

A beautiful group of daffodils, chiefly new varieties, and many of them as yet unnamed, was set up by Mr. Alex. Wilson, Shovell, Bridgwater. Rubellite, which we figured last year, was in fine form; Cedric, a giant incomparabilis; Sunflower, with a wide crown-like cup, nearly as broad as the perianth; Judith, a giant Leedsi, with sulphur-yellow crown (A.M.); Elizabeth, a lovely triandrus hybrid; and Dragoon, white with orange-red crown, were but a few of the many lovely things in this group.

Messrs. Jas. Carter and Co., Raynes Park, had a beautiful and novel exhibit. It was another of their spring gardens. In front of a yew hedge, and on a raised bank, hundreds of lovely flowers of the golden-trumpet daffodil, Sir Francis Drake, were grouped with a margin of blue squills. At either end tulip La Reve was massed. In the centre a paved court had a pool and fountain, and on either side were huge leaden vases of Sir Francis Drake daffodil; while all along the foreground extended grass of the loveliest green imaginable. Flambeau is a brilliant daffodil, and, provided a bit of rare colour in the small group exhibited by Robert Sydenham Limited, Birmingham; Potent was another good thing; Victory and White Slave were in fine form, and a pot of N. calathinus was charming with its twenty, white, drooping flowers.

Messrs. Cartwright and Goodwin had an admirably arranged group of choice daffodils, with isolepis between the vases. A few outstanding varieties were Mdme. de Graaff, Incognita, Marshlight—rich orange cup; Van Waveren's Giant, Glory of Noordwyk, Salamander—very rich, and Gloria Mundi. Mr. F. H. Chapman, Rye, brought up a number of seedling daffodils, as well as charming flowers of Castile, Van Waveren's Giant, White Queen, Bernardino, Victory, Tennyson, Firebrand, and Bennett Poe. Mr. Chapman also showed a few of his unnamed triandrus hybrids, a group in which he has been very successful.

A splendid group of tulips came from Messrs. R. and G. Cuthbert, Southgate. These were arranged on the floor of the hall, but built in undulating groups, the whole presenting a fine appearance. Some of the brightest were Queen of the Netherlands, Prince of Austria, Maes, Ophir d'Or, Brilliant Star, Lady Borcel, La Grandeur, Le Reve, Adeline, and President Taft. Mr. W. A. Watts, Bronwylfa, St. Asaph, had beautiful blooms of several Welsh-raised daffodils, with Welsh names. Cenig, with broad, orange-rimmed crown; Hengan, yellow with orange-yellow crown; and Medlys, white with rich orange cup, were a few of the best.

Some very pretty daffodils were exhibited by Mr. Christopher Bourne, Bletchley, and among the many good things we noted Lady Moore, White Countess, Roxana, with broad orange cup; Sunrise, Orange Buffer, Fairy Queen, Duke of Bedford, and The Earl and The Doctor, two refined yellow trumpet varieties, quite new and beautifully frilled at the apex of the trumpet. Miss Warren, Canterbury, exhibited a number of seedling daffodils raised by the late Rev. G. Haydon.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. Westmacott and Co., 368, Strand, W.C., exhibited Cape fruits, that included capital melons, fine William pears, Hannepoot and Barbarossa grapes, pine apples, peaches, and plums.

Messrs. Sutton and Sons displayed a very fine lot of seasonable vegetables and set out in very tempting form a splendid lot of broccoli, cucumbers, radishes, lettuces, sea-kale, chicory, etc., that almost converted the visitors to vegetarianism.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Primula Purdomi, from Messrs. James Veitch and Sons, Chelsea; to Brasso-cattleya Cliftoni magnifica, from F. Menteith Ogilvie, Esq., The Shrubbery, Oxford.

Award of Merit.—To Odontoglossum crispum Cobb's var., from Walter Cobb, Esq. (gardener, Mr. C. J. Salter), Rusper, Horsham; to Cattleya Trianæ alba var. Sour. de Louis Verdonck, from M. Jules Hye de Crom, Ghent; to Cattleya Tityus Shrubbery var., from F. Menteith Ogilvie, Esq., Oxford; to Cattleya Magnet, from Lieut.-Col. Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury; to Narcissi Judith, from Mr. A. Wilson, Shovell, Bridgwater; to Omphalodes cappodocia, from Mr. Maurice Prichard, Christchurch, Hants.

MEDALS.

Silver-gilt Flora. — To Messrs. James Veitch and Sons, Chelsea, for cinerarias and flowering shrubs; to Messrs. Barr and Sons, Covent Garden, for daffodils; and to Messrs. R. and G. Cuthbert, Southgate, for tulips in pots.

Silver-gilt Knightian.—To Messrs. Sutton and Sons, Reading, for seasonable vegetables and salads.

Silver-gilt Banksian.—To Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Messrs. Westmacott and Co., Strand, W.C., for Cape fruits.

Silver Flora.—To Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to Messrs. James Carter and Co., Raynes Park, for a spring garden; to Messrs. W. Cutbush and Son, Highgate, for flowering shrubs and carnations; to Mr. G. Prince, Longworth, for roses; to Mr. L. R. Russell, Richmond, for clematis, etc.; to Messrs. Wills and Segar, South Kensington, for flowering shrubs, etc.

Silver Banksian.—To Mr. James Box, Haywards Heath, for rock garden; to Mr. Day, Sutton Scotney, for irises; to Mr. Clarence Elliott, Stevenage, for alpine plants; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons; to Messrs. Stuart Low and Co., Enfield, for greenhouse flowering plants; to Messrs. H. B. May and Sons, Edmonton, for clematis and ferns; to Messrs. J. Piper and Son, Bayswater and Barnes, for alpine plants; to Mr. M. Prichard, Christchurch, for hardy flowers; to Mr. G. Reuthe, Keston, for hardy plants; to Messrs. Sutton and Sons, Reading, for grasses; to the Wargrave Hardy Plant Farm Company, The Arcade, Liverpool Street, for alpine plants; to Messrs. Hassall and Co., Southgate, for orchids; to Mr. H. Tracy, Twickenham, for orchids; to Mr. C. Bourne, Bletchley, for daffodils.

Bronze Flora.—To Messrs. R. H. Bath, Lim., Wisbech, for daffodils and tulips; to Mr. F. H. Chapman, Rye, for seedling daffodils.

Bronze Banksian.—To Messrs. Allwood Brothers, Haywards Heath, for carnations; to Mr. G. Jackman and Son, Woking, for hardy plants; to Mr. Amos Perry, Enfield, for pæonies; to Messrs. Reamsbottom and Co., Geashill, King's Co., Ireland, for anemones; to Messrs. Young and Co., Cheltenham, for carnations.

SCIENTIFIC COMMITTEE.

Present: E. A. Bowles, Esq., M.A. (in the chair), Sir J. T. D. Llewelyn, Sir H. J. Veitch, Canon Fowler, Prof. W. Bateson, Messrs. J. T. Ledger, R. H. Pearson, E. M.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

PRUDENTIAL ASSURANCE COMPANY, Ltd.

Chief Office: HOLBORN BARS, LONDON.

INVESTED FUNDS EXCEED £84,000,000.

Summary of the Report presented at the Sixty-fourth Annual Meeting, held on 6th March, 1913.

ORDINARY BRANCH.—The number of policies issued during the year was **59,854,** assuring the sum of **£5,586,153,** and producing a new annual premium income of **£346,592.** The premiums received during the year were **£4,826,993,** being an increase of **£14,725** over the year 1911. In addition, **£5,893** was received in premiums under the new Sickness Insurance Tables issued during the year. The claims of the year amounted to **£3,626,469.** The number of deaths was **8,872.** The number of endowment assurances matured was **21,981,** the premium income of which was **£125,991.**

The number of policies in force at the end of the year was **901,838.**

INDUSTRIAL BRANCH.—The premiums received during the year were **£7,792,562,** being an increase of **£161,154.** The claims of the year amounted to **£3,070,271,** including **£324,797** bonus additions. The number of claims and surrenders, including **5,282** endowment assurances matured, was **382,734.** The number of free policies granted during the year to those policyholders of five years' standing and upwards, who desired to discontinue their payments, was **155,582,** the number in force being **1,809,171.** The number of free policies which became claims during the year was **52,296.**

The total number of policies in force in this branch at the end of the year was **19,140,743;** their average duration exceeds twelve and a half years.

The assets of the Company, in both branches, as shown in the balance-sheet, after deducting the amount written off securities, are **£84,571,932,** being an increase of **£3,332,250** over those of 1911.

In the Ordinary Branch a reversionary bonus at the rate of **£1 16s.** per cent. on the original sums assured has again been added to all classes of participating policies issued since the year 1876.

In the Industrial Branch a bonus addition will be made to the sums assured on all policies of over five years' duration which become claims either by death or maturity of endowment from the 7th of March, 1913, to the 5th of March, 1914, both dates inclusive, as follows:—

Premiums Paid for.	Bonus Addition to Sums Assured.
5 years and less than 10 years	**£5** per cent.
10 ,, ,, ,, ,, 15	**£10** ,,
15 ,, ,, ,, ,, 20	**£15** ,,
20 ,, ,, ,, ,, 25 ,, ...	**£20** ,,
25 ,, ,, ,, ,, 30 ,, ...	**£25** ,,
30 ,, ,, .. ,, 40 ,, ...	**£30** ,,
40 ,, ,, ,, ,, 50 ,, ...	**£40** ,,
50 ,, ,, ,, ,, 60 ,, ...	**£50** ,,
60 ,, and upwards.	**£60** ,,

The rate of bonus declared for last year has thus been maintained, and in the case of policies on which 25 and less than 30 years' premiums have been paid, and those on which premiums for 60 years and upwards have been paid, an increased bonus of £5 per cent. and £10 per cent. respectively will be distributed.

The Company took a leading part in forming Approved Societies under the National Insurance Act, 1911—Six Societies were founded, viz.: for Men, Women, Domestic Servants, Laundresses, Miners, and Agricultural and Rural Workers.

These Prudential Approved Societies have received a large accession of members, and as they will be administered in connection with the Prudential Assurance Company, the Directors regard their future growth and welfare with every confidence.

Messrs. Deloitte, Plender, Griffiths and Co. have examined the securities, and their certificate is appended to the balance-sheets.

A. C. THOMPSON, General Manager.
D. W. STABLE, J. SMART, } Joint Secretaries.

THOS. C. DEWEY, Chairman.
W. J. LANCASTER, W. EDGAR HORNE, } Directors.

BEST STOUT FRUIT NETS.—Do not be misled by so-called cheaper nets. Do not pay until you have seen and approved of nets. Send your order only. Netting, good strong, and small mesh. Will not rot. As supplied by me to the Royal Gardens. 25yds. by 1 yd., 1s.; by 2yds., 2s.; by 3yds., 3s. Any length or width supplied. Orders over 5s. carriage paid. List of testimonials and samples free. Only address, H. J. GASSON, The Net Works, Rye. Established 126 years.

Holmes, J. O'Brien, A. Worsley, G. Wilson, and F. J. Chittenden (hon. secretary).

ODONTOGLOSSUM x "SATURNE."—Mons. H. Graire, of Amiens, showed this curious hybrid between O. nebulosum and O. x Harryano-crispum. It closely resembles O. nebulosum in the form of the flowers, which are white closely spotted with light brown and rose.

ODONTONIA x "CYBELE." — Messrs. Charlesworth showed this cross between Odontoglossum cirrhosum and Miltonia candida grandiflora. Mr. O'Brien, with the aid of illustrations of both parents, called attention to the fact that the tubular labellum of Miltonia candida did not appear in the slightest degree, the broadly ovate spathulate labellum of the hybrid being perfectly flat. The colouring of the petals and sepals (broad bands of brown) were from the Miltonia, but the apiculate reflexed tips of the segments were as in Odontoglossum cirrhosum. The dark red lines characteristic of cirrhosum also appeared at the base of the labellum. A certificate of appreciation to Messrs. Charlesworth was proposed and carried nem. con.

NARCISSUS TRIANDRUS ALBUS x N. CYCLAMINEUS. — Mr. Chapman, of Rye, showed this pretty hybrid in which the cup was slightly paler than the perianth. It had a straight corona slightly cut at the mouth, while the perianth was reflexed. It flowered four years after the seed was sown, and Mr. Chapman's experience was that four or five years practically always elapsed between seed-sowing and flowering in these miniature narcissi.

HIPPEASTRUM "RUNNERS."—Mr. A. Worsley showed two small bulbs of a garden hippeastrum which had developed at the ends of short stolons bearing nodes and roots. Similar growths are normal in montbretias, and occasionally occur in snowdrops and leucojums.

VARIATION IN SEEDLINGS.—Mr. G. Wilson showed flowers of two orchid hybrids from the same seed pod. They were totally different in colour, one being of a brick red the other white with a few red spots.

EPIPHYTIC CYRTANTHUS.—Mr. W. E. Ledger showed some bulbs of a new species of cyrtanthus called C. dendrophilus from its being found wild on trunks of trees, such as species of podocarpus. Mr. Medley Wood wrote that it rooted among the moss on the trunks on which it grew.

CHIONOSCILLAS.—Mrs. Backhouse sent various chionoscillas with the original parents, Chionodoxa sardensis and Scilla bifolia, for comparison. The first generation showed no white in the filaments such as the chionodoxa shows, while they were midway in breadth between the two parents. The perianth colour contained just a suggestion of violet in the blue, giving it a different tone from that of the chionodoxa. The perianth pieces were about equally broad with those of chionodoxa. The seedlings from these varied a good deal in shade, some being quite blue, others purplish blue, and occasionally one appeared with white or whitish filaments, but these were usually coloured like the scilla. The flowers in the second generation were mostly broad petalled.

NARCISSUS WITH FRILLED TRUMPET.—Mr. Bowles showed flowers of a white narcissus with a frilled corona, and remarked that when the plants were newly divided the frill was as a rule not developed until two or three seasons of growth had been passed and the plants had become established.

Elstree and Boreham Wood Horticultural Society.

There was a capital attendance of members on the evening of the 13th inst., when Mr. E. Molyneux, V.M.H., of Swanmore Park, gave a lecture on "Herbaceous Plants" before the above society. The large dining hall at the Schools at Elstree was gratuitously placed at the disposal of the society by E. L. Sanderson, Esq., who also kindly consented to take the chair, which office he ably filled. As may be expected, the lecturer dealt with his subject throughout in a capable and efficient manner. His opening remarks referred to the definition of the word "herbaceous," and he advised those present who were exhibitors to carefully peruse their schedules, and make quite sure that only those plants were exhibited that complied with the regulations.

The herbaceous border, he said, might be in almost any position so long as overhanging trees were avoided. The question of size depended entirely on the circumstances, and unless the borders were very large planting in masses was not to be recommended. Climbing roses at the back of the border were, in the lecturer's opinion, some of the most suitable subjects to form a screen, or fruit trees could be used with advantage. The border, especially if the ground was heavy, should be trenched 3ft. deep, but on light soil this was not so necessary. Add plenty of light material and manure, and, if the subsoil was poor, leave it in the same place—the bottom. Planting on heavy soils was best deferred till spring, but on light soils the necessary division and planting was best carried out in autumn, preferably October. He also advised lifting some plants of such things as lychnis and chelones and storing them during the winter in boxes in a cold frame, especially if the soil was cold and heavy.

Mr. Molyneux strongly advised the inclusion of plenty of bulbs, such as narcissi, crocus, and snowdrops, for a spring display, and he urged the inclusion of the better varieties of Michaelmas daisies, montbretias, Chrysanthemum maximum, herbaceous phloxes, etc.

Numerous questions were put to Mr. Molyneux at the close of his lecture relating to suitable plants, choice of varieties, division and planting, etc. A vote of thanks was proposed by Mr. E. Beckett, V.M.H., and was warmly accorded. Several new members were elected during the evening.

United Horticultural Benefit and Provident Society.

The monthly committee meeting of this society was held at the R.H.S. Hall on Monday, March 10. Mr. Thos. Winter presided, and six new members were elected. The sick pay for the month, on the ordinary side, was £65 4s. 4d., and for the State section £22 3s. 4d. The committee deeply regretted to learn of the death of their old colleague, Mr. Wm. Woods, who for nearly thirty years was a member of committee. A vote of condolence was passed to the widow, and the sum of £46 19s. 9d. standing to his credit was passed for payment to his nominee. The sum of £48 8s. 2d. standing to the credit of the late Mr. Wm. Ford was also paid out. One member residing in the U.S.A. having reached the age of 70 was allowed to withdraw the sum of £104 12s. 9d., still leaving a balance of £10 standing to his credit. One lapsed member was allowed to withdraw £38 0s. 8d. standing to his credit. These sums give further evidence of the stability of the society. The annual meeting is to be held on April 14, 1913.

FORTHCOMING EVENTS.

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.
Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.
Ealing Horticultural Society, July 9.

Oswestry Flower Show, August 4.
Ranmoor Floral and Horticultural Society, Aug. 4.
Swanage Horticultural Society, August 4.
Westbury Horticultural Society, August 6.
Horsley Horticultural and Cottage Garden Society, August 16.

THE R.H.S. FORTNIGHTLY SHOWS.

The sameness of the rockwork exhibits at Westminster has been referred to many times in the Gardeners' Magazine reports of the R.H.S. meetings, and that by no means without just cause. To my mind, the worst point of all in connection with these groups is that they are so freely furnished with plants that have been forced prematurely into bloom, and thereby convey altogether a false idea of the display furnished by an outdoor rockery at this season. In many instances the plants must have been subjected to a good deal of artificial heat in order to have them in bloom, while those that flower naturally at this season have apparently, in most cases, been protected by frames.

This is altogether misleading to those who go to these meetings for inspiration, and no doubt leads to a great deal of disappointment, with totally uncalled-for blame falling on the poor gardener. A query often put is, Are these plants really hardy? and the questioner is, as a rule, assured that they are, which is partially correct and partially otherwise. Grown naturally, the plants may be hardy enough, but to imply that on an open rockwork they would be in the condition shown is quite another matter, and, as stated, is calculated in every way to mislead. No one can gainsay the floral beauty of many of the groups, but that is outside of the question altogether, as the exhibit is not what it purports to be, namely, a reproduction of a natural scene. S. W.

OBITUARY.

MR. GEORGE CLARK.

With much regret we record the death of Mr. George Clark, which recently occurred at his residence at Dover in his 62nd year. Mr. Clark, who was the senior partner and managing director of the firm of Messrs. G. and A. Clark, nurserymen, of Dover, took a keen interest in hardy plants, and was instrumental in bringing into prominence several possessing much merit.

ROOT-PRUNING BY DYNAMITE.

The writer witnessed an interesting experiment a few days since, which should be of value to some of the fruit growers. A number of healthy young apple trees are growing upon strong loamy soil, but they were growing too luxuriantly and did not fruit owing to their excessive root action.

For some time horticulturists in Australia and Canada, and the keen growers in the United States, have sought the aid of dynamite in breaking up subsoil for such purposes as planting trees, and also for further increasing the fertility of the soil, and in some cases had found the value of this agency for lifting the trees for root pruning. Mr. Holmes, ever on the alert, came across this method, and decided to become proficient in the use of the explosive. He sought practical advice upon the subject, and he is now master of what at first sight seemed a dangerous method of treating soil.

On the occasion of the experiment thirty-two trees were bodily lifted. It may seem rough treatment to the trees, but where a large number have to be done time and labour count for much, and furthermore, observations have proved that the plan answers just as well as the methodical way of digging round and cutting under the tree.

The method adopted is to bore with a stout crowbar a hole about 15 inches from the trunk to a point about 2 feet 6 inches deep, in a slanting direction, to about the centre of the tree. A cartidge with a long fuse is inserted, and the hole filled up and the soil rammed hard. A light is applied, and the operator has ample time to move away, just a few feet being sufficient. At the explosion there is an upheaval of soil, and the thick roots are torn asunder. It then takes but a few minutes to adjust the soil and make it firm again.

One could see that the force of the explosion descended as well as ascended. Thus, to make a hole for any purpose where hard soil exists the operation should prove beneficial. It would also be useful for removing old tree stumps that needed clearing. For these purposes it is certainly a labour-saver. The whole operation of lifting thirty-two trees took less than one hour. AYTCH PEA.

Prudential Assurance Company, Lim.—The annual report of this important company for the year ended December 31, 1912, is, as usual, of a highly satisfactory character, and affords evidence of remarkable activity in all the branches of its work. In the ordinary branch, the number of policies issued during the year was 59,854, assuring the sum of £5,586,153, and producing a new annual premium income of £346,592. The premiums received during the year were £4,826,993, being an increase of £14,725 over the year 1911. The claims of the year amounted to £3,626,469. The number of deaths was 8,872. The number of endowment assurances matured was 21,981, the premium income of which was £125,991. The number of policies in force at the end of the year was 901,838. In the industrial branch the premiums received during the year were £7,792,562, being an increase of £161,154. The claims of the year amounted to £3,070,271, including £324,797 bonus additions. The number of claims and surrenders, including 5,282 endowment assurances matured, was 382,734. The number of free policies granted during the year to those policyholders of five years' standing and upwards who desired to discontinue their payments, was 155,582, the number in force being 1,809,171. The number of free policies which became claims during the year was 52,296. The total number of policies in force in this branch at the end of the year was 19,140,743—their average duration exceeds twelve and a-half years. The assets of the company, in both branches, as shown in the balance-sheet, after deducting the amount written off securities, are £84,571,932, being an increase of £3,332,250 over those of 1911.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

RUST ON PELARGONIUM LEAVES.—M. K. M., Bedford.—I enclose some pelargonium leaves, which have a peculiarly rusted appearance on the underside. Is the trouble caused by fungi or insects? As many of the leaves have fallen, as a result, apparently, of this attack, I shall be very grateful for any information that will help me to cure the disease.—The rusty appearance is due to the presence of one of the rust mites, similar to, if not identical with, the one that often proves so troublesome with begonias. Remove and burn the badly-infected leaves, and dip the plants in tobacco water or a nicotine preparation, following this up with frequent dustings of all affected parts with tobacco powder.

BRITISH GARDENERS' ASSOCIATION—F., Liverpool: Will you be good enough to let me know the name and address of the secretary of the British Gardeners' Association?—With pleasure; Mr. Cyril Harding, Ulysses, Fortune Green, London, N.W.

LICHEN ON LAWN.—R. W., Broughty Ferry.—I shall be very pleased if you will let me know the cause of and the cure for a fungus (specimens enclosed), which appears in patches over the lawns. Our lawns appear, otherwise, to be in good order, and they receive a good dressing of bone-meal every second year. — The specimens are examples of a lichen, not a fungus, and the species is Peltigera canina. Its presence on the grass indicates a need for better drainage. Treat the infested patches as you would for moss, using an iron rake to remove the lichen, and scarify the soil. Follow this with a good watering of a solution made by mixing 1lb. of iron sulphate in three gallons of water. Subsequently dress the treated area with a finely-sifted sandy mixture of leaf-soil and old hotbed manure. We have been told that soot is useful in combating lichen growth in lawns; try frequent dressings on one of the patches, and let us know the result; in any case, soot is a fine fertiliser for lawns.

MEASUREMENTS OF A TENNIS COURT.—A. S., Rothesby: Will you kindly let me know in your next issue the proper measurements of a full-sized tennis court, and greatly oblige me?—This is a perennial question, one we have answered every year for many years past, and which we expect to be asked every succeeding year, especially as we all wish to spend as much as possible of the summer time out of doors, and lawn games are helpful in that direction. A full-sized tennis court is 78ft. long and 36ft. wide, but there must be a reasonable space outside these lines, especially at the ends, or good play will be impossible. The net divides the court in half, and should be attached to posts about 4½ft. outside the side line. Parallel with each outside line, and 4½ft. inside it, are the inside lines. Measure 21ft. from the net along each inside line, and join the points thus found; repeat this on the other side of the net, and then join up these cross lines (which should be 42ft. apart) by means of a central line. Where the latter joins the cross line it should be 13½ft. from each inside line. Be careful to check all the measurements before marking out the court, and make certain that all the angles are right angles. If space permits arrange for the court to run north and south, rather than east to west; a great deal of tennis is played in the afternoon and evening, and those who have to play facing westward are at a disadvantage because they will have to play with the sun shining in their eyes—provided there is any sunshine.

FLOWER BEDS IN SUMMER.—A. W., Lenton.—I have five beds, in grass, running parallel with a gravel path, and I wish them to be as varied and attractive as possible during the coming summer. There is an abundance of greenery, such as rhododendrons, near at hand to form a suitable background, therefore, I should like brilliant and striking plants in the beds. The central and two outer beds are oblong, while the intermediate beds are circular. The beds are 7ft. by 4ft. I do not want the beds to be paired, but would rather have each one filled differently, and have each one filled with a mass of one colour with a suitable edging. If you can assist me by suggesting suitable subjects for filling these beds, I shall be very greatly obliged.—Fill the central bed with Paul Crampel pelargonium, and provide an edging of Mr. Pollock or other good golden tricolor pelargonium, kept dwarf. In one of the outer beds place orange or orange and yellow tuberous begonias, and use the variegated Cocksfoot grass as an edging. At the other end use pink and rose or pink and white begonias, and edge with light-blue lobelias. In the circular beds plant tall fuchsias, keeping blue corollas next the pink begonias, and red ones at the other end. Plant these thinly, with a few bushy examples of the old golden-leaved Wave of Life around them, and a carpeting of the white Alyssum maritimum over the whole bed. A standard fuchsia, a standard heliotrope, or a Streptosolen Jamesoni, rising from the centre of a mass of the double white Marguerite Mrs. Sander, would provide an alternative filling for the circular beds.

NAMES OF PLANTS.

C. M., Earl's Colne.—1, Begonia Haageana; 2, Eupatorium ianthinum; 3, Cyrtomium falcatum; 4, probably a Cystopteris, send again a little later; 5, a form of Anemone fulgens.

NEWS FROM HEADQUARTERS.

BEGONIAS.

In every garden there is sure to be some particular spot which appeals to the owner more strongly than any other part.

It may be a bed in the centre of the lawn, which is in full view from your dressing-room, or the border outside the window of the room you frequent most during hot summer afternoons. The planting of these favourite sites, which you desire shall look bright and fresh from early summer until late autumn, often proves a serious problem, especially should one wish to break away from the stereotype Geranium, Calceolaria, and Lobelia.

An ideal plant for such positions is the Begonia, either in separate colours or carefully blended to suit individual tastes. A beautiful and lasting display can be easily obtained at a very low cost, the cultivation being particularly simple. Carters bedding Begonias have been specially selected for this purpose, and only bright colours and pleasing shades are contained in our mixtures, whilst the delightful separate colours meet with universal approval.

Where a brilliant effect is desired, bright scarlet, crimson, or yellow may be used, pink, copper, rose, and white being suitable for subdued effects. Write for our Spring Bulb Catalogue, which gives prices and full cultural directions. We shall also be pleased to suggest colour schemes and bedding effects, or give you any other information you may require.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Procession of the Flowers.

In another part of the present issue we have been able to show that within a comparatively short period such immense advances have been made in the more important classes of plants that belong to the herbaceous border as to very greatly increase their utility in giving beauty and interest to the flower garden. There have been improvements in the constitution and habit of many plants, there has been an increase in flower production, and an extension in the range of colouring in the majority of the several sections. In some cases there has, in addition, been a marked improvement in the quality of the individual blooms, both as regards form and substance, and if in the case of plants grown for the production of colour effects in the garden form is a quite secondary matter, it assuredly is no detriment, provided the formality is not such as to suggest heaviness when the flowers are seen from a short distance. With a full acquaintance with what has been accomplished since the restoration of hardy plants to public favour, and with a knowledge of the work that is now in progress, we feel it quite impossible to regard finality in the development of hardy plants as being within a measurable distance. On the other hand, there appears ample justification for anticipating that in the near future there will be advances equal to those which have already been made, and that some will be from directions which the most observant may not expect. Already the raisers have in the course of their activities shown that they fully appreciate the desirability of extending, as far as may be practicable, the flowering season of the chief kinds, and have also made some progress along this path which is full of promise. In answering to the call of the garden, we find in the flower-bedecked beds and borders assigned to hardy plants much to attract, and not a little that is of interest. We are, for example, reminded that, as a consequence of the additions that have within recent years been made to the irises, it is possible, given favourable weather, to have a procession of these exquisitely beautiful flowers from quite early in the year until July, when the elegant Siberian iris and the magnificent forms of Kæmpfer's iris contribute with prodigal liberality to the charms of the bog garden and waterside. Much also has been accomplished in the lengthening of the season of daffodils. This has been chiefly due to the introduction of varieties flowering somewhat earlier than those of older date; and evidently the raisers, as they enjoyed the charms of their favourite flowers, felt as did Herrick

MR. A. R. ALLAN.

when he sung, more than three centuries ago:

> "Faire daffodils, we weep to see
> You haste away so soone";

and then resolved to do their best to extend the season of these delightful flowers in another direction. Whatever may have been their feelings in this matter, some of the leaders in this interesting work turned their attention to the breeding of narcissi for late flowering. Hence it is the daffodil season covers a wider period than it used to do, and, indeed, wider than is at the present time apparent; for not until the newer varieties have been freely distributed will it be possible to fully appreciate the work that has been done in this direction. In referring to the daffodils, we are reminded of the herbaceous pæonies, for they are frequently grown in association for the purpose of extending the attractiveness of the beds and border over as long a period as possble. As we call to mind the glorious displays of colour produced by these stately flowers in gardens where they are largely grown, we feel that it would be an immense advantage if the season of flowering of the Chinese varieties could be extended into May. It would probably be a long and somewhat tedious task to obtain, by selective culture, an early-flowering race with flowers that by reason of their large size and fine form would make a strong appeal to cultivators; but the matter is well deserving of consideration. Progress has been made in the development of forms of Pæonia officinalis, which has long had a place in British gardens; and these might be planted rather more freely in spacious borders than has yet been considered desirable, because of the touch of colour they give to the garden in May. Not only has the season of the various classes of flowers been lengthened, but the season of flower production in the border, as a whole, has been extended considerably within recent years. More especially have the attractions of the herbaceous border been increased from the end of the summer onward by the introduction of large numbers of chrysanthemums, that bloom during September and October, and of Michaelmas daisies that yield of their flowers from August until quite late in the autumn. Until within a recent period the early-flowering chrysanthemums were by many regarded as belonging to the florists' flowers rather than to hardy plants, but now they are generally recognised as invaluable for giving colour and brightness to the mixed border during the greater part of the autumn, the period of effectiveness being determined by the character of the weather. The Michaelmas daisies are hardly less valuable, for they assist in maintaining the procession of flowers after the glory of the chrysanthemums has departed, and the number of really first-class varieties has been so largely increased as to enhance their usefulness a hundredfold, and afford another proof of the judgment and enterprise of those who are specially interested in hardy flowers.

Mr. A. R. Allan, head gardener to Lord and Lady Hillingdon, at Hillingdon

Court, Uxbridge, is the son of Mr. Allan, who has so long and ably managed the gardens at Gunton Park, Norwich. Mr. A. R. Allan had, therefore, the advantage of first-rate tuition at the beginning of his career, and subsequenly added to his experience in several of the most famous gardens in England. He has done excellent work at Hillingdon, and our pages have portrayed the roses, water lilies, summer bedding, and other features of the gardens he has charge of. Needless to say, with such an enthusiast in roses as Lady Hillingdon, these flowers are extensively and finely cultivated. But Mr. A. R. Allan is in no sense a specialist, but whatever he takes in hand he does well. At Hillingdon Court he has carried out a scheme of planting in which deciduous and evergreen trees and shrubs with brightly-coloured leaves have a large place. Borders of flowers of one colour are a feature, especially the red and the blue borders, and this at once indicates the extensive cultivation of herbaceous and annual plants. Spring-flowering bulbs in the grass are very beautiful at Hillingdon Court, and fine varieties of daffodils have been planted in this way with excellent effect. Both indoor and outdoor carnations occupy considerable space, and are capitally managed. Few have been so successful as Mr. A. R. Allan in the cultivation of the semi-tuberous winter-flowering begonias, and for exhibits of these in 1910 he has gained Silver-gilt Flora and Silver-gilt Banksian Medals at Westminster. He has also gained medals at the Royal Horticultural Hall for nymphæas, hardy fruits (Hogg Medal), Malmaison and border carnations, pears, strawberries in April, Darwin tulips, Zygopetalum Mackayi, and Lachenalia Nelsoni. Mr. A. R. Allan is a member of the R.H.S. Fruit and Vegetable Committee, and is a very energetic member of the governing body of the Gardeners' Orphan Fund.

Amenities of Kew Gardens.—For some time past the Richmond Corporation has been busily engaged with town planning schemes that have been prepared with a view to the preservation of the amenities of the town. The famous view from Richmond Hill has been already secured, and the scheme now in hand includes a long stretch of land on the Middlesex side of the Thames, and for some distance opposite to the Royal Botanic Gardens, Kew. An inquiry relating to this scheme was held at Richmond by the Local Government Board on the 19th inst., when a statement in support of the proposals was made by Sir David Prain, director of the Royal Gardens. In the course of the statement it was pointed out that the Royal Botanic Gardens is a scientific and technical institution, maintained for the promotion of botanical study and the increase of botanical knowledge. In order to fulfil the objects of the institution, a garden is required. Since there must be a garden attached to the institution in order that its scientific objects may be attained, advantage has been taken of this fact to utilise the garden as a means of fulfilling its technical object. To this end the garden is employed to illustrate practically the methods and principles of landscape gardening. One of the principles underlying the art and craft of landscape gardening is that, in the treatment of an area, account must be taken of its surroundings. In doing so, undesirable features have to be screened from view, while desirable features may be utilised in adding to the amenity of the area under control. The æsthetic value of Kew as at present laid out depends, in Sir David Prain's opinion, very largely upon the existence of open spaces beyond the Thames on the Middlesex side, and if the natural and unchecked consequences of modern industrial conditions lead to the conversion of these open spaces into a continuation of the less pleasing features that mark the corresponding tract of land to which Brentford is at present limited, then the necessity will arise for screening in, instead of utilising the spaces which at present so largely increase the amenities of Kew. It was also stated that the conditions over against Brentford, with its smoke, are unfavourable to plant life, as compared with those that prevail at the Richmond end of the gardens. Also that if these conditions extend along the river throughout the full extent of the garden boundary, the necessity will probably arise for the transfer to some other site of the institution as a whole.

The Literature of the Rose is both extensive and entertaining. Some of the older works are very beautiful, rare, and expensive, and the same may be said of some modern books dealing with the Queen of Flowers. Some idea of the vastness and interest of the literature of the rose will be forthcoming on April 1, when Mr. Arthur W. Paul, of Waltham Cross, will deliver a lecture on this subject at the meeting of the Royal Horticultural Society. Mr. A. W. Paul has an unusually fine horticultural library, and, naturally, has specialised in rose literature, consequently no one is better able to lecture upon it. His lecture will be illustrated by lantern views, and should attract a large audience.

Birmingham Botanical Gardens.—The beautiful gardens at Edgbaston, Birmingham, attract more people than formerly. In addition to the horticultural faetures there is now the added attraction of a small and interesting collection of animals, reptiles, and birds. Considerable expense has been incurred of late by the repair of the large range of glass-houses, reconstruction of bandstand and refreshment pavilion, and the increase of space and new flooring at the lower end of the exhibition hall. An increase of subscribers and a considerable advance of income from admissions have not, however, met the expenditure on renewals and construction, and there is now an accrued deficit of £1,500. Fortunately no less than £1,130 of this amount has already been subscribed by the committee and their friends, and an appeal has been made for the balance, so that the financial position of the institution may be made quite sound. It is anticipated that if the deficit is cleared off future annual expenditure may be kept within the limits of income.

The Easter Holidays.—The earliness of Easter this year suggested possibilities of bad weather for the holidays, and these were fulfilled, because, for the most part, the weather was gloomy and cold, with a rain and thunderstorm over London on the Saturday afternoon, and a terrific wind-storm in the evening and night of that day. So strong was the wind that great damage was done in various parts of the country, a notable item being the destruction of the pier at Worthing. Many seaside resorts suffered badly from wind and sea, while inland large numbers of fine old trees succumbed to the fury of the gale. In spite of a northerly wind and a temperature of about 46 degrees, large numbers of people visited the parks and open spaces in the London district on Bank Holiday, but the numbers were small as compared with a fine Easter. For instance, at Kew there were 62,000 visitors, as against 127,000 on Easter Monday of 1912. The closing of the apartments at Hampton Court and Windsor reduced the visitors there, and the Zoological Gardens did not attract as many people as usual. On the other hand, the British Museum, Natural History Museum, Victoria and Albert Museum, were all visited more freely than usual. At the Natural History Museum 13,904 visitors were recorded.

Horticultural Club.—There will be a house dinner of the Horticultural Club, at the Hotel Windsor, Victoria Street, Westminster, on Tuesday, April 1, at 6.30 p.m., to be followed by a lecture, entitled "Some Nature Notes in South Africa," by Mr. J. Edmund Clark. The lecture will be illustrated by lantern slides, prepared from photographs taken in South Africa by the lecturer.

Preservation of North London Views.—The Home Office has sanctioned the enforcement of bye-laws for the preservation of the beauty spots in the Enfield district from disfigurement by advertisements. From now onward no advertisement of any kind may be erected so as to be visible from Albany Park, Bush Hill Park Pleasure Grounds, Chase Green, Durants Park, Enfield Town Park, Hilly Fields, and North Enfield Recreation Ground, and no illuminated advertisement near these open spaces may exceed a height of 20ft. Further, provision is made to prevent the display of advertisements in such a way as to disfigure the natural beauty of the views to Northaw, Cuffley, Goff's Oak, Epping Forest, Winchmore Hill, Trent Park, Beech Hill Park, and The Ridgway. These bye-laws, which will be enforced by the Metropolitan Police and the officers of the Enfield Urban District Council, secure practically every park, open space, view, and vista in the district from disfigurement by advertisements.

Royal Gardeners' Orphan Fund.—We are officially informed that Col. the Right Hon. Mark Lockwood, C.V.O., M.P., has kindly consented to preside at the 25th annual dinner of this excellent charity, which is to take place at the Hotel Cecil on Thursday, May 15.

Co-operation at Pershore.—Co-operation in the matter of grading and selling has proved highly successful, as practised by the fruit growers and market gardeners in the Pershore district, so much so, indeed, that the Board of Agriculture is taking a keen interest in the undertaking. The co-operators handled 107,892 packages in 1912, and sales amounted to £14,816, as against £10,799 in 1911. A bonus has been given to the employees, and the shareholders have benefited in similar fashion according to the value of the produce sent for sale. After allowing for depreciation a substantial profit remains, and this is all in addition to the extra advantages resulting from prompt sales and distribution.

Daffodils and Easter.—As in previous years, the Lincolnshire growers of daffodils for the production of flowers for market were able, during the week preceding Easter Day, to send large consignments to London and the principal provincial towns, but the supplies were considerably below the average. In some instances this falling off in the quantities of flowers marketed has been attributed to the inclemency of the weather that had been experienced. The weather may have had some effect in bringing about a shortage, but the cause of the deficiency has been the early date on which Easter has fallen this year. Easter Day

may fall upon any date between March 22 and April 25, and consequently this year it fell upon the earliest possible date, or a fortnight earlier than in 1912. During the second and third weeks of April there is usually an abundance of daffodils, as was the case last year, and owing to the large demand for flowers for church decoration, they invariably command a remunerative price.

Colchester Challenge Cup for Roses.—Mrs. Egerton-Green has presented a challenge cup of the value of 40 guineas to the Colchester Horticultural Society. The cup will be known as "The Claude Egerton-Green Challenge Plate," and is intended to commemorate the interest taken by the late Mr. Egerton-Green in the society and its work.

A Profitable Workhouse Garden.—At a recent meeting of the Cardiff Board of Guardians it was stated that four acres of land, close to the Ely Workhouse, had been cultivated by the Master, Mr. Moore, solely with the labour of the workhouse inmates, with the result that the year's working showed a profit of £200.

The Floral Parade of Honolulu was held on February 22 last and is described by the "Sunday Advertiser" of that city as the most successful of the parades that have been held in the capital of Hawaii since their institution eight years ago. From the starting of the first floral car at 2 p.m. until 4.30 p.m., the procession of cars was continuous, and although the decorations varied in merit, all the cars were more or less attractive. Judging from the large number of illustrations published by the "Sunday Advertiser," some of them must have evinced much taste on the part of those who had carried out the floral arrangements. It appears that the cars decorated with the silver sword plant and with cherry bloom were the most beautiful of the many cars that had a place in the procession. This latter was provided by Japanese residents, and was in the true style of their native land. Of the other cars one was decorated with brilliantly-coloured poinsettias, another with golden and red crotons, a third with bougainvilleas, a fourth with chrysanthemums, a fifth with roses, a sixth with carnations, a seventh with pineapples, and so on. The decorations were not only attractive, but they were of interest as evidence of the manner in which the flowers that belong to the spring, summer, and autumn may, in this tropical region, be seen in association at the beginning of the first of the three seasons.

Norwich Spring Show.—Owing to the earliness of the season the committee of the Norfolk and Norwich Society caused inquiries to be made amongst exhibitors as to the best date for the spring show, with the result that they now announce it for Thursday, April 17, instead of the 24th, as at first fixed.

Lime-sulphur Wash for American Gooseberry Mildew.—During the season of 1912 experiments were carried out, under the direction of Mr. E. S. Salmon, F.L.S., the mycologist of the South-Eastern Agricultural College, Wye, for the purpose of ascertaining at what strength (specific gravity) lime-sulphur wash can be used on the foliage of the gooseberry without causing injury. The varieties selected for experiment were Warrington, Valentine's Seedling, Whinham's Industry, Lancashire Lad, Berry's Early, Crown Bob, Rifleman, Yellow Rough, and May Duke, the experiments being carried out on certain fruit farms in the Swanley district. A full report on the results appears in the current issue of the "Journal" of the Board of Agriculture, and the conclusions arrived at are as follows: Different varieties of gooseberries differ to a marked degree as regards the susceptibility of the foliage to injury from the lime-sulphur wash. It is possible with some varieties, e.g., May Duke, to spray repeatedly throughout the season with lime-sulphur, at a strength (1.01 sp. gr.) sufficient to prevent the attacks of American gooseberry mildew, without causing any injury to the foliage. Under ordinary summer weather conditions the "strength" of the lime-sulphur wash should be as follows: For Whinham's Industry, Rifleman, Warrington, and May Duke: 1.01 sp. gr. Lancashire Lad: 1.005 sp. gr. Crown Bob. 1.005 sp. gr. early in the season; later in the season some injury may be caused. Berry's Early: 1.005 sp. gr. early in the season, and when the bushes are more or less shaded; later in the season injury is caused by the wash at this, and at lower, concentration. Valentine's Seedling and Yellow Rough show so marked a susceptibility to injury that they cannot safely be sprayed with lime-sulphur. For the present—until further experiments have been carried out—the "half-strength" wash (1.005 sp. gr.) should be used (except where indicated above), and the spraying done on an experimental scale.

NEW ALPINE PLANTS.

The increasing favour shown to rock gardening has given encouragement to introducers of new alpine flowers, and the past year has witnessed the introduction of a number of plants of real novelty, together with the recall of some which had gone out of cultivation. In the present notes a few of the latter will appear, as these are practically new, and generally worthy of the notice of purchasers.

Anemone pulsatilla rosea Mrs. Van der Elst, from the Royal Tottenham Nurseries, Holland, is a lovely rose-coloured Pasque flower, and well worthy the Award of Merit from the National Hardy Plant Society.

[Photo: Bees, Lim., Liverpool.

CODONOPSIS MELEAGRIS.

A distinct species; the flowers porcelaine blue with chocolate-coloured reticulations. Introduced by Messrs. Bees, Lim.

A few dwarf species of asters have been brought forward. Among these are the following: Aster brachytrichus (Bees, Lim.), a Chinese species, little more than nine inches high, with narrow leaves and narrow light lilac ray florets. A. Purdomi (J. Veitch and Sons) is another Chinese species, about six inches high. The flowers are pale violet. A. yunnanensis atroviridis (Bees, Lim.) is superior to A. brachytrichus, is about nine inches high, and has broad, light blue florets.

Astilbe simplicifolia is a capital novelty (G. Reuthe), and well deserved its Award of Merit from the R.H.S. It is six inches high, and has a graceful habit and white

flowers. Keeley's variety of Cheiranthus mutabilis, about nine inches high, has flowers varying from almost mahogany-brown to crimson and purple on the same truss.

Codonopsis meleagris (Bees, Lim.) is one of the best, though not the most striking of new flowers. It grows to a height of about nine inches; rather less on a dry rockery. The flowers are of a light porcelain blue, netted chocolate. It is good for the higher parts of the rockery.

Cotoneaster divaricata, shown from Aldenham House, is one of the few new Chinese shrubs for the rock garden. It is of low growth, and has plenty of red berries. Its value is attested by the First Class Certificate it secured from the R.H.S.

Crocus chrysanthus E. A. Bowles, so well shown by Messrs. Barr and Sons, a short time since, is a beautiful early yellow crocus for the rock garden. It was sent out by Mr. G. C. van Tubergen, jun. Few dwarf dracocephalums have appeared lately, so that D. bullatum, resembling D. grandiflorum, but purple instead of blue (Bees, Lim.), will be appreciated; it is easier to grow than the older species, and is of trailing habit. Ephedra Garrardiana (Bees, Lim.) will only be suitable for dry walls or rockeries. It is a rush-like plant with scarlet flowers in the axils, and flowers late. About a dozen new varieties of Erica carnea were distributed in the autumn by Messrs. J. Backhouse and Son. They were selected by Mr. Richard Potter, and, though some are much alike, there is sufficient variety to please lovers of this winter-flowering heath. Fostera Bidwilli (Bees, Lim.) I have not seen in bloom, nor can I find any record of its flowers. It has felt-like white tomentum on the leaves. Helichrysum frigidum is not a novelty, but has been brought into prominence again. It is a dwarf white-flowered silvery plant.

Lewisia Howelli (M. Prichard) is not new, but is really good. It will possibly be short-lived, save in dry places, and will suit the moraine. It is creamy-apricot and rose. Lithospermum Frœbeli (M. Pritchard), from the same nursery, is a good trailer, with deep blue flowers; and shown from the same quarter has been the golden-yellow Lysimachia Henryi, a good prostrate plant.

Mazus rugosus (Wargrave Hardy Plant Farm), figured in the Gardeners' Magazine of March 8, 1913, is a splendid acquisition, with low, creeping growth, and lovely violet flowers. As shown, it appears distinct from the annual M. hornemannia, with which it is said to be synonymus. Oxytropis yunnanensis (Bees, Lim.), a tufted blue-flowered plant, will appeal to some; while the low-growing Omphalodes cornifolia, shown in London last summer, is another blue-flowered plant worthy of notice.

Oxalis adenophylla, a Chilean species, was shown by Mr. H. J. Elwes last year, and is practically new, though in cultivation for a year or two. It is superior even to O. enneaphylla, and has pale pink flowers with a blue line down the centre. At the same show (the Royal International) Mr. Clarence Elliot exhibited O. enneaphylla rosea, a pleasing rose form of a favourite plant. Patrinia palmata (Miss Willmott) figured in the Gardeners' Magazine of July 7, 1912, is a yellow-flowered hardy plant only a few inches high. It is hardy with the writer in the moraine.

New primulas can only be briefly referred to, so numerous are they. P. Winteri (R. Gill), of 1911, has come well to the front; and now P. Knuthiana (J. Veitch and Sons), about four inches high, after the style of capitata, and blue, with P. Juliæ, from the Oxford Botanic Gardens, have become popular. The latter is rosy-lilac. P. Warleyensis (Miss Willmott) is of doubtful hardiness. It is two and a-half inches high, and is rosy-lilac. P. angustidens, purple-violet, after the style of Poissoni; P. farinosa Beesi, rosy-pink; and P. secundiflora and P. pulchelloides, the two last of the sikkimensis character in colour and habit, emanate from Messrs. Bees, Lim. A number of other Chinese primulas, such as P. yunnansis and P. membranifolia, have been exhibited before committees of the R.H.S., but have not yet been sent out. P. pulverulenta Mrs. Berkeley (J. Veitch and Sons) white, was much admired at the Chelsea exhibition. Romanzoffia Suksdorfi, white, is a saxifraga-like plant.

Quite a crowd of new varieties of saxifrages have appeared, as well as some good species. Mrs. Lloyd Edwards' hybrids, Comet and Mrs. J. F. Tottenham, both white, are very fine. S. burseriana elegans rosea, rose: S. Aizoon Rex, and S. Primrose Bee, yellow, may be named specially, and of the crowd of new red mossy and silver saxifrages it may be said that they are legion.

Silene Hookeri, a lovely plant, though not new, caused a sensation at Chelsea. It is a handsome alpine, with rose-pink flowers. Tanacetum adenanthum, about ten inches high, yellow, with silvery leaves, promises well; as also does Veronica pirolæformis (Bees, Lim.), another lovely Chinese plant, about five inches high, and porcelain blue. Viburnum Davidi (Veitch), white, is a promising hardy shrub for the rockery.

In Wahlenbergia vincæflora, shown also as W. gentianoides, we have a lovely pale blue plant, not new, but hardly ever seen. Though about eighteen inches high, it is excellent for the large rock garden. If the Mexican Weldenia candida, which was one of the plants with which Messrs. Bees won the Farrer Cup for alpines, proves hardy, it will be keenly sought after. It forms a rosette of pretty leaves, above which are the lovely white crocus-like flowers.

Such are some of the best of the novelties or reintroduced plants which have appeared within the last twelve months or so.

S. Arnott.

[Photo: Bees, Lim., Liverpool.

OXALIS ADENOPHYLLA.

A Chilian species with pale pink flowers. From a photograph of a plant grown by Messrs. Bees, Lim.

EXCESSIVE USE OF STIMULATING MANURES.

We hear a great deal about the deterioration of many classes of garden plants, and of varieties quickly wearing out. Added to this, new diseases continually crop up, and prove a source of worry to the gardener. There is no gainsaying the fact that highly stimulating manures are now used to a far greater extent than they ever were before, and the question arises whether this excessive manuring is not the cause of a good deal of the trouble. I am inclined to think that it is, for, in the case of many diseased plants a return to more rational diet will serve to restore them to health. Take ivy-leaved pelargoniums, for instance; some varieties, at least, are very subject to a blotchy disease of leaf and stem (gouty eczema, if you will) which arrests both growth and flower development. Highly-fed plants are far more liable to this than any others, and even when badly affected they will, if potted or planted in some good sweet soil, without manure, gradually grow out of it. Experience has led most cultivators to discontinue the propagation of chrysanthemums from highly-fed plants, as their constitution is so much weakened by the stimulants employed. It seems to me a parallel case to a man kept up by spirits to go through some great ordeal, which he may accomplish successfully, but after the excitement has worn off he is physically a far worse man than he was before. A plant such as a cucumber, which simply plays a part and then dies, may be liberally fed, although an excess may influence the seed, but to keep a plant in permanent health my advice would be—use stimulating manures with a niggardly hand.

W.

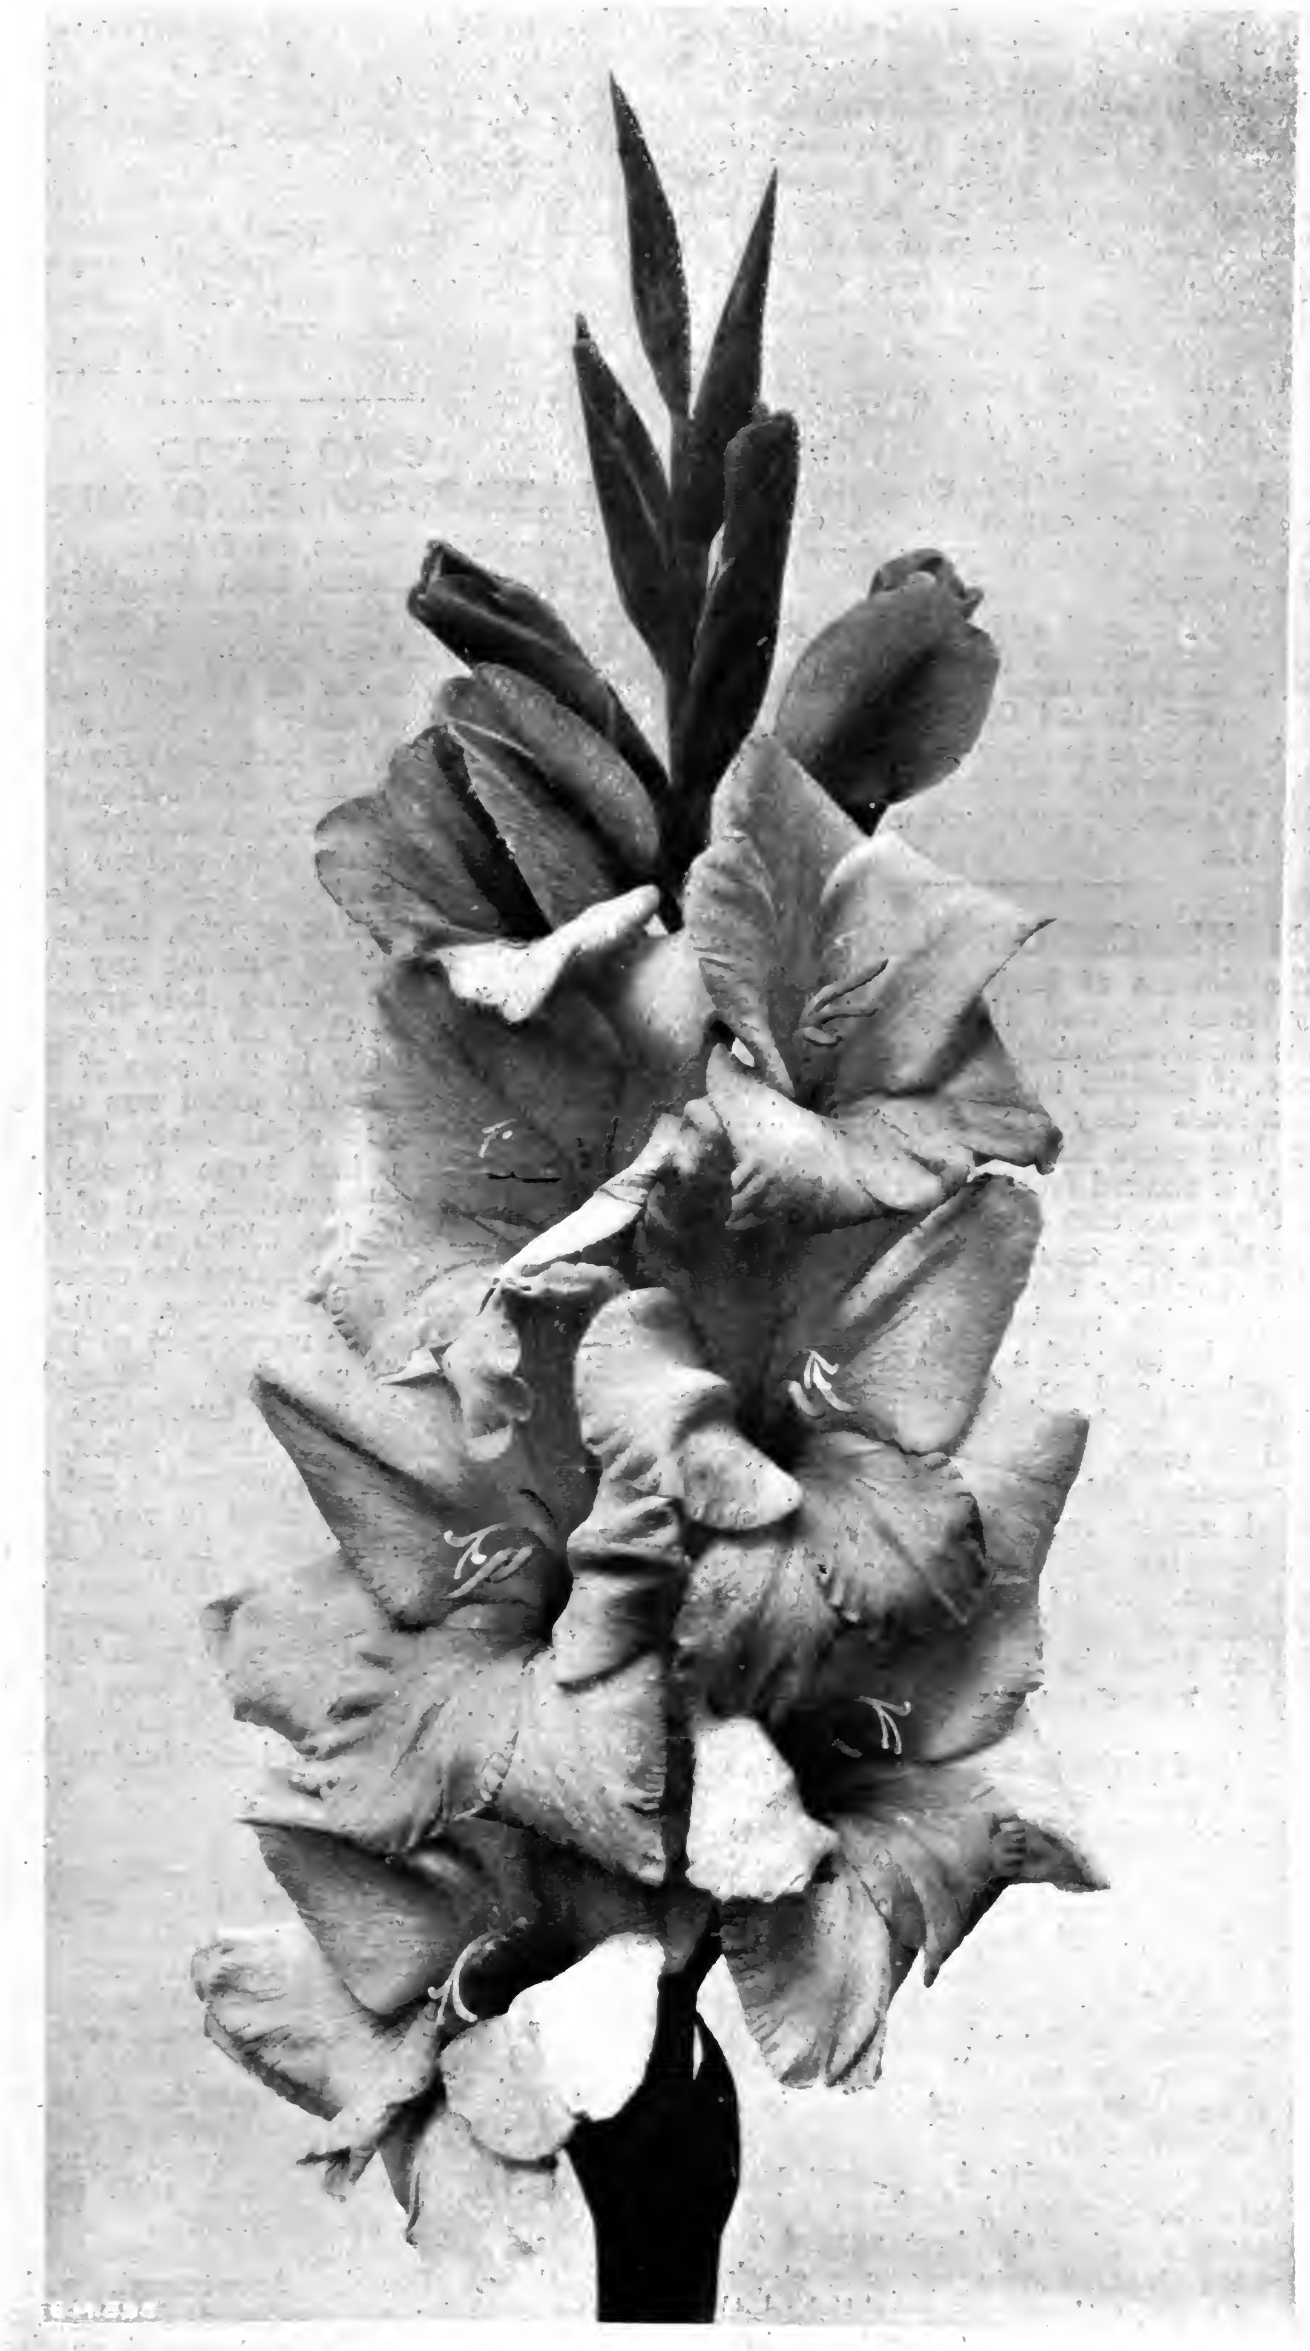
ADVANCES IN GLADIOLI.

The Iridea—the Order of the Flag—is very rich in good garden plants, and of special interest because so many of its genera have been taken in hand by raisers, to the very great improvement of our gardens. One has only to mention such families as the iris, crocus, and gladiolus to show how valuable the Flag order is horticulturally.

Dean Herbert, who was such a keen hybridist, had large numbers of hybrid gladioli at Spofforth prior to 1836, "with every shade of colour from white to scarlet, rose, peppery, and blackish-purple, and some are exquisitely speckled in consequence of the cross with tristis." Curiously enough however, the good Dean considered it was not "by crossing different species or local varieties of plants only that the cultivator may add to the beauty of his collection. Much may be done undoubtedly by crossing judiciously the finest seminal varieties of such plants as have been already improved in our gardens, and are disposed to break into a multiplicity of forms and colours." Unquestionably, this method has been the means by which our gardens have been greatly enriched by gladioli, but for the production of new races a species or a hybrid has been necessary in combination with garden forms of a good type.

For instance, the Childsi group, which comprises strong growers with large blooms, was raised by the late Herr Max Leichtlin, in 1882, by crossing selected varieties of the Gandavensis group with the crimson, light-spotted G. Saundersi. The Ghent gladiolus, G. gandavensis, is a very mixed race, though it was originated by crossing G. psittacinus and G. cardinalis. G. blandus, G. oppositifolius, and G. ramosus have also been used, probably in the earlier years of the race, to improve it, and add variety of colouring. In 1857 Mr. Kelway commenced work upon this group, and now most gardens show some evidences of the splendid results of his labours, and that of his successors. From white to maroon, from pink to purple, and salmon to orange, the whole gamut of colour shading and marking seems to have been laid under contribution in these stately flowers. Fully as robust, and giving an even wider colour range than G. gandavensis, is the race known as G. Kelwayi, evolved from it, by various intercrossings, by the Messrs. Kelway. In these varieties the colour combinations are striking and beautiful, the flowers large, well expanded, and finely set on remarkably handsome spikes. Latterly the production of fawn and yellow varieties has received special attention, and, for the moment, the acme of perfection in this direction has been reached by Golden Measure, a variety that was the great centre of attraction at the meeting of the National Gladiolus Society in 1912, when it gained for the Langport firm the silver cup as the best yellow variety in commerce. This is a superb, clear bright yellow gladiolus, and one that all lovers of these flowers will desire, but, as in the case of a very distinct new daffodil, the price is a trifle prohibitive at present, i.e., ten guineas per bulb—but well worth it. Fortunately, for most of us, there are varieties that are very beautiful, but not quite the same shade of rich colour, at moderate rates.

M. Lemoine originated the G. Lemoinei race, which have broad flowers, characterised by large yellow blotches on a ground colour that ranges from creamy-white to blood-red. Here again the Messrs. Kelway have added their touch of improvement to a beautiful group that began with the crossing of G. purpureo-auratus with G. gandavensis. The G. nanceianus group has descended from G. Saundersi, and selected varieties of G. Lemoinei, and is more free-blooming than the true gandavensis forms, while it yields varieties with purple, claret, and violet colouring. It may be mentioned here that several gladioli have blue colouring, but the bluest of blue varieties is Baron Jules Hulot, of violet-blue shade, and a gladiolus that always fixes attention upon itself wherever grown or shown.



GLADIOLUS GOLDEN MEASURE.

The finest yellow gladiolus yet raised; it gained for Messrs. Kelway and Son the silver cup offered for the greatest advance in this colour by the National Gladiolus Society in 1912.

There are several other races, such as Colvillei, which gives us such charming plants for pot culture and early flowering, and the later set of Princeps hybrids, and the quite new family produced by crossing Kelwayi forms with the pollen of G. primulinus, the latter coming from near the Zambesi Falls.

Gladioli are not nearly enough grown, nor are they sufficiently well grown in many gardens. They love rich soil, and a fairly heavy one, if well drained, and though they provide splendid colouring in a mixed border, they too often have to compete there with strong-growing and voracious herbaceous subjects. If every lover of the genus would plant a few dozen of the better varieties in a plot of land deeply worked and freely manured the previous autumn, or on soil heavily manured for a previous crop, the capacity of the plants to produce fine secondary spikes would be better appreciated. The old practice of placing some sand just under and just over each corm at planting time has much to recommend it, especially in retentive soils. Gladioli are sunshine lovers, but when grown for exhibition it is necessary to shade the lower part of the spike, so that the first-opened flowers may remain fresh until many of the upper ones have expanded. A carpeting plant of some kind is generally advisable under gladioli.

"And the small wild Pinks from tender
Feather-grasses peep at us;
While above them burns on slender
Stems the red Gladiolus."

We should have to alter these lines of Lord Lytton's, however, to make them fitly describe the robust, many-coloured gladioli of our times. C. K.

HERBACEOUS PÆONIES.

The flowers of herbaceous pæonies not only make a grand display in the herbaceous borders during the summer months, where, if planted in bold groups of separate colours they are very attractive, as they last some time in perfection, particularly if shaded from the bright sunshine, but they are also useful for cutting for decorative purposes.

Unfortunately these pæonies have large foliage, which renders it necessary for them to be planted a good distance apart to develop, and so, when grown in the herbaceous borders, after the flowering period is over, there is always a blank. To overcome this the roots ought to be allowed ample room to admit of some later-flowering subjects being planted between them. When grown specially for the production of cut flowers it is preferable to plant them in a plot by themselves, where they can be liberally treated while growing.

Pæonies delight in a deep rich loam, and an abundance of moisture at the roots while growing, therefore it is best to plant them by themselves, where, during dry weather, they can be mulched and liberally watered. If left for several years they throw up strong flower stems, which, in many instances, are from two to three feet long, carrying three or four blooms each. As these flowers do not all expand at the same time their season of bloom is prolonged considerably.

There is no difficulty in raising a stock of plants from seeds, but those who are desirous of growing the best named varieties would do well to procure a stock of roots, and when these are established they may be increased by root cuttings, in the same way as seakale and many other plants. The cuttings take some time to callus, therefore the plants will be small the first season, but when they have once formed crowns they grow away rapidly. Care will be needed with the cuttings until new roots are formed, as they are liable to rot if the soil is too wet. Though pæonies may be planted at any time during the winter, after the foliage has died down, I have always found plants grow away more vigorously if planted early in the autumn, before the crown buds are too prominent. If some of the tubers are taken off them and made into cuttings these will have made crowns by the following autumn, but it is well to allow them to remain in the nursery beds for another season to become thoroughly established.

There is now a long list of choice named varieties of pæonies, ranging from white to deep crimson, and not a few of them are very sweetly scented. I will just name a few for the guidance of those who may not have grown them: Albert Crousse, soft blush; Duke of Cornwall, bright crimson; Gloriosa, white, tipped with pink; La Perle, flesh colour; Snowball, pure white; Lutea plenissima, soft yellow; Beauty of Tokio, pure white, and very large.

H. C. Prinsep.

TWO GOOD LATE-FLOWERING LILIES.

The importations of Lilium nepalense and L. sulphureum, both delightful late-flowering lilies for the greenhouse, appear this year to be remarkably fine. Neither of them are, so far as I know, cultivated for the sake of their bulbs, the supply being kept up by importations from Upper Burmah, where they are collected in a wild state. A somewhat notable feature in connection with their culture is that after being potted and placed under conditions favourable to growth, the bulbs remain for some time without any signs of the young shoots making their appearance. When, however, they do start progress is rapid, particularly in the case of L. sulphureum, which will often run up to a height of six to eight feet. This last-named species has large funnel-shaped flowers, rich yellow within, and of a paler tone on the exterior, which is flushed with reddish-brown. The leaves are exceedingly numerous, and rather narrow, while in the axils thereof on the upper part of the stem bulbils are freely produced. These bulbils are large, and, under favourable conditions, will flower in three years. The other species—L. nepalense—is not so tall a grower, and the stem is very slender. The flowers, which reflex in a Turk's cap-like fashion, but not to the same extent, have the basal portion of the segments deep purple, and the upper part greenish-yellow or yellowish-green. In the tone of colour and the extent of the purple marking there is a certain amount of individual variation.

W. T.

Freesia Ragioneri.—This strain of freesias is, I believe, of Italian origin, and shows a more decided range in colour than we have hitherto been accustomed to see. True, ever since the introduction of Freesia Armstrongi (now a dozen years or so ago), coloured forms have been making their appearance, but in most cases the tints represented have been various shades of pink, rose, and lilac. In these new-comers bronzy tints occur, and there is also a wide range in pinks, orange, pale-blues, etc. All these varieties seem to have the rather attenuated growth of Freesia Armstrongi, and another, and by no means desirable, feature inherited from this last named species, is that they are to a great extent wanting in the delicious fragrance which constitutes one of the greatest charms of the popular Freesia refracta alba.—S. W.

CLARKIA ELEGANS.

It is not surprising that Clarkia elegans should gain in estimation with the years. It is a hardy annual that presents beauty and utility in the highest degree. It is probably in the open border that its elegant habit and warm, rich tones of colour appear to the best advantage, while its utility is also demonstrated by the fact that it succeeds as readily in pots as in the open border. The flowers are not ephemeral, and either upon the plants or in a cut state they retain their brightness and freshness for some considerable time.

Clarkias do not reach such early maturity as some others, nor is their flowering season of such brief duration. For the earliest display it is usual to sow in the open during autumn, transplanting the seedlings into pots or boxes, and wintering in a light, airy, and frost-proof structure. With increasing sunshine in spring, they are potted into larger sizes, and subsequently into their flowering pots, or planted in the open some time in March. In the case of pot-grown plants, these flower toward the end of April and during May, while the open ground plants flower during June and July. The earliest spring sowing should be made in boxes under glass, and the seedlings grown steadily in a cool structure, transplanting them into prepared soil, protected by handlights, and finally planting out in their flowering quarters during April. Where clarkias are wanted for a late summer display, the seeds should be sown during April where the plants are intended to flower. Thinning must be taken in hand early, and is best performed in two or three operations, with an interval of ten days between, allowing 15 to 18 inches between the plants at the final thinning. Staking should have early attention, for all the forms of Clarkia elegans attain a height of three feet in the open, and a light bamboo support prevents the plants from breaking down under the influence of rain or wind.

The most popular variety of Clarkia elegans is Salmon Queen, in which the double flowers are delightfully coloured salmon-rose; in Vesuvius the salmon shade is almost displaced by orange-scarlet; while in Orange King we have even a brighter selection; Brilliant is a variety with glowing rosy-salmon flowers; in Purple Prince the colour is a rich rose-purple; in White Queen the flowers are white, and Queen Mary is a lovely shade of rose-carmine, one of the loveliest shades in the whole group; Scarlet Queen is exceedingly brilliant in colour, and is an effective shade to employ for distant effect. Thomas Smith.

Coombe Court Gardens.

The Water Garden. — Located around most water gardens are steep banks and hillocks, and these invariably provide sites for numerous plants associated with water, such as bamboos, gunneras, astilbes, spiræas, and senecios. The fact must not be overlooked that such positions, although more or less near the water, sometimes become very dry during the summer, and, therefore, should at that season receive a heavy mulching of rotten cow manure, which greatly helps to retain moisture, as well as to produce luxuriant growth. I do not mean to infer that these subjects only require mulching when situated in such positions, as they at all times respond to such treatment. It also proves very beneficial to Iris Kæmpferi, if there has been any recent planting of this popular Japanese iris; the soil must be kept moist round the roots should we experience harsh drying winds. This more especially refers to imported roots recently planted.—T. B. Field.

PENTSTEMONS.

The varieties of pentstemons are very variable in character both in habit of growth and in their flowers. Some species only grow to a few inches in height and among these are some gems for the rock garden, such as Pentstemon glaber and P. humilis, while others form good bushes. Undoubtedly the best known and by far the most serviceable for furnishing display lasting over a period of several months are the hybrids.

The wide range of colour they provide, shading from white to scarlet, and from purple to lilac, bordering on blue and quite reaching a true blue, makes them very attractive, and whether planted en masse or separate shades in beds and borders or when blended they are alike effective. Their habit of growth again adds to their merit as desirable bedding plants, and with a little judicious management it is possible to produce any number of well-grown plants for bedding purposes with a minimum of trouble.

The usual method of raising plants are from cuttings or seeds. The former is the one most practised, as it is the only method of keeping a true stock of any particular colour or variety. Seedlings usually show much variation, but if raised from seeds which have been selected from a good stock they prove both interesting and useful when one contemplates planting for a mixed effect.

A feature in these cultivations which has an important bearing on their successful flowering from June onwards is to have good plants ready to put out at the end of March or early in April, and to obtain these it is essential that cuttings be put in early in September. Choose young shoots growing sturdily from the base of the old plants, and after preparing them as follows put them in a shallow frame containing a few inches of light sandy soil. If space is not limited allow about 3 inches each way between the cuttings so that will give sufficient room for the young plants to develop without having to disturb until planted out in the spring, otherwise put 4 inches apart; then water in, and keep the frame close and shaded from bright sun for a few weeks until the cuttings have taken root, afterwards they should be given all the sunshine except when the temperature falls to freezing point. The lights can be pulled back on all fine days when mild, as this will prevent the young plants from becoming drawn.

When raising stock from seeds sow in August and when the seedlings are large enough to handle pot them singly into small pots and treat in a similar manner to that advised for cuttings. Those sown now early in the new year, and placed in gentle heat to germinate, form good plants ready for planting out in May, but those in the ordinary way will not flower as early as the autumn raised plants.

Occasionally some little trouble is experienced with plants dying off in an inexplicable manner and somewhat spoiling the effect of the beds; this can be overcome by a frequent dressing of soot and also by a free liberal dressing of rank manure being dug into the ground when preparing it for receiving the plants. The very hard and stiff ones are objectionable, leaf and coarse ones are good should be given to make it friable and more suitable to their requirements. Be occasionally examining the plants during the flowering season, and pinching out the leading shoots as soon as the flowers are over, cause growths are induced to develop and blooms are more freely produced.

There are now many named varieties in commerce that are of quite exceptional merit. Of these the following may well be made a selection: Cerise Queen, Queen Victoria, Sutton's Scarlet, Pink Gem, Mrs. Sinkins, Purple Gem, Mrs. Kingsmill, Mrs. Holden, Mrs. Neal, Mrs. Watts, Marchioness of Tullibardine, Sir J. Shackleton, and Ware's Fire Dragon, for best groups in borders.

T. B. Field.

PENTSTEMON FIRE DRAGON

Flowers bright scarlet with white throat. A fine variety that has been raised by Messrs. T. S. Ware Ltd., Feltham.

SPIRÆAS AND ASTILBES.

The merest mention of spiræas and astilbes bring to mind summer-tide pictures of garden beauty, and one's thoughts are rapidly conveyed to the bog garden and the environs of the water garden, the places "par excellence" for the successful culture of these two distinct, beautiful, and easily-grown classes of plants.

Taking the spiræas first, I would urge upon all who have a sufficiency of garden space to cultivate S. gigantea and S. gigantea rosea. These are striking plants of noble appearance, often attaining a height ranging from eight to ten feet. The foliage is bold and effective, while the blossoms of the former are white, and rosea carries a pleasing pink colour. S. venusta, or lobata, is a very pretty rosy-hued species, tall and stately in growth, and of exceeding merit; it is essentially a species for all gardens. Several good varietal forms are in existence, and of these I may note Magnifica, with larger blossoms and richer colouring than the type; Blushing Bride, a pretty white, tinged with pink, and having showy red anthers; and Alba, pure white, the snowy heads being relieved by the rosy-hued anthers.

The Goat's-beard Spiræa, S. aruncus, is a bold, imposing plant, rather more fond of shade than the majority of spiræas. The variety S. Kneiffi is dwarfer, but in many ways is more beautiful. The elegant leafage is daintiness supreme, and with its mass of feathery, branching flower plumes it makes a most attractive subject for massing by the watersides.

The free-growing native S. Ulmaria is best represented by the fine snowy-white double form, known as flore pleno. This makes a bold group, but I do not advise the single form for garden planting. S. palmata produces an unsurpassed glow of rosy-red colouring. It is best planted in drifts by the sides of a stream, or in a selected spot in the bog garden. The pure white form of this, palmata alba, is first-rate for contrasting, though, of course, not so valuable as the more brilliant type. S. filipendula, and the double-flowered S. filipendula plena, give snowy drifts of white blossom above the pretty ferny foliage, but these can only be used where the superior height and vigour are not desired, but for a miniature water-side they are delightful.

Astilbes are even more popular than the spiræas, and are being largely planted for effect, a point worth noting by all intending planters. Big bold masses and really telling breadths of each variety are necessary if one is to gain the fullest effect. When established, and in full blossom, the beauty of the masses of dainty spires, in white, pink, and rose, with the rich greenery of the foliage as a setting, is almost indescribable.

Of astilbes there is practically no end. The arrival, a few seasons ago, of A. Davidi and A. grandis marked a new era for the genus. The deep rosy-red plumes of Davidi, and the white-flowered grandis, winning their way into popular favour, have opened the way for the new Arendsi hybrids, and Messrs. Lemoine's fine introductions. The coming of those splendid astilbes, Queen Alexandra, rose-pink, and Peach Blossom, also materially assisted in the work of popularising the genus.

Of the Arendsi group I may briefly commend Ceres, a pretty rosy-pink; Salmon Queen, a splendid tall salmon-pink of decided beauty; Pink Pearl, a soft pleasing pink; Venus, a deep pink, with almost a tone of purple in it; and Cream Pearl, a pretty creamy variety of pleasing appearance. There is much of the character of Davidi in many of these varieties, but all are worthy of the garden-lover's attention.

A few of the more notable of Messrs. Lemoine's introduction are, briefly, as follows: Carminea is a tall pleasing carmine variety, with just a touch of violet in its composition; Rubella, a bright rich rosy-pink, is a splendid plant, and produces a heavy crop of blossom; Rutilans, the "shining astilbe," is capable of exquisite effects, its rosy-carmine colouring being very appealing to the eye; Olympic gives tall spikes of soft rosy-pink, a pretty gem; Mousseline is a dainty, compact, rosy-lilac form; Gerbe de Neige is a grand pure white, of fine appearance, and has splendid spikes of blossom.

Of other astilbes, such as the varieties of A. rivularis, of which gigantea, a splendid erect creamy-white, and major, a large showy pure white, are about the best, and the extremely useful A. chinensis a sterling decorative subject, together with the varied forms of A. japonica, A. astilboides, etc. (a group which are often referred to as spiræas), are all of first-rate importance for the moist margins of the water garden.

P. S. Hayward.

ASTILBE RUBELLA.

A beautiful hybrid with bold spikes of pink flowers, as growing in the nurseries of Messrs. Wallace and Co., Colchester.

THE HARDY PLANT INDUSTRY.

As we recall to mind the many distinct, beautiful and rich colour effects which are produced by the hardy plants that have a place in well-arranged borders, as they pass in procession during the period between the opening days of the season of spring and the close of the autumn, we cannot but feel that few probably appreciate the importance of the industry which enables us to furnish our beds and borders at a minimum of expense and trouble with the most beautiful

A BOLD SWEEP OF HARDY HERBACEOUS PLANTS (DOWNSIDE, LEATHERHEAD).

plants from all parts of the world. The industry has been developed at a somewhat rapid rate, and those who are engaged in it have taken advantage of the opportunities the horticultural exhibitions afford for presenting their specialities to public notice, and thereby enabling visitors to become acquainted with the beauty and effectiveness of many kinds.

Lovers of hardy plants have not been startled by the introduction of new forms, commanding large sums on their introduction, but they have been fully satisfied by the steady flow of novelties, and they have expressed their satisfaction in such manner as to compel all the leaders of the industry to enlarge the sphere of their activities. It is now far too late to institute comparison between the hardy flowers now beautifying the flower garden and the showy tender plants that for a time occupied their place, although writers now and again suggest they are under the impression that in large numbers of gardens zonal pelargoniums, calceolarias, and similar subjects still predominate. A quarter of a century ago such reference would have been appropriate, but now we need only concern ourselves with the hardy plants, for they hold undisputed sway, and where it is not found desirable to wholly banish tender plants from the flower garden during the summer months the great superiority of the hardy kinds is fully recognised. This is as it should be, for their strong individuality in habit of growth, in the form of their flowers, and in the varied shades of colour, render them not less valuable for their absorbing interest than for effectiveness.

Hardy Plants in the Early Victorian Days.

In the early Victorian days the flower garden was in a rapid state of transition, as at that time there was a reaction in favour of greater brightness than that which had prevailed for some years previously. In the early part of the last century very close attention does not appear to have been given to the ornamental features of the garden that depended more or less upon flowering plants. There was considerable interest in flowers, but it was chiefly shared by the auriculas, carnations, pinks, polyanthuses, ranunculuses, tulips, and other florists' flowers, that were then grown in considerable numbers for exhibitions. For the embellishment of the flower garden the chief dependence was upon hardy annuals and perennials, and, according to the author of an important book published about the middle of the last century, ten out of twelve kinds of each class were worthless trash, being weedy in appearance and unattractive in colour.

At this period cultivators appear to have wholly failed to appreciate the importance of so grouping the several kinds as to produce distinct and tasteful colour effects. Hence beds and borders were singularly lacking in attractiveness. The endeavour on the part of the greater proportion of growers was to form collections of species and genera, rather than study the beauty of individuals, or the effect they were capable of producing. The formation of collections was not so pronounced in England as in Scotland, where a considerable number of gardens might have been found containing from 500 to 1,000 species and varieties. When the reaction set in against the dull and unattractive borders the change was effected with great rapidity, and, it should be added, with but little discrimination. Good and bad kinds were turned out of the borders without differentiation, and many hardy plants of great value in garden decoration were practically banished from cultivation. In the days anterior to the appearance of the brilliantly coloured Tom Thumb pelargonium above the horticultural horizon

considerable attention was paid to the more beautiful of the alpine plants then in cultivation, and the collections in some of the Scottish gardens were retained until after the massing of brilliantly-coloured tender plants in the flower garden had become general.

A BEAUTIFUL BORDER OF HERBACEOUS PLANTS (CARBERRY TOWERS).

Eclipse of Old-fashioned Border Flowers.

The eclipse of the old-fashioned hardy perennials was not total, but although in some of the old gardens in remote country districts the borders of perennials were defended from the inroads of the showy tender bedders, it came dangerously near thereto. If we turn to the periodic literature and the gardening books that were published about the middle of the last century, we find but little space given them. The hardy and tender plants to which the florists of that period were devoting their skill and care received a full share of attention in the various publications, but alpine and hardy border plants were given the scantiest of notice.

The opinion was held by a considerable proportion of the past generations of cultivators that hardy plants, when once planted, are so well able to take care of themselves as to require but little, if any, attention. As the result the borders in gardens wherein no attempt was made to form collections were, for the most part, given up to kinds of so strong a growth as to have been successful in the struggle for existence killing the major portion of those of moderate growth, and, it may be, possessing great beauty. This idea is still entertained by some owners of gardens, and given expression to by a few writers, and, as a consequence, we now and again meet with borders in which the plants present a weedy and otherwise unsatisfactory appearance. To obtain the full beauty and interest from a border that has been well furnished with hardy plants, there must be constant care, and the exercise of some skill. It is well this should be so, for were hardy plants independent of the cultural art much of the pleasure, and not a little of the interest associated with them would be lost. There are, however, no great difficulties in the cultivation of by far the greater proportion of the kinds, and flower lovers may plant them in their beds and borders with the assurance of achieving success of a high order.

Revival in Hardy Plants.

The commencement of the revival of interest in hardy plants takes us back about forty years, and a reference thereto recalls to mind many pleasant incidents in connection therewith. Possibly some of those who read these notes may consider that a later date would possibly be more correct. It must, however, be remembered that this revival, with its far-reaching effects, did not have its genesis coincident with the time when owners of gardens and those engaged in their management, began to buy and plant hardy perennials in considerable quantities. Such activities were a manifest proof that a great change was being made; but we have to go back some years anterior thereto for the purpose of finding the initiation of the work that rendered the revival possible. There had to be some years of persistent advocacy of the claims that hardy plants had upon all who were concerned with the decorative aspects of the garden, before any considerable proportion of them could be diverted from the various tender plants that had for many years been regarded with much favour. Moreover, some thirty-five years or so ago so little was known of the finest of the hardy plants that much educational work had to be accomplished before any material change could, with success, be effected. In this work the Gardeners' Magazine rendered valuable service in various directions.

Hardy Plant Improvement.

Another important factor was the splendid service rendered by those members of the trade who had never lost their faith in them, but had continued the improvement of some of the kinds throughout the period in which the interest in hardy flowers was at its lowest ebb. For example, the late Mr. William Kelway had become greatly interested in the herbaceous pæonies before the massing of tender bedding plants in the flower garden had made much progress, and, gathering up all the most meritorious varieties he could obtain, he went steadily on with his work in improving the form and increasing the size of the flowers and developing new shades of colour. In this he achieved a high degree of success, and by his example induced others to take up the work of cross-fertilisation, some of the most noteworthy achievements being such distinct and beautiful varieties as Exquisite, Lady Curzon, Lady of the West, Lord Rosebery, Madame Calot, and Soltatara. Some years later the pyrethrums were taken in hand by Mr. Kelway, and, as the result of this pioneer work, large collections of flowers of both kinds were exhibited both at South Kensington and Regent's Park, and these assisted in obtaining for hardy plants the attention that had for so long a period been denied them.

Taking down from my bookshelves some trade catalogues that were issued in the early fifties. It is found that, concurrently with the progress that was being made in the West of England in the improvement of pæonies and pyrethrums, some of the Scotch growers, notably the late Mr. John Downie, were busily engaged in the development of herbaceous phloxes, pansies, and pentstemons. It is exactly forty years since the late Mr. John Forbes established

A CHARMING IRIS GARDEN BY THE WATERSIDE (CLANDON PARK).

Make your Garden a blaze of beautiful colour from early Spring to late Autumn

Kelway & Son, the Royal Horticulturists, of Langport, Somerset, offer you the benefit of their experience of over 60 years in matters horticultural, to help you to make the most of your garden—to make it a Garden Beautiful. In the famous

KELWAY COLOUR BORDER

(Regd.)

Nature's beautiful gifts are planned by Kelway's method, which ensures a riot of glorious colour, a constant succession of ever-changing hues throughout the greater part of the year. The cost is only 15/- to 25/- for 10 square yards, and the plants are delivered to you carefully packed and labelled, and arranged in the correct order for planting.

NOW IS THE TIME TO PLANT.

BEES' NEW CR

THE PLANTS ILLUSTRATED AND DESCRIBED ON THESE PAGES ARE PART OF A CONSIGNMENT COLLECTED BY MR. FORREST ON THE HIGH A MALACOIDES, WHICH ARE NOW UNIVERSALLY GROWN. ORDER A FEW OF EACH NOW. DO IT NOW, "LEST TH

Buddleia macrostachya yunnanensis.

Adenophora megalantha (Illustrated). This is a hardy perennial growing about 18in. in height, and producing with wonderful freedom, along two-thirds of the upper part of the stems, large handsome bells of a particularly pleasing shade of pale porcelain blue. Its habit will fit it for either border or rockery. It needs no staking unless it is grown in very rich soil. If well exposed to the sun the growth is sturdy and erect. It is quite the handsomest of the Adenophoras, and we recommend it to our clients with the fullest confidence. **Strong flowering plants, 5/-.**

Buddleia macrostachya yunnanensis (Illustrated). The young leaves and undersides of the older leaves are covered with pure white woolly tomentum; flowers mauve, **fragrant,** in erect spikes. **Strong plants, 10/6.**

Codonopsis meleagris (Illustrated elsewhere in this issue). The habit and character of this striking species is well shown in the illustration. It is a strong growing alpine, and reaches a height of 9 or 10in. On the rockery, in a sunny or dry position, it will probably not be more than 6in. tall. The flowers bear a very striking resemblance to those of the Snake's-head Fritillary. The ground colour is a very, very pale porcelain blue, the reticulations are rich chocolate purple, and the centre or base is green. The habit of the plant is semi-erect. On the rockery we recommend it to be planted in a similar position to that which is recommended for C. ovata, that is where one can peer into the inside of the bells without stooping. **Strong plants, 7/6; a few extra strong, 12/6.**

Adenophora megalantha.

Delphinium lichiangensis. This hardy perennial species grows somewhat taller than D. chinense, but is not so heavy in appearance as D. formosum. The colour is a bright Salvia blue, the flowers are of good size, and are freely produced on strong, erect stems. It will prove very useful for cutting, and will make handsome groups in the border. Growing amongst other Delphiniums, although bearing some resemblance to chinense, it strikes quite a distinctive note by reason of its distinct colour and habit. **Strong plants, 5/-.**

Dracocephalum bullatum. When this species was shown at the Royal International Horticultural Exhibition in London, it created a very considerable amount of interest. It is a plant much in the way of the splendid D. grandiflorum, but rather more lax in habit, and with the foliage of a softer texture, while the flowers, instead of being blue, are of a very refined shade of purple. It is a plant which to show itself at its best must be planted in a sunny, well-drained position on the rockery, or even on the border, and be allowed to remain undisturbed for several years. It will then form a dense mat of shoots, clothed with foliage, and each shoot will be tipped with a large head of richly-coloured flowers. Strong flowering plants, **7/6;** a few extra strong specimens. **12/6.**

Dracocephalum tanguticum (Forrestii). The habit of this very striking species is shown in the illustration, which represents, by the way, a rather poor specimen in a 3in. pot. Plants in the open grew into bushes 12in. or 18in. in height, and as much through in a couple of seasons. When in bloom they were a really splendid sight. The flowers, as will be seen, are produced in dense spikes. From nearly the base of each shoot to the very top, the flowers are produced in rapid succession for a period of several weeks. It flowers in late summer and autumn, and like other species of this genus it delights in a sunny position. The colour is a glowing shade of violet-purple, giving off some striking wine-red and purple tints in strong sunshine. **Strong plants, 7/6; a few extra strong at 12/6.**

Incarvillea brevipes. We first offered this plant—which, by the way, was one of Mr. Forrest's first introductions—several years ago, and the demand, owing no doubt to the plant's attractiveness and value, rapidly exceeded the supply, so that for a season or more we have been unable to execute orders for it. The plant very much resembles I. grandiflora, but it is far superior to that species, as well as quite distinct. Perhaps the most notable feature is its habit of flowering in early summer. In May, while the other Incarvilleas have hardly commenced to make growth, this plant, from established roots, is a mass of bloom. Brilliant rosy crimson is a very scarce colour at that time of the year, and no doubt this fact contributes largely to the success and popularity of this fine plant for herbaceous borders. The plant does not imitate I. Delavayi in that habit of occasionally lying dormant for a whole season. Out of the thousands we have grown we have never known a solitary plant which did not grow freely every season The colour, a brilliant rosy crimson, is accentuated by the pale yellow of the throat. **Strong roots, 1/-; a few extra strong, 1/6.**

Potentilla Veitchii. This shrubby Cinquefoil was sent home by Mr. Forrest as P. fruticosa alba; it proves, however, to be identical with one sent home previously by Mr. Wilson. The white flowers are very freely produced, and the effect of a well-grown bush is quite excellent. It will probably obtain similar dimensions to P. fruticosa, which it very much resembles in habit of growth. **Strong plants, 3/6 and 5/-.**

Primula angustidens. This species resembles P. Poissonii to a considerable extent, but is recognised as distinct by the botanical authorities. The difference from the horticultural point of view is that it is more free flowering; the plants instead of producing a solitary spike often throw up from one crown several stems bearing several whorls of the brilliant purple-violet flowers, each flower measuring 1in. across. Like P. Poissonii, the foliage is bright and glossy, and the plant itself is a very vigorous, thrifty grower. There is no danger of this plant "going off" in the winter; it seems to revel in a moist situation, and will, no doubt, make an excellent bog plant. **Strong plants, 5/- and 7/6.**

Primula farinosa Beesii. This plant was raised from seed sent home by Mr. Forrest, and is an interesting instance of the wide distribution of the British Bird's-Eye Primrose. It is, however, a very well-marked variety, much larger in all its parts than we have ever seen the type attain under cultivation, while the flowers are a very bright shade of rosy pink. **Strong plants, 1/6.**

Primula pulchelloides. This primrose belongs to the class of which P. sikkimensis may be taken as a type. The flowers are more or less collected together in a head at the apex of a slender stem, and droop slightly. The leaves, stems, and even the flower calyces are covered very thickly with a yellow farina which forms a pleasing combination with the pretty pale lilac flowers, more or less flushed with rose. The plant will reach a height of 6in. to 9in. **Strong flowering plants, 3/6 and 5/-.**

Primula Beesiana. Velvety purple. **1/6.**

Primula Bulleyana. Buff, orange, apricot, and scarlet. **1/6.**

Primula Forrestii. Golden yellow. **1/6.**

Primula malacoides. Rosy lavender. **6d.**

Primula malacoides alba. New, white. **1/6.**

Primula secundiflora (Illustrated). The illustration which we reproduce is from a photograph taken by Mr. Forrest of plants growing wild on the Lichiang Range, at an altitude of 13,000 feet. It is a vigorous-growing species, with much the same habit as P. sikkimensis, but the colour of the flowers is quite unlike any other Primula we have seen. It may be readily described as a dull but rich purple. It is such a colour as would be well set off in contrast with brilliant orange. The flowers are scented, quite large in size, and are produced with wonderful freedom. It is interesting to note that the botanists consider this species to be identical with P. vittata, but the plants which are in cultivation under that name are totally distinct from this plant, which we are now distributing for the first time, and which is a vastly superior thing. It appears to be a lover of damp places, but ample drainage is essential, and we consequently recommend that the plant be grown on a raised mound, which would permit of the roots descending into a moist sub-strata beneath. **Strong plants. 7/6.**

Primula secundiflora.

Roscœa cautlioides. This is a new Chinese plant of absolutely faultless beauty. It was sent home by Mr. George Forrest while on one of his earlier plant hunting expeditions on our account. The colour is a pale yellow, very soft and delicate, fuller in tone than "primrose," infinitely more refined than "canary"; in short, quite as charming a tint as we ever expect to see. In texture, the petals are worthy of comparison with the Poppy. The leaves remind one of an Iris, springing from the base of the 9 to 12 inch stems, which carry as many as 6 or 7 blooms and buds. The roots are fleshy, almost tuberous, and, if planted 4 or 5 inches below the surface in sandy loam, will prove hardy. Test plants in the open ground have come safely through the past winter on our exposed Nursery in N. Wales. **Price for flowering-size plants, 7/6; a few extra strong, 12/6.**

CORRESPONDENCE INVITED.

"WORTH ITS WEIGHT IN GOLD."—Such is a Reader's opinion of THE ENCYCLOPÆDIA OF GARDENING, by T. W. Sanders, F.L.S. Price 3s. 10d., post free, from the Publishers, 148-9, Aldersgate Street, London, E.C.

himself in business at Hawick, and entered on the improvement of phloxes and pentstemons, and certain other classes of hardy plants.

The aim of these pioneers and of the other raisers of new forms of these beautiful plants has been to improve the form and increase the size of the flowers, and extend the range of colouring. How well they have succeeded in effecting their object is evident in all gardens in which these perennials are grown. In the case of the phlox, the flowers of the present-day varieties have a circular outline, and in diameter exceed by at least 50 per cent. the blooms of the older forms, and the development in colouring is little short of marvellous. In proof of this we have only to refer to the orange-red Cocquelicot, the orange-scarlet Etna, the pure white Freifraulein von Lassberg, the salmon-pink Elizabeth Campbell, and the deep violet-blue Le Mahdi. In the case of the pentstemons the efforts of the raisers have resulted in the production of a race with the plants more robust, the flower spikes of greater length, and the flowers larger and more horizontal than in the varieties now far removed from the type. Countess of Aberdeen, Fire Dragon, Lord Northcote, Mrs. L. Pullar, Mrs. E. Smith, and Talma may be mentioned as representing the highest type of the present-day pentstemons.

The Earlier Hardy Plant Nurseries.

Forty years must also have run their course since the late Mr. Robert Parker, who had for some time been in partnership with the late Mr. B. S. Williams, at Holloway, left the orchids and the stove and greenhouse plants, for which they were famous, established a nursery at Tooting for hardy plants, and gave the whole of his time to their development. For a considerable period he used to contribute large and interesting collections to the London shows; these stimulated much interest, and brought into prominence many plants that were comparatively unknown. He also did excellent work in connection with the Michaelmas daisies, which at that time contained a considerable number of varieties that were weedy and of little value for beautifying the garden. A few years subsequently the late Mr. T. S. Ware, imbued with a strong affection for hardy plants, gave up the business in which he had been so long engaged, and established, on a large scale, a nursery at Tottenham for their cultivation for commercial purposes. These two nurseries were the first that were established specially for hardy, herbaceous, and alpine plants, after their restoration to public favour, rendering valuable service in making the various kinds known, and distributing them amongst those who were desirous of enjoying the individuality of the many beautiful hardy plants.

Ascendancy of Hardy Plants.

Subsequent to these two nurseries having been established the taste for hardy plants increased at a rapid rate, and concurrently with this there was a remarkable extension in their cultivation, both in trade establishments and private gardens, and this extension has, happily, continued without a halt until the present time. In the course of time, and that of no great length, collections of hardy plants were to be found at all the nurseries of any considerable extent. Under the stimulus thus given, and the ever-increasing demands for novelties, new and rare species and varieties were introduced from various parts of the world, and strenuous endeavours were made at home, and with much success, to develop the leading kinds by cross-fertilisation. For evidence of this we have only to turn to a catalogue of hardy plants issued within the last few years, and compare it with one that was published about a quarter of a century ago. It will at once be found that there have been large increases in a number of instances that have resulted from judicious cross-fertilisation and careful selection. To mention but a few, there are the delphiniums, which now form a magnificent group; the plants stately in growth, the spikes of great length, the flowers, both double and single, of large size ranging in colour from the purest white to the deepest purple on the one hand, and to the most brilliant blue on the other. These we chiefly owe to the efforts of Messrs. Kelway, Perry, and Blackmore and Langdon. Conspicuous among the more recent of the additions that have been made to the delphiniums are Daniel Osiris, Excelsior, Monarch of All, Phyllis Kelway, Rev. E. Lascelles, and Statuaire Rude. The Michaelmas daisies, for which we are, in a large degree, indebted to Mr. Ernest Ballard, an enthusiastic amateur, Mr. E. Beckett, Messrs. Barr and Sons, and the late Rev. Wolley Dod, include exceedingly beautiful forms of Aster cordifolius, A. ericoides, A. novæ-angliæ and A. novi-belgi, especially notable being the double Beauty of Colwall and the remarkably fine Climax in the last-named group. The garden iris, amongst which the late Sir Michael Foster did such excellent work. The Oriental poppies, which have been contributed chiefly by Mr. W. J. Godfrey and Mr. Amos

AN ORNATE FOUNTAIN BASIN WITH WATER LILIES (DOWNSIDE, LEATHERHEAD).

Perry, comprise several distinct shades of colour, as the salmon Edna Perry, the terra-cotta Lady Roscoe, and Perry's White. The garden pinks, raised, for the most part, by the late Mr. James Douglas and Mr. B. Ladhams, include several

AN ATTRACTIVE ROCKERY ARRANGED WITH CHOICE ALPINES OF MODERATE GROWTH (LEONARDSLEE).

perpetual varieties, as Ernest Ladham and Progress. The spring-flowering alpine phloxes, of which many originated with the late John Nelson have been so greatly improved as to form an important group of rock plants. Many well-marked varieties of species of campanulas and other plants have been obtained by selection, and greatly enrich collections. The early-flowering chrysanthemums that now form so valuable a group of hardy plants for beautifying the garden in September and October may be said to have had their foundation laid by the late Mr. Piercy, who raised a few, but the chief value of his work consisted in the persistent efforts he made to keep them before the gardening community. Especially noteworthy among these being Carrie, Goacher's Crimson, Madame Marie Masse, and its numerous colour sports. Montbretias, as we now know them, are quite modern introductions, and the finest of the varieties we now have were raised by Mr. G. Davison, of Westwick, his most noteworthy production being the orange-yellow Star of the East.

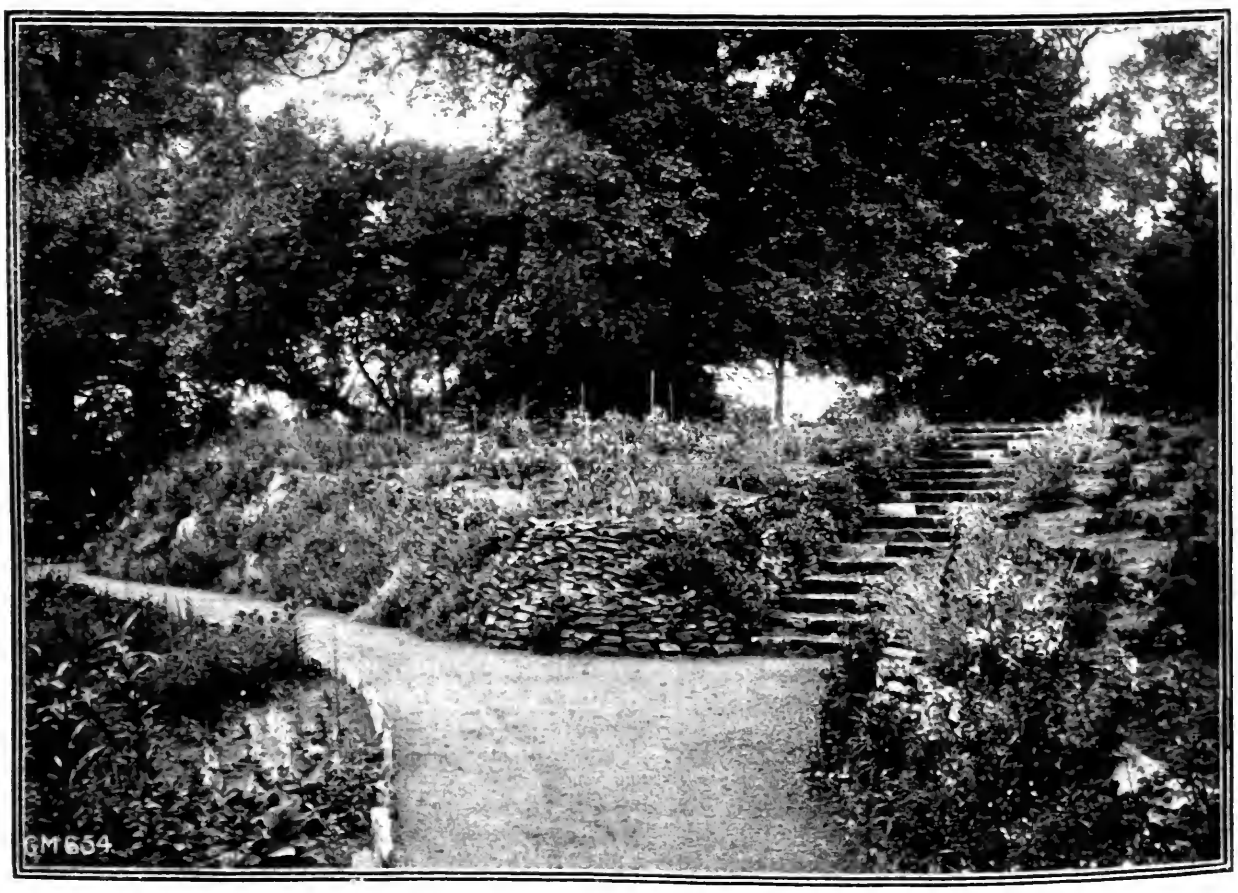
With the introduction of new and little-known plants from abroad, the improvement of certain genera by cross-fertilisation, and the prominence assigned to the finest kinds at the exhibitions, the development of hardy plants proceeded apace, and it has now assumed proportions of which but few have an adequate idea. It is not possible to set out in detail the number of nurseries in which hardy plants form a special feature, the area devoted to them, or the number of persons engaged in the industry. It can only be said, and that will probably be sufficient, that hardy plants grown for sale must, at the present time, occupy an immense area, and that those engaged in looking after their needs and dispatching them to purchasers would make a respectable army.

Important as have been the results obtained from cross-fertilisation and selection, they by no means exhaust the activities of those engaged in the hardy plant industry that have had for their object the increase in the number of forms deserving of general cultivation. Within a short time of the industry having been placed in a position that promised well for its future, plants of known merit that had not been introduced to this country in any considerable numbers were obtained from other parts of the world as quickly as possible, and multiplied as rapidly as the art of the propagator would permit. Collectors were sent in quest of choice alpine plants to the mountains of Central Europe, the Caucasias, and the Pyrenees, and, as the result of their activities, immense numbers were annually sent to this country. In addition a large number of new Chinese plants of a quite distinct character have been introduced to cultivation, of especial interest being the beautiful primulas, notably P. Bulleyana, P. Forresti, and the exquisite P. Littoniana introduced by Messrs. Bees, Lim., P. pulverulenta, and P. Knuthiana, introduced through Messrs. J. Veitch and Sons, and now generally grown. Some important additions have been made to the hardy primulas by the exercise of the hybridists' art.

There are not wanting hardy plantsmen who regard the management of a nursery devoted wholly or in part to their favourite flowers as a pleasant pastime. Pleasant it may be, but it can hardly be described as a pastime. An ordinarily good collection will include about two thousand species and varieties, and of a large proportion of these the stocks will consist of many hundreds of plants. To keep a collection containing so large a number of units in such order that the risk is reduced to a minimum of the different kinds becoming intermixed, requires a well-devised system and constant watchfulness. Not less necessary is it to exercise such care that the several classes of plants are placed under the conditions favourable to their healthy growth, and the difficulties there may be are somewhat accentuated by the plants having to be grown in small pots to meet the requirements of business.

Rock Gardening and Alpine Plants.

One of the most interesting features in the growth of the hardy plant industry has been the remarkable development of a taste for alpine and other plants that thrive on well-planned rockeries. At no period in the history of gardening in this country has the interest in the exquisitely beautiful flowers of the Alps been so great, or such strenuous endeavours made to cultivate them with a full measure of success as at the present time. No longer is it assumed that anyone who has some knowledge of gardening can construct a rockery adapted to the requirements of a wide range of plants from mountainous regions as was the case in the olden days. This is now recognised as work that requires taste, a knowledge of the conditions under which the several classes of plants thrive, and experience in the building of rockeries. Accordingly this is now entrusted to those who have afforded ample proof of their ability in dealing with it, and the success



AN INTERESTING WALL GARDEN (NUNEHAM PARK).

that has been achieved as a consequence thereof has contributed in a marked degree to the high degree of popularity that rock plants now enjoy. The construction of rockeries has almost assumed the position of a fine art, and those who visited the Royal International Horticultural Exhibition held at Chelsea last year will remember with pleasure the splendid examples of rockery construction that were carried out by Messrs. Pulham and Son, Messrs. R. Wallace and Co., Messrs. J. Cheal and Sons, and also by Messrs Backhouse and Son, Messrs. T. S. Ware, and others. In the modern rockery we have two types, one formed with large rock masses for the accommodation of strong-growing plants, that attain a large size, and are capable of producing a bold effect; and the other constructed with ledges and fissures specially adapted to the smaller-growing kinds which constitute some of the most beautiful of the denizens of alpine regions.

Water and Bog Gardens.

Hardly less noteworthy than the advances that have been made in rock gardening has been the development of a taste for moisture-loving plants during the past quarter of a century. Well within the recollections of many of those who read this brief sketch the only water lily found floating on the glassy surface of lake and pool in British gardens was Nymphæa alba, which has its home in this country. Now the number of water lilies in cultivation is very large, and, although differing in merit, all are more or less beautiful. There are varieties so strong in growth as to require a small lake or spacious pool for their proper development, and there are others so moderate in growth that they can be successfully grown in the basin of a quite small fountain, or in the simplest of pools. Indeed, there are several, such as some of the varieties of N. Leydeckeri, and those of N. pygmæa, that require so little room as to admit of their being grown in shallow tubs three feet or so in diameter. On the other hand, there is a host of varieties available for those who have ample water space at their command. There are, for example, the varieties of Marliacea, which afford a wide range of colour, the pure white Gladstonei, the pink John Brydon, the rich purple Robinsoniana, and the rich crimson Sanguinea, to name but a few of those in general cultivation. Water gardens of wondrous beauty may be formed with nymphæas and other aquatics suitable for growing in association with them. It would be both pleasant and interesting to refer to some of the newer varieties, but it must suffice to say that nymphæas now form an important feature in hardy plant collections, and that for the greater proportion of those available for cultivation we are indebted to M. Latour-Marliac.

The development of bog gardening has given added interest to hardy plant culture, and the bringing into prominence of the many beautiful plants that thrive in moist situations has rendered it possible to materially increase the charm of the margins of lakes and ponds, and the low banks of streams that have a fall so slight as to proceed slowly on their way through the garden. Very different is the appearance of a lily pool, whether large or small, with a fringe formed with such plants as the Water Violet, the Bog Bean, the Arrow Head, the forms of the Marsh Marigold, the Water Soldier, and other plants thriving under similar conditions. For planting in bogs, artificial or otherwise, there is a wide range for selection, and the lists that are to be found in the trade catalogues show that their importance is recognised both by owners of gardens and those who are engaged in the hardy plant industry.

GEORGE GORDON.

DELPHINIUMS.

As the result of much enterprise and perseverance on the part of those who have taken an active interest in cross-fertilisation among hardy herbaceous plants, the perennial larkspurs form a group that is remarkable for its distinctness and beauty, and quite unsurpassed for the production of striking colour effects in the hardy plant garden. Within quite recent years they have undergone an immense improvement in habit, in the flowers, and flower spikes, and in the range of colours, which is now very great. The varieties are now of so high a degree of excellence that a hardy flower border would be very indifferently furnished if it did not contain a selection from them. Delphiniums are now to be obtained in numerous shades of colour, varying from the palest silvery-blue to the deepest indigo, while some of them possess a pink and purple tinge, with their centres ranging from pure white through cream and brown. There are also varieties with white flowers.

DELPHINIUM CORONATION.

One of the many beautiful varieties raised by Messrs. Kelway and Son, Langport. The flowers are rich purple and blue.

Delphiniums are at their best during June and July, but, in a number of instances, a second display of bloom can be had by cutting down the old flowering stems, when new growths will quickly take their place, and carry the display of blossom on into the autumn. Delphiniums are not very particular as to soil or situation, as in almost any good garden soil they will attain to a high state of development. A deeply-cultivated and richly-manured loam suits them the best, and, given such a rooting medium, they frequently attain a height of eight or ten feet. A sunny position is preferable, but they will succeed in partial shade, the latter frequently causing them to continue in bloom for a longer period. Very attractive borders can be planted with delphiniums alone, but when the flowering season is over they appear rather dull and uninteresting. Probably delphiniums appear at their best when tastefully arranged in bold groups in the herbaceous borders in conjunction with other hardy perennials.

Planting should be accomplished in the spring, and preferably before growth commences, although it can be successfully performed until the end of March. Cuttings of young shoots may be taken at this season of the year, or later in the summer, and when it is required to increase named varieties this method or division of the root must be practised, as seedlings seldom come true to character. Delphiniums can be raised from seeds sown at the present time in a cold frame, or they may be sown as soon as ripe in the summer.

It is important to keep the plants correctly staked and tied, and support should be given them in the early stages of growth so that the flower stems may be kept erect from the first.

Varieties are very numerous, and the following will form a selection admirably adapted to the requirements of those who are commencing the cultivation of these effective flowers under name. Albion, semi-double, pure white: Bella Donna is a beautiful form, with sky-blue flowers, but Persimmon is an improvement upon it, and the handsome Bella Donna semi-plena is a charming variety with semi-double flowers; Capri is a bright azure-blue; Coronation is a handsome variety, the flowers deep blue and rich purple; Dorothy Kelway, deep sky-blue, suffused rosy-plum; Goliath, deep violet-blue; Lady Rowena, indigo-blue; Moerheimi, white; Rev. E. Lascelles, dark blue, with light centre; Statuaire Rude, rich blue; and True Blue, bright blue, with dark centre.

J. GARDNER.

SHRUBS FOR DRY BANKS.

Mounds and hillsides where the ground is naturally dry and sandy are among the most difficult positions to clothe satisfactorily with shrubby vegetation, especially when the introduction of better soil is impossible, and only a comparatively small sum of money can be expended on the undertaking. But that it is possible to effect this may be noted in various directions where bare and ugly sites have been transformed in the course of a year or two into positions of beauty by the use of the right kind of plants.

The preparation of such ground for the reception of plants usually means the removal of all coarse herbage, such as weeds and grasses, the forking out of undesirable roots such as nettles or couch grass, and forking the ground over 9 or 12 inches deep. In fact, for some of the most suitable shrubs for the position it would be unwise to dig the ground deeply or manure it, as such treatment would encourage rapid and rank growth, the roots would be deficient in fibres, and flowering would suffer. On the other hand, the poor and moderately hard soil tends to keep the plants dwarf and bushy, the roots fibre well, and the maximum amount of flower is obtained. A point to remember, however, is that small plants stand a better chance of success than large ones, therefore it is advisable to use quite young stock rather than try to create an effect at once by planting older specimens. It is also necessary to keep the plants watered during dry weather for the first year, and, if possible, give the ground a mulch of leaves to keep it from drying rapidly. Weeds must be kept down until the plants are vigorous enough to crowd them out, otherwise some of the little shrubs may be smothered before they are in a position to compete with the natural vegetation.

By exercising a little care and forethought in the arrangement of the plants, a natural effect may be obtained which will be more in keeping with the character of the ground than any formal distribution of plants would be. Thus, there should be no hard line between one kind of plant and another; rather let the outline of each group be irregular, and encourage the different sorts to intermingle. Neither should a formal border or margin be allowed, but let grass and plants meet, and arrange for the shrubs to form a broken outline. Then the proper arrangement of tall and dwarf shrubs adds much to the general appearance. By allowing tall-growing subjects to approach the front, and groups of dwarf plants to recede here and there, a broken and irregular effect is produced, which adds greatly to the appearance of the plantation as it advances in age. The presence of large stones about the ground is not a great disadvantage, for a piece of rock standing in the midst of a mass of gorse or patch of heath adds a picturesque touch to the scene.

In districts where pine trees abound it is sometimes possible to provide a very pretty feature by underplanting a group of mature pines. This may be effectively accomplished by using the various kinds of erica and culluna. The spring-flowering and autumn kinds can either be used separately or intermingled, but in either case bold groups of each kind should be formed. In the milder parts of the country a wide selection of species is available, for all the semi-tender, Southern European ones may be used, and these, by their greater size, add considerably to the effect of a group composed chiefly of the British species.

For general planting, however, other subjects are perhaps more generally useful than the heaths. The double-flowered gorse is one of the best, and the poorer the ground the better it seems to do. In light, sandy, or gravelly soil, it forms short growths, grows about 2½ feet high, and blossoms profusely. Its great advantage over the single-flowered gorse is that there are no disfiguring seed pods to follow the flowers. Another useful plant is found in the French gorse (Ulex Galli). On poor soil this forms dense cushion-like masses a foot or so high, each clump appearing as a ball of gold in September. Associated with late-flowering heather and ling it is most attractive, and many hillsides and commons in the south and west counties are ablaze with these associated plants every autumn. On chalky soils the common juniper (Juniperus communis) and the savin (Juniperus sabina), with its several varieties, may all be used.

Lavender grows well in combination with gorse, also the Cotton Lavender (Santolina chamæcyparissus), whilst the various rock and sun roses, species of helianthemum and cistus, are excellent for the purpose. They, more particularly the latter, thrive excellently in the poorest soil, and certainly stand the winter and flower better in poor than in rich ground. The Brooms, species of cytisus and genista, especially the common Cytisus scoparius, are excellent for the purpose, but it is a good plan to cut them over annually after the flowers have faded, otherwise they become leggy. There is one broom, however, Genista virgata, which may well be used as a dot plant to give height here and there. In quite poor soil it attains a height of 10 or 12 feet with a like spread, and blossoms finely. Berberis aquifolium is a good evergreen for the purpose, and it may either be allowed to attain a height of 3 or 4 feet, or be kept quite dwarf by an annual pruning. Prunus spinosa serves for a group where a tall-growing plant is required, whilst its double-flowered form would also be excellent for the purpose could it only be obtained in larger quantities. Cydonia Maulei is another shrub which deserves attention, although it is less at home in quite poor soil than some other subjects. Should the planter desire to introduce trees into the group, then the common birch might be used with effect, for the silver trunks standing amongst the greenery of the undergrowth is always attractive. The mountain ash is another effective tree for such a position, whilst the white beam tree (Pyrus aria) is also suitable. Both these are very attractive during late summer and early autumn, when laden with bright-coloured fruit; they, however, lack the graceful outline of the birch, and are, perhaps, less effective than the mature trunks of Scots pines, though still beautiful.

Kew. W. Dallimore.

Agathæa cœlestis.—This, popularly termed the Blue Marguerite, is an easily-grown and pretty greenhouse plant. It is of bushy growth, and the daisy-like flowers are about an inch across, the spreading florets being of a pleasing shade of light blue. It will flower for months together, and is very useful for cutting from.—W.

MAIN CROP AND LATE POTATOES.

Special care should be taken in the preparation of the seed tubers, some time previous to planting, by encouraging strong and sturdy growths. This alone will prevent those unsightly gaps so often observed in plots that are planted direct from the seed sacks. At the time of planting such tubers appears to be quite as perfect as those boxed up, but they may possess no living eye, hence the blank spaces. No growth will result, and the tuber, if lifted, will be as sound as the day it was planted.

To guard against this, place the tubers eyes upwards, thickly, in boxes, or on shelves in a light and airy fruit room or other store-house. It will take longer to plant and require more care if this method is followed, but the ultimate result will amply repay the trouble taken. Therefore, for the garden crop, the time taken up will not be spent in vain.

A very important factor in the production of good heavy crops of potatoes is to procure all, or part, of the crop for seed purposes from a distant source each season, whether it be from Ireland, Scotland, or neighbouring counties, as an appreciable and pleasing difference will be noticed in the results.

The middle of April is early enough for maincrop planting, and the ground should have been brought into good condition either by ridging (a good plan) or trenching, and any manure used should have been buried quite two months previous to planting. Fresh manure is liable to force sappy top-growth, foredoomed to disease, hence it should be avoided. Potatoes vary greatly in various localities, and in different soils, therefore it is difficult to name "the best" late varieties. A potato that has stood, and is standing, the universal test, is a good selection of Up-to-Date, and for flavour and cropping, with good disease-resisting powers, it is still the chief variety to grow in quantity. White City is good in flavour and a long keeper.

Plant late varieties in rows two feet six inches apart, and allow eighteen inches from plant to plant. Ply the hoe frequently, lightly earth at the first sign of growth, and apply a dressing of superphosphate, or potato manure, between the rows, previous to earthing, if the growths are at all weak. G. Ellwood.

Swanmore Gardens.

THE ORCHARD HOUSE.

As a rule the orchard house contains a miscellaneous assortment of peaches, pears, apples, plums, etc., in pots; but it would be an advantage if the several kinds could be grown separately; certainly peaches and nectarines require a compartment to themselves, for the earliest crop will now be stoning, if the fruits have not already passed this trying ordeal, and very little progress will be noticeable. Disbudding and pinching having been carried on conjointly with thinning, vigorous trees will still require constant attention in the pinching of shoots and laterals. Top dressings and careful feeding, which may be described as the mainsprings of success in pot fruit culture, must be continued until the fruits are nearly ripe. Whatever is used—rich top dressings, liquid manure, guano, or soot water—changes are necessary, and supplies of moderate strength applied at frequent intervals give the best results. Plenty of water is necessary at this stage, and if once the balls of pot trees become dry the effect on the crop is fatal. Syringe the trees twice daily with soft water, and half a bag of soot immersed in the tank will improve and stimulate the foliage, and help to keep red spider and other pests in check.

Warter Priory Gardens. F. Jordan.

EUCHARIS GRANDIFLORA.

Twenty or more years ago no collection of stove plants was considered complete unless it contained several specimens of Eucharis amazonica, as it was then termed. But more recently its culture has unfortunately greatly declined, and healthy floriferous plants are the exception rather than the rule. This decline may be attributed largely to the appearance of the bulb mite (Rhizoglyphus echinopus), which, in many gardens, spread rapidly among the eucharis, and, in many instances, did much injury to both large and small plants.

Probably no plant parasite, even including the ubiquitous mealy bug, received so much journalistic attention. Successful cultivators stoutly contended that the presence of the bulb mite was the effect of unhealthy plants and not the cause, whilst those whose plants were infested declared themselves equally positive that the dreaded mite was the cause of all their trouble and anxiety. As always, the scientists were mostly on the side of the pest, declaring that the mite was the person to be considered, and forthwith busied themselves in the endeavour to formulate remedial sprayings and dressings. It seemed, however, that in many cases the greediness of the cultivator was to blame. For in his anxiety to obtain three crops of flowers each year he had to resort to excessive dryness at the root so as to reduce the necessary period of rest to a minimum, thus weakening the constitution of the plants. In its native state the eucharis, no matter how parched the soil may appear to be during the dry season, finds sufficient moisture within the reach of its long, fleshy roots to sustain it until the rainy season arrives. This being so a very little consideration will show the folly of drying off pot plants, for here the roots are curled round and round the insides of the porous pots, and if water is withheld the plants must quickly suffer.

It is only reasonable to infer that if nature had intended the eucharis to live under desert conditions for a portion of each year she would have given it deciduous bulbs of a different structure. An examination of a eucharis bulb will show that it is composed of thick, fleshy scales packed comparatively loosely—a form of structure not at all adapted for withstanding tropical drought.

The bulbs of many liliums have even fleshier scales, which are also more loosely disposed, but these are plants of temperate regions, yet they are deciduous, and have not to support foliage during the dry season.

The most suitable and common-sense methods of culture of the eucharis plants are to treat them as evergreens, and consequently at no time to allow them to become quite dry at the root, and to flood them with water during the comparatively brief period of growth. At that season the eucharis may be considered as a tropical bog plant, and treated accordingly. Shade from direct sunshine during the summer months is essential, and the best soil is fairly stiff loam, with a little leaf-mould and sufficient sand to permit air to reach the roots. Whilst new leaves are being made frequent applications of diluted cow manure are beneficial. When repotting becomes necessary great care should be exercised to avoid mutilating the roots, for the eucharis resents root disturbance. If the pots are over-full of bulbs the roots should be washed in a tub of lukewarm water until the old soil has been removed, and the roots may then be disentangled without injury, and, if carefully handled, will suffer but little in being repotted.

Cecil Aubrey.

BUSH HARROWING LAWNS.

When tennis courts, bowling greens, hockey grounds, and all kept lawns are well managed they are a pleasure to look at and a joy to play upon. Unfortunately in many instances the amount of money required to keep them in a highly satisfactory condition, especially club greens and courts, is lacking, and whenever play ceases in autumn the lawns are left to look after themselves.

Several examples of greens of this kind have come under my notice lately, greens where the coarser grasses have been allowed to smother the finer ones, and the surfaces covered with worm casts. The worm casts serve as a top-dressing to lawns, and an excellent top-dressing they make if the grass has been kept short, and they are well broken up and distributed over the surface in March. More often, however, than otherwise, no heed is taken of this rich manurial earth until the time arrives for play, and then, instead of spreading the casts, a roller is applied, with the result that the surface of the ground becomes so rough as to be very like the outside of an orange-skin.

Besides creating an uneven surface by rolling the ground while the worm casts are present in their natural form, another evil is created. The holes made by the worms are useful in carrying off surface water and airing the soil, and when the ground is rolled without an attempt to distribute the casts, the holes are sealed up. On heavy soils this method of treating greens and lawns often leads to sourness, the death of all the finer grasses, and a growth of obnoxious weeds. The grasses should, of course, be kept cut close during the autumn and early winter months to allow light and air to reach the dwarfer forms, and at the same time to expose the worm casts, so that they may be properly utilised for the benefit of the ground. This is best accomplished in dry weather in March by bush harrowing.

There are various kinds of bush harrows employed for this purpose, and perhaps the best of the old sorts are gates, or something like gates, with brooms fastened between the spars. Birch comes next in point of value, and then the twigs of beech. Harrows made of these, and pulled over the surface of the ground will not only break up and distribute the casts, but will also leave the larger portions of them in the hollows, thereby aiding in levelling the ground. The holes made by the worms will be left intact to drain off the water, and when the roller does go over them no harm is done. Lawns well cared for in this respect usually retain a healthy and vigorous growth of grass, with a complete absence of acidity in the soil, and but little, if any, moss under normal climatic conditions.

Even although bush harrowing of lawns in spring is of considerable value in retaining the soil and herbage in a fit condition, it is only within the last few months that I have met with any special appliance for the purpose. This is something like what we call a "yard brush," made about five feet long, and with a cross-bar at the end of the handle for pulling it by. When these become known and sufficiently appreciated, especially in the neighbourhood of towns where substitutes are scarce, there is a likelihood of finding the tennis courts and bowling greens in a much happier condition than many of them are at present, both in private gardens and public parks, and in not a few club grounds.

Hibernia.

PYRUS JAPONICA.

This old favourite, which was introduced from Japan in 1815, is now a gorgeous sight, with its branches, on which the leaf points are just showing, thickly covered with bright crimson-scarlet flowers. In the south-west its first blossoms often expand in January, but, generally, it is not until the month of March that it presents a really striking effect. This year, when everything is so early, however, it is already in full bloom. It is commonly met with in cottage and farmhouse gardens, and the sight of a large plant trained on a whitewashed wall, with hundreds of scarlet flowers clustering on every spray, and glowing in the morning sunlight against their white background, is brilliant in the extreme.

Though generally trained on a wall, this pyrus will make a handsome lawn shrub if allowed to grow naturally, and will attain a height of ten feet or more. When grown in this manner it is rather later in flowering than if given wall protection, but in open positions blooms with equal freedom. After hot summers it generally produces fruit, but rarely in such abundance as Pyrus Maulei, nor does the fruit assume such decorative colouring.

There are several varieties of this shrub with flowers ranging in colour from pure white, through flesh, pink, and red, to deepest crimson, but it is doubtful if any exceed the type in ornamental qualities. Pyrus japonica is possessed of great vigour of constitution, and often contrives to live and thrive under the most unfavourable conditions. A large shrub that was rooted up when in full leaf in the month of June, on account of the rock above which it was growing having to be quarried away, and with its bruised roots shortened to a quarter of their length, was planted, as an experiment, in good soil, recovered entirely in the following year, though it lost all its leaves after its transplantation, while the roots left in the rock-wall subsequently threw out growths about four feet from the summit, which developed into fine bushes that stood out from the perpendicular rock, and both grew vigorously and flowered profusely. It is also known as Cydonia japonica.

Wyndham Fitzherbert.

Lilac Hugo Koster.—Size counts for a great deal nowadays, and in this new lilac, which was given an award of merit by the Royal Horticultural Society on March 4, it was very manifest. The flowers were single, but individually very large, while they were borne in massive clusters, far surpassing in both respects the varieties shown with them for the sake of comparison. The flowers were of a lilac shade, but, having been brought on under glass, one cannot say much on this point. It is, I should say, more likely to be of value as an outdoor shrub than for forcing under glass, as it seems to be of very vigorous growth, and the flowers are borne on stout, erect stems.—S. W.

A Pretty Plant for a Small Vase.—Some vases do not allow of a sufficient depth of soil for plants that need liberal treatment, particularly if the spot is a sunny one. Having a couple so situated, I tried during the summer several different things with, at best, only fair results. At last I planted them with the variegated-leaved form of Sedum Sieboldi, and found this by far the most satisfactory of the different subjects tried. The beautiful glaucous leaves, with their central yellow blotch and the pleasing rose-coloured flowers later on, and finally the rich red that the leaves acquire in autumn furnished several distinct phases of beauty.—W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

IN THE WARM HOUSE.—Such plants as Ærides, Vandas of the V. tricolor section, Saccolabiums, Rhynchostylis, and allied orchids are now commencing to show signs of renewed vitality, and repotting or top dressing must be attended to. Plants that have lost their lower leaves become unsightly, and it is desirable, where this is the case, to turn the plants out of their pots. If they are watered a few hours previously the roots that have become attached to the sides of the pots are more easily removed than when the compost is in a dry state. After having shortened the stems to the desired length, a stick sufficiently strong to hold it in position should be tied to the plant. The drainage used should be clean. After fixiug the plant with the stick attached in the centre of the pot, work crocks about the base sufficient to secure it in position. As these orchids practically derive their sustenance from the atmosphere, live sphagnum moss, intermixed with charcoal and broken crocks, will be found ample for their potting material. T sphagnum should be well chopped and pressed moderately firm, and if mounded to the centre this adds to the good appearance of the work. Newly potted plants must be kept carefully shaded from bright light and be allowed a temperature as even as possible with ample moisture. In bright weather frequent dampings are desirable, and syringing the plants overhead will be found beneficial.

VANDA SANDERIANA is one of the most delightful species, but, unfortunately, the large plants that have been introduced during the last twenty-five or thirty years seem to have become "small by degrees," and one seldom sees a plant comparable with the large specimens exhibited and figured in years gone by. The difficulty of growing V. cœrulea has been surmounted by Mr. Alexander and Mr. G. Hunter, and it is probable that similar treatment will also be found successful for V. Sanderiana. There can be no doubt that the hot, steamy atmosphere so generally practised and advocated has been the cause of failure. I have frequently noticed that the cooler conditions of the intermediate house have enabled the plants to keep their vigour for a considerably longer period than has been the case under warmer conditions.

VANDA TERES, V. Hookeri, and the hybrid V. Miss Joaquin will also be showing signs of new growth, and the first-named is developing flower scapes. These should all have the full benefit of all available light, with ample heat and humidity. Whenever the outside conditions are favourable the plants may be freely syringed, and every encouragement given to assist them to produce their flowers to the best advantage. The decayed moss on the surface of the compost may now be removed and new material be added.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

B. GLOIRE DE SCEAUX.—These plants, after flowering, are best reduced to about half their length and rested. We do not use stem growths for cuttings, preferring to wait for the strong sucker-like growths which are usually forthcoming by the middle of April. When three to four inches in length these are inserted singly in 60's, and left in the propagating frame until well rooted. They are then put into their flowering pots (large 32's), and treated similarly to the above, and frequently fed after the pots have become filled with roots. Under these conditions they make fine pyramidal specimens, about three feet in height, and flower wonderfully well after the Lorraine varieties have finished their season.

SEMI-TUBEROUS VARIETIES.—These should have their growths left at full length after flowering, and when resting must by no means be allowed to become dry. They will now be producing young growths, which may be taken as cuttings, while from the leaf axils they will also produce tuber-like growths, which, inserted in pans or small pots, will soon make nice plants. Given liberal treatment they will flower freely in 48's. Of this section, Ensign, Julius, Emily Clibran, and Bank Hall Glory are worthy of cultivation for their fine display during the dull winter months. The compost we use for all the above begonias consists of two parts fibrous loam, one of leaf-mould, one of peat, and a little silver sand, burnt earth, and dried cow manure.

PLUMBAGO ROSEA.—This beautiful subject provides useful material for conservatories or house decoration, and its flowers may be utilised either for vases in rooms or for table decoration. It may be propagated by means of cuttings of the young growths, or by roots cut in pieces and inserted, as is practised in the case of bouvardias. Our practice is to propagate a batch of young plants, which are eventually flowered in 48's. Having taken the required number of cuttings, a batch of the year-old plants are cut back, allowed to break, then shaken out, and put into eight-inch pots. The points of both young and old plants are pinched occasionally until October, when they are allowed to flower. The soil and conditions we afford them are similar to those provided for begonias, and as they are gross feeders, when the pots are filled with roots they receive occasional top-dressings.

THYRSICANTHUS RUTILANS.—Having finished flowering, these may be cut back to the hard wood, to induce them to break into growth that will provide cuttings.—H. Prime, Hatfield House Gardens.

FRUITS UNDER GLASS.

PEARS.—A goodly number of pot trees of these is most valuable, especially in the North, where good pears are not over plentiful. They enjoy the best of food, and give excellent returns for liberal treatment, although many complain that fruits are difficult to set under glass. They must not be coddled in any way while in blossom. Guard against undue excitement, neither must syringing be indulged in too liberally; at the same time a dry, parched atmosphere must be guarded against, as this weakens the flowers and causes the fruits to drop later. Attend to pinching and disbudding, and thin the blossom buds where placed too thickly.

CHERRIES AND PLUMS.—The earliest of these which have finished stoning may have the temperature increased to 55 or 60 on mild nights with a corresponding rise during day for an hour or two with sun-heat, allowing the temperature to decline to 60 or 55 deg. afterwards. Keep a sharp look-out for weevils, as these pests will soon damage both fruits and foliage if not detected. The best method to get rid of them is hand picking, curled leaves should be picked off as soon as seen and burnt, as fumigation has little, if any, effect on them. Later trees of these fruits must be brought on under identical treatment as regards temperature, free ventilation, syringing, and watering. If the weather is favourable, the houses freely ventilated, and the trees kept clean, insects will generally pollinate these late varieties.

MELONS.—Where melons must be grown in pits heated with manure, now is a good time to commence operations. Fresh stable litter and equal parts of oak or beech leaves should be well mixed and turned over two or three times before making up the beds. Sow the seeds in 3in. pots, and by the time the plants are ready, violent heat will have subsided, and the ridges of compost will have become thoroughly warmed through, when planting may be carried out. Rich and very light soils must be avoided, as rampant growth follows with but few fruits. Melons cannot have too much sun and light; two plants to a light are sufficient. Place more soil firmly up to the plants as the roots appear, when in about fourteen or fifteen weeks ripe melons should be obtainable.

CUCUMBERS. — Spring-sown plants will now be in full bearing, and will require attention almost daily in pinching, tying, and thinning of fruits. Nothing is more injurious to the crop than to neglect to thin the young shoots and fruits when necessary. As the weather improves, and frames get cleared of bedding plants, they should be cleansed, and made ready for cucumbers, as recommended in a previous calendar.—F. Jordan, Warter Priory, York.

THE FLOWER GARDEN.

ROSES.—There has been unusual activity among roses this season, and many ramblers have made young shoots several inches in length. Such unseasonable growth is not at all satisfactory, as it is liable to damage from cold winds and frosts, which cannot help but have a serious effect on flowering. Fortunately, with hybrid teas, teas, and perpetuals, this premature growth is checked by pruning, as, usually, the buds nearest the tips of the shoots are the first to become active, while those close to the base remain more or less dormant after the shoots have been cut back in pruning. If the operation has been deferred until about the present time there is not much fear of the young growths becoming damaged. When pruning, one has to be guided by the habit of each variety; in the first place all weak and dead wood should be cut out entirely, then shorten back the stronger shoots to four or five sound buds. This will be found to suit most varieties of hybrid teas and perpetuals, also some of the stronger-growing teas, while others of this latter class, which are not so robust in habit, will not require such hard pruning. A dressing of rose manure lightly forked into the surface of the beds and borders after pruning will prove most beneficial, and the dressing should be repeated several times during the season. In many districts attacks of mildew are most detrimental to successful rose growing, but by spraying at intervals of a week to ten days, from the beginning of April throughout the season, with a solution obtained by dissolving one ounce of sulphide of potassium in three gallons of water, the effect of such attacks will be reduced to a minimum.

BAMBOOS.—These graceful subjects are usually planted in the vicinity of water, and in bog gardens, where they always produce a pleasing and sub-tropical effect, their green foliage imparting a freshness to the surroundings, especially valuable through the dull months of winter, when the majority of their neighbours are devoid of foliage. It is well known that it is not a necessity to have a pond or lake before one can grow bamboos, as these will thrive in any deep, rich soil, and when once established require very little attention beyond giving them a good mulching of cow manure annually in the spring. The selection of sites calls for a little judgment. They are quite at home in any woodland part of the pleasure grounds, if sheltered from the north and east winds. At no time should bamboos be planted in open and exposed positions, for although their hardiness may ensure their existence, in such places they are never effective. The next few weeks is a suitable season for planting and moving bamboos. When dealing with soil of a heavy nature add plenty of leaf-mould, as in this they will root freely and soon become established. During the first season after planting they will require close attention in hot, dry weather; never allow them to lack moisture at the roots, while a spraying once a day will assist them.—T. B. Field, Wych Cross Place Gardens.

CARNATION SHOW.

The SPRING SHOW of the PERPETUAL CARNATION SOCIETY will be held at LEAMINGTON SPA.
APRIL 10th, 12 noon to 10 p.m.
APRIL 11th, 10 a.m. to 5 p.m.
Schedules and particulars from the Hon. Secretary.
T. A. WESTON,
Floradale,
Orpington.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Dumfries and Galloway Gardeners' Association.

This association held its usual fortnightly meeting in St. George's Hall, Buccleuch Street, Dumfries, on the evening of March 2. Mr. S. Arnott, Sunnymead, presided over a fair attendance. After the usual formal business, which included a summary of the income and expenditure and liabilities to date, the chairman called upon Mr. J. MacDonald, Cargen Gardens, to give his paper on "The Greenhouse."

Mr. MacDonald gave an excellent paper, erring, perhaps, on the side of brevity, but an admirable and comprehensive review of his subject, and one which was much appreciated by those present. Several questions connected with the plan, construction, and arrangement of the staging, and the plants, were dealt with, and stress laid upon those the essayist considered of most importance. Following this was a concise review of the best plants for the greenhouse, in which Mr. MacDonald included the greater number of the favourite subjects of the day, with a few others not so much in vogue. The use of climbers for the decoration of the structure was recommended, and suitable plants suggested. Hanging baskets were also advocated in reasonable numbers, and plants of worth for this purpose named.

An interesting discussion followed, in the course of which other plants were suggested. The leading speakers were Messrs. Hutchinson, Joss, Murray, Hunter, Sturrock, and Nicholson. Mr. MacDonald made an excellent reply, and was accorded a hearty vote of thanks.

Chester Paxton Society.

The last of the series of lectures for the winter session took place at the Grosvenor Museum on Saturday last, when Mr. N. F. Barnes, of Eaton Gardens, delivered a highly interesting lecture, entitled "The Royal International Horticultural Exhibition of 1912: Its Object, Attainments, and Lessons." Mr. Barnes had the distinction of being appointed one of the jurors, and was an exhibitor of some competitive entries from Eaton Gardens. His lecture was the outcome of his personal experiences. Mr. J. Stubbs, of the County Asylum Gardens, presided over a large audience, composed mainly of practical horticulturists, who followed the lecturer's remarks with the closest interest.

In explaining the objects of the exhibition, the lecturer stated that prior to 1910 there had been a feeling among horticulturists that the time had come when there should be an attempt made to hold an international display on a scale that should do justice to British horticulture, and emulate, if not excel, the fine exhibitions held at Paris, Berlin, Brussels, Ghent, and Chicago. With this object in view, the Council of the R.H.S., in March, 1910, called a public meeting, and at this meeting a formal resolution was passed deciding to hold a show. The question of site presented some difficulties, which were overcome by the selection of Chelsea Hospital Grounds, the Commissioners of the Hospital (for a handsome consideration) granting the use of twenty acres of ground, which proved an almost ideal site. The early preparation of the schedule of the exhibition (which was held from May 22 to May 30) followed on, and was not so easy a task as it at first may seem. It consisted of 428 classes; divided into twelve sections and subsections.

Having outlined in brief some of the objects, the lecturer proceeded to some of the attainments by showing on the screen and describing a series of about a hundred lantern pictures.

The lecturer stated that the finest feature outside the tents was the rock gardens, and words failed him to describe the artistic effect of some of these, the only regret being that the work was only put up for a temporary period—that of eight days. Some beautiful examples of these were shown on the screen.

What were the lessons? First, that British horticulture is capable of holding its own among other nations, whether in the evolution of new and improved varieties, or in the cultivation of old types of plants, etc. Secondly, that exhibitions of this kind are a great stimulus to the craft of gardening. Thirdly, that an exhibition of this kind does not stand alone; it is related to a past and to a future; it is for certain reasons the harvest of a past seed time and the seed time for a future harvest. Fourthly, it shows there are patient workers in scientific research scattered over the field of horticulture, who were capable of even greater efforts.

In conclusion, the lecturer emphasised the importance of three things to be done. To organise, specialise, and standardise. A hearty vote of thanks was, on the proposition of Councillor Walter Welsby, supported by Mr. G. P. Miln and Mr. R. Wakefield, accorded to Mr. Barnes for his able lecture.

THE FUTURE OF THE DAHLIA.

The following is the text of the lecture delivered by Mr. Fred. G. Treseder, of Cardiff, at the recent dahlia conference:—

As dahlia lovers we have a plant which, for diversity of form, ease of cultivation, rapidity of growth, and freedom of flowering, is unequalled. We have our singles, single cactus, cactus, dwarf bedding cactus, anemone, pæony, star, decorative pompon, pompon cactus, show and fancy, as well as several other pretty distinctive sections. We all remember Juarezi appearing in 1880, and, later, a set sent out by one of our leading dahlia firms. What a marvellous improvement there is in this class to-day; such varieties as H. H. Thomas, Dr. Roy Appleton, Flora, etc., are a great advance on the older varieties. Can we hope for such improvement in the future? It depends entirely upon whatever our affections may claim. For exhibition, I see no reason why we should not obtain, even yet, greater diversity of form and colour, as each year's seedlings have proved so. We are all of one opinion in striving to obtain a sturdier race, more particularly as to freedom of bloom and rigidity of stem. Must we, however, sacrifice our exhibition varieties, many of which are, unfortunately, weak in the stem? These, however, will at all times claim their supporters among show board exhibitors and floral decorators, who are satisfied with beauty of form and colour.

The gardener must have a type we all desire for bedding. The cactus dahlia, in my opinion, with few exceptions, is too heavy in the flower, and not sufficiently free to ever become really popular for bedding. The two types must always remain distinct. If we do condemn the weak stem, which no one really likes, we shall at once do away with many beautiful forms and varieties, and we shall certainly reduce our supporters, whether amateur or professional. We all know that many working men and others spend an enormous amount of time and attention on producing blooms for the show board, and they are as critical in the selection of varieties as any first-class exhibitor. At the same time, I do not say that raisers should relax their efforts to obtain more sturdy varieties, and those which have stiff, erect flower stems.

We are badly in want of a real good bedding scarlet. Amos Perry is certainly the best we have, but what we want is a scarlet with a glowing colour of the old Gloriosa. We want varieties suitable for bedding, and more particularly for cutting purposes.

In the singles, and here I do not refer to the pæony-flowered, I do not see that we shall get much improvement. In this section, we have one good quality, that is freedom of flowering, with a wonderful range of colour, and perfection of form; a type that has great charm either for decorative use or for bedding.

These remarks will also apply to the pompons. Here we have ideal bedders, somewhat stiff, but of great decorative value. Greater length of flowering stem is certainly to be desired, but longer flower stems can be had by planting out the old roots than those from cuttings. This section will always be in demand by florists, owing to its great freedom, and more especially the lasting qualities of its flowers, and the amount of rough usage which they will withstand.

A pompon cactus, Mary, which I sent out many years ago, received an A.M. from the Royal Horticultural Society, and is an ideal type as a bedder. There is room for improvement in this section, as one must admit that this form of flower has a much lighter appearance, either when used as a bedder or for cut purposes, than the older pompons.

We have not had much experience with the anemones, but under the hand of the hybridist we are bound to obtain diversity of colour, habit, and form, here, as in other sections. The Star dahlias are admirable subjects as dwarf bedders, or for edging where latter varieties are used, but a much more ideal habit is that of the Dwarf Bedding Cactus sorts, and here I cannot see that we need wish for a more desirable form.

Of many of the bedding and decorative forms I cannot speak from first-hand experience. In the giant decorative section the flowers are too large for floral work, and the plants are not sufficiently free flowering for use as bedders. Unless well staked they are liable to damage by rough winds. One variety in the decorative section, Kaiserin Augusta Victoria, certainly gives a wonderful display of bloom, but this type is too short in the flower stem, and too regular in its habit of flowering to ever become popular with those who prefer a light and irregular habit of flowering.

It is in the pæony-flowered dahlias that the future will yield us striking improvement; here we have the ideal bedder, the flowers being practically single and semi-single, and of a charming irregular form, so different from that of other types. They have fine, stiff, rigid stems. These, when seen in their prime, are certainly one of the most striking forms, unsurpassed for effect, for cutting, bedding, or floral work. With reasonable attention this section can be had in flower in July; in the early part of August one can be sure of a very plentiful supply of flowers.

Where one has a piece of ground which, owing to the lateness of the season, or other causes, may not have been planted, and if one is desirous of making a transformation, this section, if arranged to colour, and in their respective heights, with a little design shown in the arrangement of the garden, and the ground roughly turned up, will reward one with the most striking picture it is possible to obtain in a short time, in any department of the garden. The effect is much enhanced should your dahlia garden be made in a slight hollow, in its general effect; from the higher ground, it is surprising what a wonderful picture is produced.

The collarette section, which, I remember staged in 1902 or 1903, has certainly improved since that day, and it is pleasing to

note that some of our British raisers have made vast improvement in the habit over that of our Continental raisers. We have varieties which make handsome bedders; they have wonderful long, rigid stems, which will always make them beloved for any bedding or decorative purpose. At the same time, I do not think that the future will see this section anything like so universal as the pæony-flowered class, as I believe we prefer flowers of a decided form and colour to the bizarre forms which we get in this class.

In the show and fancy section, such varieties as Arthur Rawlings, Prince of Denmark, Merton, and Mrs. Ormerod will always be useful as bedders or for decoration. The charm of these dahlias will never be realised until we get a more ideal way of exhibiting them, say half a dozen blooms in a vase in distinct colours, shown in a similar manner to that in which we see large blooms staged at our chrysanthemum shows. Have we advanced in this class? I cannot say that we have, particularly when we see such a fine old variety as Mr. Gladstone still one of the best, and most beautiful. There is no reason why the future should not give us a type with more rigid stems, and of more decided colour, particularly a good white.

Will the future give us more supporters for our favourite flower? Yes, it will; particularly so if growers, when selecting their favourites at exhibitions, would state whether the flowers are wanted for exhibition or for bedding. The majority, in selecting varieties, believe that they will obtain a plant of good habit, and which will produce a flower like that which they have in their mind's eye at the time of purchase. Disappointment more than often follows, with the result that the plant does not get such a good name as we would desire. Information by practical men is freely given, but is not acted upon, except on rare occasions.

Can we influence those in public gardens to give the dahlia greater prominence than heretofore? There is no flower which gives us such a remarkable change in the tints of its flowers from the early blooms to that of late autumn; in fact, the shades of colour during the months of October and November are quite distinctive to those of August and September.

For house decoration in any form we shall see the dahlia more frequently used in the future; owing to the varied range in the shades of colour, it is possible to please the most fastidious. How much longer the flowers would last (foliage also if cut separately), if a little more thought were given as to the time of cutting, viz., early morning! When cut, stand them in water in any cool place until wanted. The dahlia, when associated with autumn foliage, is very effective. In no flower can we find such a range of delicate shades of colour as that which will be found in the dahlia.

It would be as well if we had annual tests of the various sections; we should then have varieties impartially judged, and the public would get first-hand information, and would be more inclinel to go in for dahlia culture.

The future of the dahlia no one can foretell. If we take into account the great number of seedlings which have been staged each year, there seems no reason why we should not obtain types which will at all times find favour in someone's sight, and wil always be found suitable either as bedders or for exhibition or floral art.

Annuals.—Many annuals can now be sown in the open ground, but where the soil is heavy and lays cold it is advisable to defer this operation for a week or so still. In preparing the ground care should be taken to work it into a fine condition, so that the seeds can be covered by lightly raking over the surface; should the ground be retentive, use fine light soil when preparing for sowing, and also for covering the seeds. Watering will be necessary should the ground become dry while the seed is germinating.—T. B. Field, Wych Cross Place Gardens.

NEW BOOKS.

CULTURE OF VEGETABLES AND FLOWERS.

By Sutton and Sons. (Simpkin, Marshall, Hamilton, Kent, and Co., Lim., London.) Price 5s. net.

Several times during the past twenty years it has been a pleasure as well as a duty to refer in appreciative terms to the excellent work by Messrs. Sutton and Sons on the cultivation of vegetables and flowers, but on no occasion has the warmest expression of praise been more highly deserved than now. The book has reached its fifteenth edition, and this should be a sufficient proof that its merits are recognised, and that practical expression has been given to this recognition, by those who are in need of the information it contains adding it to their library. Brightly written and thoroughly sound, the book at once became popular, and this popularity has been increased by the several editions that have been issued. This increase is explained by the fact that the authors have been careful to subject each edition to so thorough a revision that it has been practically a new work, but more perfect than any new work well could be. The book is so well known that there is no occasion to refer to its contents in detail, but special reference may well be made to the chapters on the rotation of crops in the kitchen garden, the chemistry of garden crops, and the making of lawns and tennis grounds from seeds, for they are not less remarkable for their interest than for the information they contain on these practical details of garden management.

THE WELSH DAFFODIL.

By W. Davis. (W. Davis, Doneraile, Exmouth.) Price 2s.

On the occasion of the installation of Prince Edward as Prince of Wales at Carnarvon Castle in July of last year, the daffodil was adopted as the floral emblem of Wales. As a consequence of the high position thus given the flower, Mr. Davis undertook the task of explaining how the Tenby daffodil (Narcissus obvallaris) first came to Wales, and for this purpose the book, which consists of ten pages, has been published.

PLANT DISEASES.

By Dr. Werner F. Bruck. (Blackie and Son, 50, Old Bailey, London.) Price 2s. net.

During the past quarter of a century much attention has been devoted to the investigation of plant diseases, and as the result some new forms of diseases have been brought to light, and an immense amount of information relating thereto has been published. In the study of the various forms of disease to which plant life is subject, they have been regarded from quite different points of view, some investigators chiefly concerning themselves with systematic descriptions, while others have directed their attention specially to devising remedies that may be readily applied by cultivators. Each set of investigators have rendered good service. It is, however, necessary to take a greater breadth of view in the study of plant diseases, and to carefully consider atmospheric influences, and the chemical composition and the physical condition of the soil, for, as the author states, they are of the greatest significance in the development of diseases. Since the beginning of the present century much attention has been given to the investigation of the conditions which predispose plants to disease, and the inclusion of the results that have been obtained greatly enhances the value of the book to the cultivator.

The diseases to which the chief cultivated plants grown in the garden and on the farm are liable are passed under review, and the progress of development of the numerous forms, and the results that follow attacks are concisely and clearly stated. The information that is given in the reference to the several diseases is indeed such that the cultivator who has carefully read the book will not have much difficulty in recognising the enemy which he has to combat, or in having a clear idea as to the best means of warding off an attack. While scientific, both in plan and execution, the book is written in a clear and pleasant style, and will be found of much value as an introduction to the study of the all-important question of diseases of plant life. On the other hand, those who may not desire to do more than obtain an elementary knowledge of the subject will find it most useful.

OBITUARY.

LADY DOROTHY NEVILL.

Within a few days of her eighty-seventh birthday, Lady Dorothy Nevill passed away on Easter Monday, full of years and of honour. A foremost figure in society for half a century, she made friends on every side, and to her house in Charles Street, Berkeley Square, there came all who occupied high positions in social life, politics, art, finance, science, and letters. Her three volumes of "Reminiscences," published a few years ago, show how intimate she was with all the notable people of the Victorian era, and prove beyond all else what a gracious and witty lady she herself was. She took a lively interest in horticulture, and until lately she was a frequent visitor at the fortnightly meetings of the Royal Horticultural Society. Indeed, horticulture, botany, and the fine arts were her hobbies. At Dangstein, near Midhurst, in West Sussex, she created a beautiful garden, and, among other things, grew orchids and tropical plants successfully. The latter included nepenthes, crotons, economic plants; and the former contained anæctochilus, and a fine range of species. Even as far back as 1874 the Dangstein collection of rare plants was regarded as one of the finest in cultivation. In 1879 Dangstein estate was broken up, and the orchids were sold; and it is of interest to notice that at the sale Cattleya labiata vera realised from £10 to £30; Masdevallia tovarensis, £13; Sobralia macrantha, from £11 to £13; Angræcum caudatum, £15; Masdevallia Estradæ, £9 10s.; and Dendrobium Griffithianum, £16.

MR. F. G. HEATH.

We record with regret the death of Mr. Francis George Heath, whose works on ferns and sylviculture are well known, which occurred at Weymouth on the 21st inst., in his seventieth year.

Mr. Heath, who was a native of Totnes, entered the Civil Service in 1862, and attained to the position of a surveyor in the Customs Outdoor Department, from which he retired in 1904. Many years since he began to take a keen interest in open spaces and the countryside, and between that period and the close of his active life he did good service in connection with the movement for securing open spaces for town dwellers, and wrote many books on ferns, trees, etc. He specially interested himself in securing Burnham Beeches and Epping Forest as open spaces, and in enlarging Victoria Park. Chief among his books were "The Fern Paradise," "The Fern World," "Our Woodland Trees," and "Sylvan Spring." He also edited a new edition of Gilpin's "Forest Scenery."

Hyacinth Starlight. — This hyacinth, shown at a recent meeting of the Royal Horticultural Society, merits a note by reason of its distinct appearance. The flower spike is long, and rather narrower than in many other varieties, while in colour the blossoms are of a deep rich blue, with a conspicuous star-like centre of pure white. At a little distance, the flower spike bears a great resemblance to a delphinium, such as the Rev. E. Lascelles. The hyacinth in question is certainly a decided departure from the forms generally grown, and in a group it at once attracts attention.—W. T.

"ROSES AND THEIR CULTIVATION." A new edition of this Standard Book is now ready, and every Rose Grower should secure a copy. Cloth, many illustrations, 2s. 10d., post free, from Publisher, 149, Aldersgate Street, London, E.C.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

R.H.S. EXAMINATION.—W. E., Cheshire: Will you kindly give me information concerning the ordinary examination of the Royal Horticultural Society, i.e., the date of the examination, etc.?—When your communication arrived it was already too late for you to enter for the R.H.S. examination, which is to be held on April 2. We would have written or telegraphed had there been a chance for you to enter. The regulations (previously published in our columns) are that—"County Councils, lecturers, etc., must send in to the Society the names and addresses of candidates at least fourteen days before the examination takes place. They must at the same time send a cheque at the rate of 5s. a head, otherwise the entries cannot be received. No entry fees can be returned. Gardeners and students wishing to sit for the examination, who have not attended any particular series of lectures, must send in their name and address, and also the name and address of some responsible person willing to conduct the examination to the Secretary, R.H.S., Vincent Square, Westminster, at least three weeks before the date of examination. The Society is willing to hold the general examination and school teacher's examination wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations w consent to supervise one on the Society's behalf, and in accordance with the rules laid down for its conduct." You can obtain the complete list of questions set at all the R.H.S. examinations from 1893 to 1912, in book form, for 2s., on application to the Secretary, R.H.S., Vincent Square, Westminster, and we advise you to obtain the list, as it will indicate the range of the examination.

POOR ASPARAGUS BEDS.—F. G., Shiplake: Could you please tell me if the soil, of which I send sample, is suitable for asparagus culture? The beds are raised, and have been planted upwards of twenty years. The flavour of the asparagus is all that could be desired, but the heads come so very thin every year. My employer tells me the crop has never been strong, though every encouragement has been given. I am of opinion that the drainage is at fault.—The soil is not of the best, but if the crop is well fed there seems no good reason why excellent produce should not be obtained from the beds. It is possible that the lower soil is not in so good a condition, but this you can ascertain by taking out a deep trench at one end of the beds. As the beds have never been a great success it would be a good plan to at once set about the preparation of new beds that would eventually take the place of the old ones. You would then make sure of efficient drainage, and add to the staple soil an equal bulk made up of decayed manure, flaky leaf soil, turfy loam, or turf trimmings, and some sea sand. We may add that it is really wonderful how much can be done to improve asparagus beds by the use of nitrate of soda or salt in early spring, and the free use of liquid manure as soon as cutting ceases for the season. The application of heavy mulches of wet manure in early winter is seldom a good plan, but anything that tends to encourage strong growth after cutting ceases will also tend to the production of strong crown buds that will yield stout, succulent heads another season. It is a great mistake to cut asparagus too severely, and it is a further mistake to allow seedlings to grow in permanent beds.

SHRUBBY VERONICAS.—E. T., Birkenhead: Will you please inform me when is the best time to cut back the shrubby veronicas, such as V. Traversi, V. cupressoides, etc.?—Veronica Traversi may be cut back in spring or immediately after it has flowered; if the plants are at all straggly the pruning had better be done at once. V. cupressoides so seldom grows more than a foot or so in height that it rarely needs any pruning beyond the removal of a few growths that may exceed the allotted space. All the sturdier shrubby kinds may be treated as suggested for V. Traversi if they have become ill-shapen. It is a good plan to put in a few cuttings in late summer, inserting these in sandy soil in a frame; these root readily, and, if protected from frost during the winter, they will be ready to plant out the following spring.

GREENHOUSE FLOWERING PLANTS FOR THE SUMMER SEASON.—E. T., Prenton: Please oblige me with a list of good flowering plants for providing a succession of bloom from May to September. These are needed for a cold greenhouse, and should be kinds that can be raised from seeds.—This seems, at first sight, a very simple question, but to answer it with any degree of fulness would occupy a large amount of space. Many plants that may be, and are, flowered in a cold greenhouse are raised in a warm house or pit; therefore a little heat is necessary if full advantage is to be taken of the many beautiful plants available. Further, one or two cold frames are essential to a continuous display. As for the greenhouse itself, a small heating apparatus sufficient to keep out frost would prove of immense service. We commend to your consideration the various articles on greenhouse plants that appear in our columns; and also the calendar notes, under "Work for the Week," dealing with the greenhouse and conservatory. We would also suggest that you obtain "The Amateur's Greenhouse" (Gardeners' Magazine office, 148-9, Aldersgate Street, E.C.; post free, 5s. 6d.), as you would find it very helpful. Dealing more directly with the question, Primula obconica is a host in itself, and practically perpetual flowering; one or two batches of plants should be raised every year, in spring and in late summer. For Chinese primulas and begonias you have not sufficient warmth, though the latter might be sown in May, and if the seedlings did not flower much the same year they would give tubers which would start into growth the following spring. Sow calceolarias in May and June, to flower the following summer; they must be kept free from frost during winter. Treat cinerarias similarly, to flower the following spring and early summer. Sow clarkias in September in pots, and grow them in a cool frame, bringing them into the greenhouse in early spring to flower in May and June. You will have to depend largely upon such annuals as chrysanthemums of the segetum type, Collinsia bicolor, Phlox Drummondi, petunias, and asters for flowers; the latter may be planted out, and lifted and potted in August. Do not despise forget-me-nots for spring flowering. Sow schizanthuses in March, and again in August, to secure a succession. Sow intermediate stocks in March or April for autumn flowering, and in August for spring flowering. Canterbury Bells and Chimney Campanulas must not be omitted; they can be wintered in a cold frame. Here, then, are a few subjects that, if carefully attended to, would provide flowers during the period indicated, especially if two or more small sowings were made of clarkias, collinsias, mignonette, etc. As already stated, given a little artificial heat, and no objection to plants raised from cuttings, the greenhouse could be kept gay with greater ease and certainty from spring to autumn.

LAND INFESTED WITH YELLOW RATTLE.—R.H.B., Gloucestershire: In addition to the charge of the garden, I have the management of the home farm, and growing on some parts of the arable land is a yellow weed which has greatly perplexed me. It appears to be injurious to the cereals that we grow, for where the weed is prevalent the crop of corn is unsatisfactory. I have no doubt that, with the aid of the dried specimen sent herewith, you will be able to give me the name of the weed, and whether it is hurtful to the cereal crops. I would mention that the plant bears yellow flowers, and that these are followed by large seed pods in which the seeds become loose when ripe, and make a rattling noise when the flower-spike is shaken.—The dried specimen that you have sent is much appreciated, because it enables us to recognise the species at once, and give you the information you require. The plant is Rhinanthus major, and is commonly known as the Yellow Rattle. There can be no doubt whatever that it is injurious to cereal crops grown on land that is infested with the weed, and that it is the cause of some portions of your crops being less satisfactory than you could wish. The Yellow Rattle is parasitic on certain of the cereals, and also on some of the composite and umbelliferous plants, and instead of obtaining its food from the soil by means of its roots, it becomes attached to the roots of its host plant by means of organs that are commonly designated as "suckers." The roots of host and parasite spread through the soil, and when they come into contact pad-like swellings are developed on the roots of the latter, and the outer cells of these lengthen and penetrate the tissues of the host plant. When the Yellow Rattle has become established it draws its food supplies from its host, and so impoverishes it as to prevent satisfactory development. Owing to the Yellow Rattle being attached to the cereal plants, it cannot be eradicated by the usual methods of dealing with weeds. The best method of procedure where the land is badly infested is to allow the ground to remain fallow for one year, and plough it two or three times, and in the year following take off a root crop. If you act upon this suggestion your fields will be free from the weed in two years.

NAMES OF PLANTS.

R. B. A., Bedford.—A garden-raised variety of Phyllocactus.

E. G., Teignmouth.—1, Isolepis gracilis; 2, Epidendrum variegatum; 3, Cattleya Schroderæ.

A. D. N., Chesterfield.—1, Adonis amurensis; 2, Saxifraga Burseriana; 3, Anemone blanda; 4, Prunus divaricata.

M. E. J., Dorking.—1, Acalypha Macafeeana; 2, Acacia Drummondi; 3, a cypripedium, not recognised, evidently of C. Leeanum parentage.

F. W., Wolverhampton.—1, Boronia megastigma; 2, Saintpaulia ionantha; 3, Pelargonium Mrs. Pollock; 4, Cyperus alternifolius variegatus; 5, Irisene Herbsti.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,

London, E.C.,

who will give the matter immediate attention.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

Be sure and purchase "Twentieth Century Gardening," by John Weathers. 300 pages. 1/- nett. To be obtained of all Booksellers.

Full particulars from
THE
CHEMICAL UNION, Ltd, IPSWICH.

GARDENING ENGAGEMENTS.

Mr. H. Burson has succeeded the late Mr. William Bennett as head gardener at Rangemore, Burton-on-Trent, the seat of the Dowager Lady Burton.

Mr. H. Fishenden, general foreman at Billown Gardens, Castletown, has been appointed head gardener to C. C. Black, Esq., Cranham Holme, Upminster.

COMING EVENTS

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.

Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.

Ealing Horticultural Society, July 9.

Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.

Thornton Rose and Sweet Pea Show, July 18.

Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.

Tunbridge Wells Flower Show, July 23 and 24.

St. Quintin Horticultural Society, July 24, in the Gun Club grounds, Wood Lane, W.

City of London Rose Show, July 26, at Cannon Street Hotel.

Perth Horticultural Society, July 30.

Datchet Horticultural Society, August 4, at The Lawn.

Coventry Flower Show, August 4.

Seamoor Floral and Horticultural Society, Aug. 4.

Swanage Horticultural Society, August 4.

Westbury Horticultural Society, August 6.

CATALOGUES RECEIVED.

R. A. LISTER AND CO., LIM., DURSLEY.—This firm makes a speciality of tubs for palms and shrubs. Oak and teak are the materials used, with brass hoops. The range of pattern is very considerable, and most of the patterns are illustrated.

VILMORIN, ANDRIEUX, AND CO., PARIS.—The plant catalogue just received covers a particularly wide field; many novelties, including Chinese plants, are listed, and the dahlia and chrysanthemum lists are especially full; in connection with the latter, the varieties are grouped according to colour, time of flowering, and style of flower, as well as in alphabetical order.

L. REYMOND, VILLEURBANNE, LYONS.—In this catalogue a large number of the newer continental roses are described in English. The varieties are placed in their respective groups, and a full index facilitates reference.

NEWS FROM HEADQUARTERS.

THE SECRET OF BEAUTIFUL LAWNS.

An American, "The Practical Greenkeeper" tells us, was struck with admiration of the really wonderful lawns at the Universities. Hoping to pick up a wrinkle or two, he asked one of the gardeners how it was done. The gardener replied, "They rolled 'em and mowed 'em and mowed 'em and rolled 'em for 300 years."

But that was only half the truth. "They" certainly "weeded 'em and top-dressed 'em" for the same period, for without that no lawn can be brought to a state of such perfection.

A perfect lawn is "a thing of beauty and a joy for ever," the ideal setting for cottage and mansion, and the pride of the possessor of a perfectly-kept lawn is decidedly pardonable.

Now, of all seasons of the year, time spent on the renovation of worn or poor turf and overlooking lawns is sure of a liberal reward later in the year. Mow the lawn with a mowing machine, cutting the grass as short as possible, dress the lawn or green with Carters Complete Grass Manure, at the rate of 2oz. per square yard, then rake and cross rake the surface with an iron-toothed rake so as to work in the manure, and thoroughly open up the surface soil.

"The Practical Greenkeeper," published by James Carter and Co., Seedsmen to His Majesty the King, deals with the care of the lawn, golf courses, cricket fields, and the like, in a manner that is as simple and interesting as it is thorough. This fine 100-paged book is published free, and a copy will be sent to anyone interested upon application to

JAMES CARTER & CO.,
Seedsmen to H.M. the King,
Raynes Park,
LONDON, S.W.

Situations Wanted—*continued.*

MR. W. GREENTREE recommends YOUNG MAN as Single-handed Gardener; 10 years' experience; good references; willing and obliging. Hawley House Gardens, Blackwater, Hants.

NURSERYMEN.—GARDENER, knowledge Inside and Out; good grower; Ornamental Planting, Landscape, Jobbing, etc. BEGLIE, 22, Sadler Street, Mansfield, Notts.

JOURNEYMAN (First), age 20, seeks Re-engagement; Fruit and Plant Houses; good references; well recommended; Bothy preferred; nearly three years present place. J. EDWARDS, 2, Lake Cottages, Witley Park, Milford, Surrey.

JOURNEYMAN, Kitchen Garden and Pleasure Ground; age 21; good references. R. SCUTT, 14, Park End, Bromley, Kent.

YOUTH (17) seeks SITUATION in private Garden under another Gardener, Highgate or Hampstead district preferred. W., 13, Cochrane Street, St. John's Wood.

Situations Vacant.

UNDER-GARDENER required for Nursery Grounds in Midlands, good at Herbaceous and Propagating. Chiefly outside. State age, experience and salary required, by letter only to WEBB and SONS, Royal Seedsmen, Wordsley, Stourbridge.

WANTED, a YOUNG MAN, age from 24 to 30, experienced in Pleasure Ground, Kitchen Garden, general routine of gardening; wages 18s. per week. nApply, HEAD GARDENER, Bursledon Towers, Southampton.

WANTED, Experienced YOUNG MAN for garden, also little housework; age about 20; wages, 18s. a week; letters only. G. R., The Lodge, Redroofs, Broom Road, Teddington, Middlesex.

WANTED, Strong Active SINGLE MAN to look after, and do work with garden horse, fill up time in garden; one who is willing to make himself useful, and also understands the usual work in a private garden; Sunday duty in turn; no Bothy. Full particulars to E. SMITH, Falcon Wood, Shooter's Hill, S.E.

VOL. LVI.—No. 3,101. SATURDAY, APRIL 5, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Glass Shelter in the Garden.

For a long series of years subsequent to the use of glass becoming general in gardens as a consequence of the cheapening of the cost of manufacture, the predominant desire of the majority of those who were actively engaged in garden management was the possession of structures equipped with a well-devised system of heating by hot water. So strong was this desire that, in most cases, when the question was under discussion of providing additional glass accommodation for ornamental plants or fruits, it was contended that glass structures should invariably be fitted with a heating apparatus, because of their utility being increased nearly, if not quite, a hundredfold thereby. It was further suggested by many that a heated structure should be of dimensions that would admit of the occupants receiving the attention they required from the inside, and thus obviate the risk of injury from the cold air to which they are necessarily exposed when the lights are raised or drawn off to allow the watering, training, and other details to be carried out from the outside. Hence it was that for a considerable period comparatively few pits and frames were included, even in comprehensive schemes, for the cultivation of plants under glass. As a consequence, when the turf pit, so fully utilised by past generations of cultivators, and other makeshift shelters, had gradually, but surely, disappeared, frame accommodation became so limited as to greatly increase the difficulties of maintaining successional supplies of various kinds. Unquestionably pits and frames, as in the case of glasshouses, have their utility appreciably increased by their being in direct connection with a hot-water boiler; and it is equally true that the work of the garden is assisted by an area of heated pits. While these two points are indisputable, it does not necessarily follow that the whole of the pits and frames should be heated. It was not necessary, or desirable, in the early days of hothouse building on a large scale, and it is certainly not so at the present time. Then the greater proportion of the plants grown for garden decoration, as well as for other purposes, were more or less tender, and required artificial heat at certain stages for their successful cultivation, and early vegetables and spring salads were not extensively grown. Now the greater proportion of the plants grown for beautifying the flower garden, apart from those occupying the herbaceous border, are hardy, or nearly so, and there is a strong demand both for early vegetables and salads. From thirty to fifty years ago it may have been a convenience to have had the greater number of the pits heated, as thereby the thousands of bedding plants, as they came from the warm houses in which they had passed through the

MR. ARTHUR J. COBB.

initial stage, could be placed in them without risk of injury from a sudden drop in the temperature, and be kept safe from frost with no more covering than mats laid singly on the glass. It is probable that even in these days a few lengths of unheated frames would have been an immense advantage. At the present time they are a necessity, and, in the majority of gardens, the accommodation they afford falls short of the requirements of the case. It will be an advantage to have a certain proportion of these shelters heated, but the service of pipes and boiler adds so materially to the cost of pits and frames that they need not be provided unless there will be occasion for their use over the greater part of the year. Concurrently with a large and rapid extension in the cultivation of hardy flowers there has been an increased demand for the accommodation afforded by unheated shelters, and, in not a few gardens, an endeavour has been made to provide space proportionate to requirements. The necessity for the increase in the glass shelter is explained by the fact that where hardy plants are successfully cultivated young plants of a number of kinds have to be annually raised from seeds and cuttings, and that the greater proportion derive some benefit when kept in a freely-ventilated cool frame during the first winter. Consequently space is required during the summer months for rooting cuttings and raising seedlings, and nursing the young plants through the first stage of growth, and, in the winter, for the accommodation of such plants as may suffer from the inclemency of the weather if planted in their permanent quarters, this risk being the greatest where the soil is close in texture and retentive of moisture. A considerable area of frame room is also essential in gardens where there is a rockery of some size, and the choicest of the alpines are grown. Some of these suffer during the winter from the high degree of humidity in the atmosphere, others from heavy rains, and not a few are liable to injury from slugs when commencing to make new growth early in the year. Therefore, unless there is a reserve of young plants safely sheltered in the unheated frame there will be a difficulty in maintaining the ledges and slopes of the rockery in a flowery state, and in ensuring the proper representation of the less robust kinds. Moreover, in gardens where there is no rockery for the cultivation of the flowers of the Alps, a goodly number of kinds of great beauty might, with the aid of a few unheated frames, and a small span-roof house of an inexpensive character, be grown with great success, and their charms, more especially of the earlier-flowering kinds, be enjoyed under the most favourable conditions. To the value of the cold frame in the preparation of the hardy and half-hardy annuals, and other plants for the embellishment of the flower garden during the summer months there is no occasion to refer except to say that they should, as far as practicable, be equal to the requirements, because of the desirability of avoiding overcrowding during the preparatory stages. The utility of unheated frames is by no means limited to the service they are able to render in so many ways in the

flower garden. They are equally useful in the kitchen garden, and their value cannot well be overestimated as aids in the maintenance of a supply of salading from late in autumn until the spring is well advanced, and in the production of supplies of early vegetables. So far these accessories have been referred to in generic terms, but, as so well known, there are many forms of these, and especially useful are the span-roof frames, which can be obtained with wooden sides and complete in themselves, or with a framework to rest on walls, of varying heights. These frames may be had of various lengths and widths, and are superior to the ordinary garden frames, because of the fuller exposure to light and air they afford their occupants. The sizes are, of course, selected according to the purpose for which they are required, and if they are to be moved about for the protection of various subjects in different positions, those having sides of wood are selected because of their lightness. In addition to the several garden frames there are numerous protectors, of varying shape and size, that are useful for placing over single plants or small colonies, and these should be taken full advantage of. With an available supply of these, vegetable marrows, tomatoes, early cauliflowers, and other vegetables can be planted out a week or two in advance of the usual time, and with the shelter they afford the growth is so greatly accelerated as to make a difference of two or three weeks in the time they are ready for sending to the table. Glass has such remarkable power in sheltering vegetation from cold and wet, and of collecting warmth about the plants for which it is used as a covering, that we would suggest that its peculiarities be carefully studied, and its protective properties fully utilised.

Mr. Arthur J. Cobb, whose articles on dahlias have recently appeared in our columns, is head gardener at Duffryn, near Cardiff, where R. A. Cory, Esq., has a most charming garden, and cultivates the largest private collection of dahlias to be found in this country. Mr. Cobb commenced his gardening career as a boy at Cirencester House, where, under Mr. T. Arnold, he spent ten years in the various departments. For several years he was first journeyman there, and when he left it was to become foreman at Poulton Priory, Fairford. After two years' experience he entered a London nursery, and presently passed on to become foreman at Hartpury House — recently described and illustrated in our pages. Four years later he was invited to take charge of the Duffryn Gardens, where he has now been about six years, and during that period great alterations and extensions have been made, both Mr. and Miss Cory being keen gardeners. At Duffryn there are particularly fine collections of nymphæas, herbaceous plants, succulents, and the newer trees and shrubs. There are thousands of roses, including all the Wichuraiana varieties; while summer bedding plants and the dahlias are great features. The latter are grouped in a slightly-hollowed space, and, under Mr. Cobb's method of cultivation, they commence to bloom in July, and provide a dazzling display in August and September, and on until the frosts come. Mr. Cobb has also raised large numbers of hippeastrums from the finest named varieties, and the Duffryn collection of these glorious flowers numbers over a thousand flowering bulbs. Both Mr. Cory and Mr. Cobb are enthusiasts, and, given health and strength, they will place Duffryn in the front rank of British gardens.

Guide for Kew.—In another part of this issue we refer in detail to the arrangements now made for the conduct of parties of visitors through various parts of the Royal Gardens, Kew. Mr. S. T. Dunn, M.A., F.L.S., formerly at Hongkong, appears to be the appointed guide, as he conducted the first party, of three, on the morning of April 1.

London Daffodil Show.—Unless very warm weather occurs during the next ten days or so, there is likely to be a very interesting exhibition of daffodils at the Royal Horticultural Hall, Westminster, on Tuesday and Wednesday, April 15 and 16. The daffodil season is an early one again this year, but the dull and cool weather of late has steadied the flowers. The London Show is arranged by a sub-committee of the R.H.S. Narcissus and Tulip Committee, and, while the Royal Horticultural Society gives cups and medals, the cash prizes are raised by subscription. If everyone interested in this show competes, there will be a goodly display both of well-known varieties and new seedlings. We may remind readers that the daffodil schedule is included in the R.H.S. "Book of Arrangements."

The King's Cup for Roses.—The King has presented a silver challenge cup to the Windsor Rose Society to replace King Edward's Cup, which was won outright last year. The new challenge cup will be offered under different conditions to the trophy which preceded it, and will be held only from year to year, and cannot be won outright. His Majesty has also sent an annual subscription of £5 to the society, and has given permission for the exhibition to be held on the slopes of Windsor Castle, the date fixed being June 28.

Weather and Vegetation at Glasgow.—We have much pleasure in acknowledging the report by Mr. James Whitton, V.M.H., Superintendent of Parks and Curator of Botanic Gardens, Glasgow, on the weather during 1912, and its effects on vegetation in the open spaces under his control, for, as usual, it is of much interest. In the summary of the records of the twelve months Mr. Whitton observes: "In comparing the records of the year with those of its predecessor, we find a sharp contrast between them as to the weather conditions in favour of 1911. That year was generally fine and 'ideal' for these latitudes, whereas 1912 was conspicuous for heavy rainfall and low temperature, with a marked absence of brilliant sunshine. The earlier part was the best and driest, April and May being the sunniest also. Consequent on the well-ripened condition of growths on trees and shrubs, vegetation readily responded to the quickening agencies of Nature's forces. The storm on April 8 damaged the young growths on the earlier leafing trees and shrubs, and the frost on the 12th of the same month spoiled the bloom on the early-flowering rhododendrons. Apart from these mishaps, the development of growth and flower afterwards was extremely satisfactory. The bloom on most of the ordinary hardy plants was above the average, plums, cherries, pears, apples, laburnums, lilacs, hawthorns, ribes, rhododendrons, etc., being specially fine. With the rains in June vegetation made rapid headway, and the development of growth was somewhat remarkable on many species of trees. Unfortunately the wet, sunless weather was prolonged, with the result that much of the fine growth was indifferently ripened. The great bulk of hardy trees and shrubs have not set flower buds freely, so that a great display of bloom in the woodlands cannot be expected this season.

Primula Conference.—A Primula Conference will be held in the Lecture Room at the Royal Horticultural Hall, Vincent Square, Westminster, on April 16, when the chair will be occupied by Sir John Llewelyn, Bart. The conference will open at 11 o'clock, and will close at about 4 p.m., with an hour for luncheon at 1, which will be served in the Committee Room (2s. 6d.). The following are the papers to be given: Morning session—(1) "European Primulas," by Dr. John McWatt; (2) "European Hybrids in Nature," by Mr. R. Farrer; (3) "Himalayan Primulas," by Mr. W. W. Craib. Afternoon session—(4) "Chinese Species of Primula," by Professor Bayley Balfour, F.R.S.; (5) "Primulas from a Garden Point of View," Miss Jekyll.

Testimonial to Mr. A. Mackenzie.—The retirement of Mr. Alexander Mackenzie from the position of manager of Messrs. Methven and Sons' Warriston Nurseries, Edinburgh, which he has held during the past forty-five years, has been thought by many horticultural and personal friends a suitable occasion for presenting him with a tangible token of their esteem. It is also desired to recognise the great services Mr. Mackenzie has rendered to horticulture during his gardening career. He was one of the originators of the Scottish Horticultural Association, and as a member of council and for many years hon. treasurer he contributed liberally to the success that has been achieved by the association. A committee has been formed for the purpose of carrying out the project, with Mr. David King, president of the Scottish Horticultural Association, as chairman; Mr. J. Phillips, Granton Road Nurseries, Edinburgh, treasurer, and Mr. M. Todd, 31, Shandwick Place, Edinburgh, secretary.

Mr. Mayne, the hon. secretary of the Cardiff Gardeners' Association, was, on the occasion of the annual meeting held the other evening, presented with a gold watch and a purse of gold in recognition of the services he has rendered the association during the four years he has occupied his present position. We congratulate both the recipient and the subscribers to the testimonial fund.

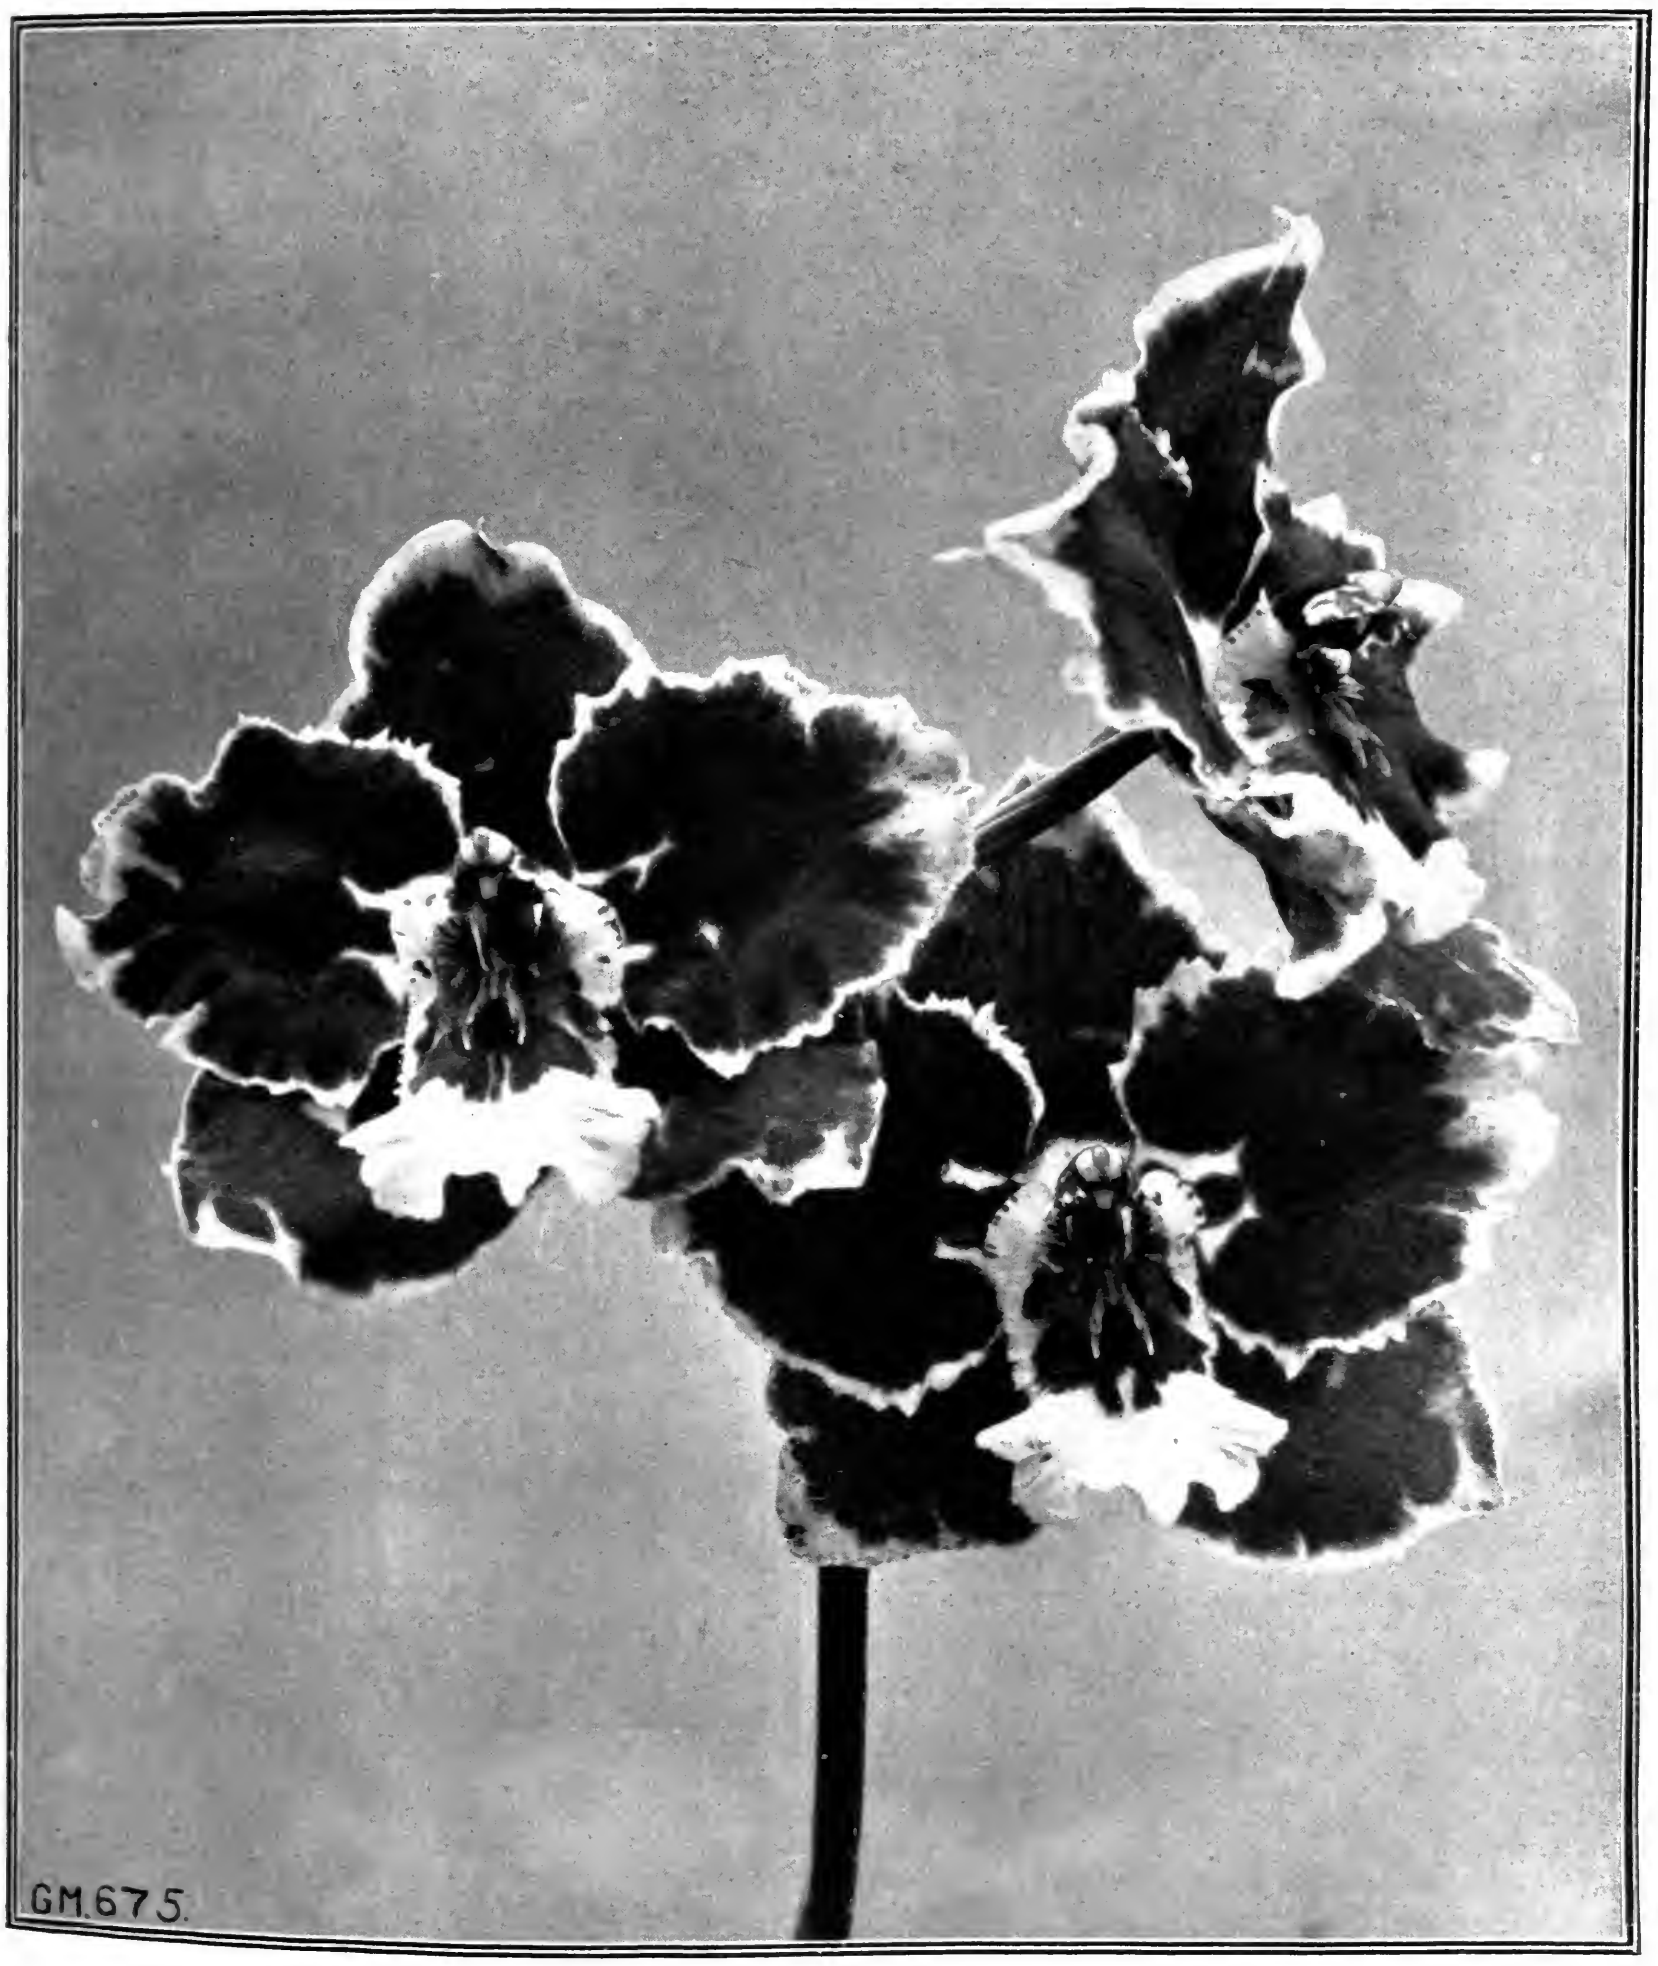
Carnation Carnival at Leamington.—The Perpetual-flowering Carnation Society, which holds its first provincial show at Leamington on April 10 and 11, has made arrangements with the Great Western and London and North-Western Railway Companies for the issue of cheap tickets on the show dates from all stations within a thirty-miles radius of Leamington. These tickets are available by any train starting before 12 noon, but can only be used for the return journey on the date of issue. These tickets will be issued at a single fare and a-third. Visitors from London and the South may obtain tourist tickets to Leamington either at Paddington, Euston, or from Messrs. T. Cook and Sons, at 13s. 9d., third class return. A number of trains from Paddington reach Leamington in one and a-half hours.

United Horticultural Benefit and Provident Society.—The annual meeting of this society will be held at the Royal Horticultural Hall, on Monday, April 14, at 8 p.m., when Mr. Charles H. Curtis will preside. It is hoped that all members who are living near London will endeavour to be present.

ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.

Daffodils were the flowers most in evidence at the Royal Horticultural Hall, Westminster on April 1, their bright blooms and sweet fragrance made the hall a gay spring-like scene. Rockery displays were quite good, indeed, they were far above the average of quality, and Mr. Beckett's display was the crowning feature. Orchids, carnations, greenhouse plants, and roses were the other leading subjects. Visitors were numerous, and throughout the greater part of the day the weather was bright and pleasant.

The daffodil lovers had a field day, and the large number of exquisitely beautiful new seedlings staged proved very tempting, as we gathered from the happy faces and jovial remarks of the raisers and growers that excellent business was done in these new creations. Everyone was glad to hear that Mr. Bowles, chairman of the Daffodil and Scientific Committees was recovering from his illness, and there were many expressions of regret at the loss of Mr. Andrew Kingsmill, whose death on Saturday last removes one of the oldest members from the Daffodil Committee.



ODONTOGLOSSUM EXIMIUM WARNHAM COURT VARIETY.
Flowers marked with deep crimson-purple on a blush ground. F.C.C., R.H.S., April 1
C. J. Lucas, Esq., Warnham Court, Horsham.

FLORAL COMMITTEE.

The finest rock garden exhibit yet seen in the hall was put up on this occasion by Mr. Edwin Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree. The space occupied was about 40ft. by 8ft. 6in., and this was grandly filled. Altogether about a dozen tons of mountain limestone, all finely weathered, were used in the production. In the centre was a flat, boggy area, with water dripping into it from the rocky wall at the back, and from one end a ravine cut back into the bank, and here nestled a colony of Primula denticulata. In the bog were Primula frondosa (about a hundred dainty little plants), with Ranunculus montanus, Caltha palustris, Solomon's seal, etc., in the wettest part. Overhead were ferns in the moist rock crannies, and right on top were berberis, mollis azaleas, and conifers of sorts. To the left the bold rock front gave shelter to colonies of aubrietias, primroses, violas, cytissus, kalmias, daphnes, veronicas, and a large plant of the gnarled and quaint Corylus avellana contorta. To the right of the boggy portion Cotoneaster Dammeri trailed over the rocks studded with scarlet berries. Farther along on the slopes were masses of Erica carnea, Primula denticulata, P. frondosa, the Golden Cytisus Beani, Primula viscosa Mrs. J. H. Wilson, and a tall, graceful plant of Cotoneaster salicifolia floccosa. This was a splendid effort, especially from a private establishment,

and it won general admiration and a gold medal.

Messrs. T. S. Ware, Feltham, planted fine colonies of Primula rosea, P. denticulata alba, Ranunculus amplexicaule, Soldanel a alpina, Gentiana acaulis, Aubrietia Perkini, and other delightful alpines, on a low rock garden. From the Guildford Hardy Plant Company, Guildford, came a collection of alpine primulas, that included the bluish-purple P. calycina; saxifragas, anemones, violas, scillas, etc. Miss Dixon, Edenbridge, staged primroses and polyanthuses.

Messrs. G. and A. Clark, Dover, arranged a little garden with beds and borders of splendid polyanthuses and coloured primroses. The background was formed of a rockery bank, faced with heaths, aubrietias, and primroses, and topped with small conifers. Mr. G. Reuthe, Keston, exhibited beautiful masses of Himalayan rhododendrons, a selection of saxifragas, and primulas, and examples of Myosotidium nobile and the gorgeous Embothrium coccineum.

An effective exhibit of alpines came from Mr. M. Pritchard, Christchurch, Hants, which was admirably arranged without overcrowding the various subjects. Aubrietias were arranged in masses, and included A. Dr. Mules, A. Wallacei, A. Lilac Queen, and Bridesmaid. Primulas were in fine form, especially the Sieboldi varieties, while P. japonica atro-sanguinea and P. capitata were also quite attractive. Other leading features were the saxifragas and Daphne cneorum.

Mr. C. Elliott, Six Hills Nurseries, Stevenage, again presented a rockery, arranged artistically. The chief features were Anemone pulsatilla in splendid condition; Morisia hypogæa, Viola gracilis, and a good variety of saxifragas and aubretias. Mr. R. Pritchard, West Moors, Wimborne, Dorset, staged a small but interesting display, particularly attractive were Campanula Stevensiana, Primula rosea, P. ciliata coccinea, Viola gracilis lutea, and a variety of saxifragas.

Messrs. Whitelegg and Page, The Nurseries, Chislehurst, occupied the end of a double table with a nice exhibit arranged with stone. The best features were Sedum obtusatum, aubrietias in variety, Primula Veitchi, P. J. H. Wilson, P. Forresti, and P. rosea; while saxifragas were employed at the edges of the mounds. The Wargrave Plant Farm, Lim., The Arcade, Liverpool Street, had an effective exhibit of rock plants arranged in a natural style, though the cocoanut fibre was perhaps a little too prominent. The most striking subjects employed were Aubretia Lloyd Edwards, A. Wallacei, and A. Leichtlini. The quaint Viola sulphureum was also in evidence, with Iris Susiana and Primula megasæfolia.

A fine display of rock plants came from Messrs. J. Piper and Sons, Barnes, Surrey, the whole arrangement being most natural and effective. The primulas were certainly a fine illustration of their varied types.

Messrs. Reamsbottom and Co., Geashill, Ireland, again had a display of St. Brigid anemones, which embraced a large range of colours; they just wanted a gleam of sunshine to produce a gorgeous piece of colouring. Mr. James Box, Lindfield, Haywards Heath, occupied a corner of the hall with hardy flowers. In the background were noted some fine Moutan pæonies, with Azalea mollis, while in the foreground, arranged naturally, were fine groups of Primula cashmeriana, P. malacoides, P. rosea, with saxifragas, Lithospermum prostratum and Morisia hypogæa, all in good form.

Messrs. G. Jackman and Son, Woking, had a bright exhibit of hardy flowers, with some excellent examples of forced shrubs at the back. There were ribes in variety, Spiræa arguta, and Mespilus canadensis; while other notable features were Iris cyanea, Incarvillea grandiflora, Thalictrum anemonoides, Muscaria Heavenly Blue, and M. botryoides alba. The whole exhibit was much admired. Messrs. Baker, Codsall, Wolverhampton, presented a bright display.

A bright and effective exhibit of hardy flowers came from Mr. H. Hemsley, Nurseries, Crawley, the whole being most tastefully arranged, the background being composed of spiræas, white broom, berberis, and acers. The aubrietias here were quite a feature, especially the varieties variegata argentea, A. aurea, and A. deltoides variegata, these, with Peter Barr, A. Lechtlini, making quite a feature; while Gentiana bavarica, G. verna, and the white form G. v. alba, attracted much attention, as did also Helichryfeature, especially the varieties A. variegata argentea, A. aurea, and A. deltoides variegata, these, with Peter Barr, A. Leichtlini, making quite a feature; while Gentiana bavarica, G. verna, and the white form, G. v. alba, attracted much attention; as did also Helichrysum bellitoides.

A group of fragrant lilacs from Messrs. Paul and Son, Cheshunt, showed the great variety of colour now obtainable in these fine flowering shrubs; Alphonse Lavallee, Mdme. Lemoine (double), Marie Legraye, Souv. de Leon Spathe, Doyenne Keteleer, and alba grandiflora were especially good, and carried very fine spikes. From Messrs. R. Gill and Sons, Falmouth, came a collection of cut rhododendrons, in which R. cornubia shone brilliantly, while others noteworthy were Duchess of Cornwall, R. barbatum, and a large number of seedlings. Primula Winteri was also in fine form, while Mysotidium nobile was just opening well.

Messrs. W. Cutbush and Son, Highgate, were represented by a miscellaneous group which made quite an attractive display, and a fine bank of carnations arranged lightly with ferns and palms.

Messrs. H. B. May and Sons, Upper Edmonton, staged a table of ferns and clematises. In the former were groups of Pteris Summersi, Todea africana, Adiantum micropinnulus, and osmundas in variety. The clematises included well-flowered plants of Nellie Moser, Lucie Lemoine, and Miss Bateman. Messrs. Wills and Segar, Onslow Crescent, South Kensington, staged a small exhibit of gerbera hybrids arranged in tall glass vases, while the centre was occupied with Calla Pentlandi; the groundwork of selaginella was relieved with dot plants of Nidularium fulgens.

Messrs. Jas. Veitch and Sons, Chelsea, staged a very bright lot of cyclamens, all well-flowered plants, carrying large blooms of white, purple, lilac, and crimson colouring. The same firm had a few Darwin tulips in bright colours. Messrs. H. Cannell and Sons, Swanley, disposed huge bunches of zonal pelargoniums in glass vases, and made up a very bright exhibit.

Messrs. Wm. Paul and Son, Waltham Cross, brought up dainty flowering plants of Rowena, Fairy, and Tausendschon, all beautiful climbing roses; their dwarf pot plants of Amy, Sylvia, Mrs. Chas. Hunter, the new white Tausendschon, and Juliet, with cut flowers of the lovely Sunburst and the yellow Banksian roses. Mr. George Prince, Longworth, had a charming group of cut roses, and made a special feature of Juliet, Mrs. W. J. Grant, A. R. Goodwin, Fortune's Yellow, and Richmond.

Messrs. Stuart Low and Co., Enfield, showed golden-flowered acacias, and fine heads of the newer hydrangeas—Mdme. Mouillere and Radiant; and a few perpetual carnations.

Auriculas from Mr. James Douglas, Great Bookham, were a good feature of the show, as the plants were well grown, and the varieties of the best, namely, Ruby, Old Rose, Roxburgh, Admiration, Mrs. Gardener, Harrison Weir, and Napoleon. Primula viscosa Jean Douglas (A.M.), with bright rose, white-eyed flowers, and P. v. Othello (A.M.), with smaller, dark purple flowers, were two fine new varieties exhibited by Mr. Douglas.

Messrs. Allwood Brothers, Haywards Heath, showed perpetual carnations well. Mr. H. Burnett's splendid carnations were much admired, and he set up grand vases of R. F. Felton, Calypso, Marmion, Mrs. C. F. Raphael, Sultan, Carola, and White Wonder.

Messrs. W. Wells and Co., Lim., Merstham, exhibited some well-grown carnations.

ORCHID COMMITTEE.

A very attractive and well-arranged group of orchids from Messrs. Sander and Sons, St. Albans, was well furnished with the fragrant Cattleya Schroderæ, the golden Oncidium concolor, the bright crimson Renanthera Imschootiana, many graceful odontoglossoms, and Cymbidium insigne. Messrs. Armstrong and Brown, Tunbridge Wells, brought up a nice lot of orchids, but the pots were rather too much in evidence. Brasso-cattleya Mdme. Hye, Zygopetalum Armstrongæ, the bright yellow Lælio-cattleya Myra, Dendrobium nobile virginale, and Odontioda Charlesworthi were a few of the best things.

Mr. Thurgood, gardener to H. T. Pitt, Esq., Stamford Hill, had a fairly large group of orchids; odontoglossums were freely shown, and there were cymbidiums, miltonias, cypripediums, the rare and quaint Chondrorhyncha Chestertoni, and the no less curious and umbellate Cirrhopetalum Mastersianum. Messrs. Hassall and Co., Southgate, showed the pretty Cattleya speciosissima Stanleyi, C. Mendeli, and a few odontoglossums.

Mr. W. Balmforth, gardener to F. Menteith Ogilvie, Esq., The Shrubbery, Oxford, had a splendid plant of Odontoglossum Ossulstoni Shrubbery var., with a branching spike of twenty-eight grand flowers. Messrs. Stuart Low and Co., Enfield, displayed masses of Dendrobium Wardianum, with Cattleya Schroderæ, L.-c. callistoglossa, L.-c. Bella, and the white form of Lycaste Skinneri.

Odontioda Cooksoniæ Ralli's var. (A.M.) was shown by Mr. Hunt, gardener to Pantia Ralli, Esq., Ashtead Park, Leatherhead; the white tip to the lip greatly enhanced the beauty of this crimson-scarlet orchid. Odontoglossum eximium Warnham Court var. (F.C.C.), shown by Mr. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham, was very finely formed, and marked with deep crimson-purple on a blush ground.

A very large and fine plant of Cymbidium Humbloti was exhibited by Messrs. Charlesworth and Co., Haywards Heath. This is a rare species from Madagascar, and it has long, deep green, strap-like leaves, and a big, branching spike of about 4ft. long, and about a score of green and blackish purple flowers on each of its six branches (F.C.C.). A group of odontoglossums and odontiodas from Mr. G. Day, gardener to H. S. Goodson, Esq., Fairlawn, Putney, attracted a good deal of attention. Of the odontiodas, Cassiope, Patricia, Bradshawæ, Charlesworthi, Bohnhofeæ, and Heatonense were the most notable, and their bright colouring was very effective.

An exceptionally well grown plant of Brasso-cattleya Heatonense Canary, carrying six very fine pale sulphur-yellow flowers, having pink and yellow shading in the big fringed lip (F.C.C.), was shown by Mr. H. Alexander, grower to Lieut.-Colonel Sir George Holford, Westonbirt, Gloucester. From the same collection came Cypripedinm Roundhead (F.C.C.). M. Firmin Lambeau, Brussels, exhibited Cattleya intertexta var. Juliette, a beautiful white form (A.M.). Lælio-cattleya Dominiana Southfield var., with a huge ruby-purple lip, gained a F.C.C. for W. Walters Butler, Esq., Southfields, Birmingham.

Messrs. J. and A. McBean contributed a fine plant of the rather rare Odontoglossum coronarium, carrying a dense spike of brown and yellow flowers; Cattleya Schroderæ, Miltonia Bleuiana McBean's var., and the gold and brown Odontoglossum trumposum, a cross between O. triumphans and O. cirrhosum, were other good things staged. Odontioda Keighleyensis ignita, very bright crimson-scarlet (A.M.), was also exhibited by the Messrs. McBean. Mr. S. W. Florey, Tracey's Nursery, Twickenham, showed Cattleya Schroderæ and Oncidium concolor in

(Continued on page 249.)

MICHAELMAS DAISIES.

Where space permits one cannot too strongly urge the importance of devoting a border to the cultivation of these charming autumn subjects, as by so doing, with a little attention to cultural details, one of the most glorious effects may be produced that it is possible to conceive. During the past few years many new and improved varieties have been introduced by various raisers, and the modern Michaelmas daisy is a distinct improvement upon the older race, being much more beautiful in habit and freer-flowering, therefore the importance of growing the newer and better varieties in preference to the old ones can hardly be over-estimated.

Whether these perennial asters are grown in a border entirely devoted to them, as the photograph depicts, or are included in the herbaceous border for an autumn display, they need a good depth of soil in which to root, and also the addition of a little well-decayed farmyard manure. We replant annually, but many suggest this is quite unnecessary; we find that if allowed to remain longer the clumps and resulting growths become too crowded, while vigour is secured by annually dividing and planting a portion of the outer growths, which develop into good specimens before flowering time.

Assuming that the plants have been lifted, carefully labelled, and laid in near by, and the ground prepared by digging or trenching, planting may be done without delay, when the ground is not saturated. Our border takes four rows of regularly-planted varieties, with back plants variously arranged with the shrubs, etc., and these include the vigorous-growing varieties of the Novi Belgi and Novæ Angliæ types. The four rows on the border proper contain nothing but varieties of the cordifolius and ericoides section. Four feet between each plant may seem a very liberal amount of space, but as growth advances it will be found that it is none too much, providing the plants are well staked out as they should be. Plant firmly, and rake the surface of the border neatly after labelling.

The ericoides varieties are quite easily increased, and invariably start away well, but the cordifolius forms make but few growths in comparison, and require rather more attention; therefore it will be well after planting to make quite sure against the attack of slugs by placing a good sprinkling of sharp cinder ashes around them. On very heavy soils a little old potting material placed round the roots will materially assist the young plants.

Staking is a very important item, and requires attention early. The modus operandi here is to insert four, five, or even six flower stakes as near to the base of the plant as permissible, but in an outward slanting direction, and equidistant, and train a good growth to each stick, thinning out the weaker shoots, and those not required. Unless a growth considerably outdistances the others, I do not advise stopping.

During hot weather a mulching is highly beneficial, and copious supplies of water, with damping overhead in the evening, will be found desirable, as will also a dusting of artificial manure before a shower. If the plants show signs of an attack from mildew syringe them with a good specific.

To enumerate the varieties would be a large undertaking, but perhaps a good dozen will suffice, with their approximate heights.

Climax is a grand variety of the Novi Belgi type, six feet high, blue: Mrs. F. W. Rayner, red, of Novæ Angliæ type, is not one of the best for cutting, but fine for its colour in the border, four feet: St. Egwin, a beautiful pink variety, is not too tall, and is fine for its colour: Perfection, white, 3½ft., is a grand variety: Hon. Edith Gibbs, pale blue, 4ft., is a standard variety; Paragon, rich blue, cordifolius section, is 3½ft. high; Cinderella belongs to the same section, and is white, 4ft.: Desire, an ericoide variety, is a good front-row plant, with white flowers; Ringdove, 4ft., is rosy-lavender; and Novelty, 3½ft., is blue; White Heather, dwarf, but very free, and Esther, a complanion plant, with rose flowers, are a fine pair. The above are twelve of various heights and colours and of the different sections, and do not include any varieties of Amellus, which are preferably grown elsewhere than in the Michaelmas daisy border.

EDWIN BECKETT, V.M.H.

A BORDER OF MICHAELMAS DAISIES AT ALDENHAM HOUSE, ELSTREE.

APRIL IN THE ROSE GARDEN.

In the ordinary course of events many of our roses will be putting forth growth freely by the middle or end of April. I have upon more than one occasion cut blooms from such early varieties as Rêve d'Or, Charles Lawson, and Coupe d'Hébé in very sheltered corners during a mild and early season in April.

In such sheltered spots we frequently find a colony of insect pests, chiefly greenfly, ready to spread widely as soon as the weather becomes suitable. Attack them while in a small compass; one cannot begin too soon nor be too persistent in keeping down the first arrivals.

Some forward varieties will have broken into new growth sufficiently to show where they are too crowded; remove the badly placed growths before they reduce the plant's energies. Shoots that threaten to overcrowd the centre of the plants must be cut or pinched out as soon as they can be handled.

Upon the early growths, especially among the forwardest Damasks, Bourbons, and a few of the hybrids, we may be troubled with an occasional caterpillar or rose grub. Examine any curled or eaten leaves, and pinch the grub between finger and thumb. We must be quick at this, for the majority of these little foes are wonderfully smart in dropping to the ground upon the slightest disturbance near them. They are very sensitive to a slight jar, and seem always ready to fall lightly, suspended by an almost invisible silken thread, by which they regain their position when all is quiet once more. Although the ordinary insecticides are undoubtedly distasteful and injurious to this foe, I would put my chief dependence in an early use of the finger and thumb treatment. If you kill the few first at once, I do not think there is nearly the same trouble with successive attacks as in the case of the aphides, which seem to appear in batches; so much so that not a few growers still remark that they come with the east winds, etc. When such conditions prevail, rose growth is partly at a standstill, and the insects increase so quickly that the whole of the youngest growth is smothered in a very short time. Here, again, one cannot possibly commence washing too soon. There are quite a number of cheap and reliable washes on the market now, and I will give a warning against any temptation to use these at a greater strength than advised by the manufacturer. If not successful at first, simply give a further wash. Indeed, one cannot kill both insects and eggs at one wash without having it too strong for safety to the young and tender growths. The majority of our successful growers commence early and keep up a more or less continuous spraying at a rather weaker strength all through the growing season, and this seldom fails to keep both insects and mildew away, besides securing clean and pleasing foliage at all times.

Now that pruning is completed, the light forking in of some good mulchings will be of great benefit as the roots will be in a more suitable condition to make use of the food. It does not matter much what class of manure is used, so long as it is well rotted and that of a lighter nature reserved for the stiffer soils, and heavier material where the soil is naturally light and quick in its drainage.

Upon the stems of some old plants, and especially in the case of standards we find a larger amount of moss lichen than usual, owing to the mild and wet winter, and the dripping summer and autumn of last year. A spray made up of a wineglassful of soluble paraffin to a gallon of warm water will kill this; or a little freshly slaked lime may be put upon the stems in white-wash form mixed with clear water. If neglected, this lichen soon chokes the base of standard heads and keeps the life-giving air and light from the growth.

Under glass we shall be securing the second crop of flowers from the earliest forced pot plants. I need say little more here than remind readers once more of the great necessity for early measures against insects and mildew.

Quite a number of own-root roses may be struck at this date. Use the three-parts ripened growths that can be cut away from below the flowers when partly pruning back after the blossom has been cut or has passed its beauty. Lengths of three eyes, or some side pieces that did not flower, may be taken off with a small heel of the older wood.

Inserted in coarse sand, kept close in a temperature of 65 degrees for three or four weeks, and not allowed to be dry at any time, a large percentage of the cuttings will callus. As soon as they have roots three-quarters of an inch in length, lift them very carefully, and insert in small pots in a mixture of leaf-soil, good loam, and sharp sand in equal proportions. Keep them close for a while, and repot, using richer compost, growing them on in the usual manner. A stock of many varieties that do not produce a sufficient quantity of buds for summer propagation outdoors may be worked up in this way; planting out the rooted cuttings from the tiny pots instead of potting them.

Rosarian.

Eucalyptus citriodora. — This species of eucalyptus is readily distinguished from all the other gum trees, by reason of the delicious citron-like fragrance of its young foliage. Like the other members of the genus, the juvenile leaves are very distinct from the mature ones, being of a rough, hairy nature; while the others are quite smooth. It is the rough leaves that are scented, the mature ones needing to be crushed before any fragrance is manifest.—T.

Protecting Fruit Buds.—Look out for bullfinches and other pests likely to damage buds of fruit trees. Sparrows, mice, and rats are frequently very destructive to pear and apple trees growing on walls, and should be checked by the best means available. Traps may be set nightly for mice and rats, but when these fail a little vermin-killer should be made use of. Hang nets in front of the trees to keep away sparrows and bullfinches, or syringe well with quassia extract, or some other distasteful insecticide. We find the bullfinch most destructive to plums, and, in some seasons have found it most difficult to prevent injury. All our bush apple trees usually have a good syringing (just before the buds open) with lime and soot water, about the thickness of new milk, and we find it very useful as a preventive.—H. Markham, Wrotham Park Gardens.

FERTILISERS FOR FRUIT CROPS.

For many years I have employed lime, phosphates and potash, in the form of either kainit or sulphate of potash, in the cultivation of fruits, both outdoors and indoors, with exceptional success. When dealing with pears, plums, and apples out of doors I have sometimes had to root-prune trees that were making rampant growth, before supplying the fertilisers named, in order to check exuberance in the branches and to foster the production of fibrous roots, which are so essential to fruit trees of all kinds.

With judicious feeding and the preservation of all the fibrous roots within a depth of about nine inches, much may be done to induce free fruiting in trees that have been badly managed for some years, as evidenced by some old stagers that came under my notice a few days ago. But this method of once more securing a balance between root and branch, which had been upset by excessive pruning and the destruction of the roots that absorb the fruit-producing food, is longer in producing the desired object than is the case when root-pruning is resorted to. Besides, if a wide trench is taken out when the trees are root-pruned facilities are afforded for enriching the soil with phosphates, an advantage of considerable value, as phosphates are not very soluble, and consequently, do not readily permeate the medium. The potash and lime are best applied to the surface, as they will find their way downwards, and will work up and down by capillarity and rain as long as they remain in the soil. Even for newly-planted trees only the phosphates should be mixed with the soil.

In a small experimental garden discovered the other day, I found espalier-trained apples and pears a mass of fruit buds, and showing little indication of wood growth. These trees are growing in a soil naturally very rich in potash, but almost entirely deficient in phosphates and lime. When the trees were planted a very liberal dressing of basic slag was worked into the soil, and lime and kainit have been applied to the surface every year since. No digging is ever done within a certain radius of the stem, and more fruitful trees it would be hard to find, but as they extend so little annually it is intended to encourage more branch growth this summer by heavily mulching with farmyard manure.

I do not wish to convey the idea that the trees are in a starved condition, as that is not the case, for the heavy crops of fine fruit they carry is evidence to the contrary. I wish more particularly to point out the fruiting effect produced on trees by a high percentage of phosphates, lime, and potash in soils, if the fibrous roots are preserved near the surface of the soil.

I may, however, add that the trees of pears and apples referred to are grown on dwarfing stocks, and as their dwarfing influence is due to a preponderance of fibrous roots, the tendency of the trees to produce fruit in abundance is only what would be expected of them. But similar trees almost adjoining, and growing in the ordinary soil, without the addition of any of the food constituents mentioned, only produce a few blooms, and some of these weaklings, with the result that strong growth in the twigs takes the place of the fine crops of fruit in the other trees, and therefore settles beyond dispute, so far as this particular soil is concerned, that phosphates, potash, and lime are the auxiliary plant foods to employ in fruit growing. Hibernia.

DWARF ANNUALS FOR THE ROCKERY.

Although the keen alpine grower evinces a desire to depend entirely or almost wholly on perennials for his rockery, it is folly to neglect the many dwarf annuals which are obtainable, and are of very high value for the rock garden or small rockery. New rockeries are, as a rule, exceedingly bare until the alpines have had time to spread, and they can be greatly beautified with the assistance of a few packets of annual flower seeds and at a trifling expense. There are also many rockeries in which bulbous plants are cultivated. The departure of the leaves of these often causes bare and unsightly spots, which are all the better for being clothed with pretty flowers. In many ways, indeed, these dwarf annuals can be employed, and some of them are of exquisite beauty, and only the pedant can find fault with their presence in the finest and most choice collections of alpine flowers.

In the following notes an endeavour is made to point out a few of the best annuals for the rockery. There is no need to give elaborate cultural details. The hardy annuals can be sown where they are to bloom in chinks in the rockwork or on the level spots and just covered with some fine soil. The half-hardy ones—not so good in some ways, but often very beautiful, are treated as other half-hardy annuals, being either sown later in the open, or under glass in March, and planted out where they are to bloom in May or early June. To begin with, we have Abronia umbellata, a trailer with rosy-purple flowers of verbena-like form. This is half-hardy, and is good for sunny places in sandy soil. Æthionema Buxbaumi is an annual Lebanon candytuft of much beauty, with pretty rosy flowers on plants about three inches high. It is a hardy annual, and likes sun and lime. We have also seen the half-hardy annual ageratum, so much used for bedding, employed successfully on rockeries. The dwarfer varieties, such as Mexicanum capella and Little Blue Star, are excellent, and are respectively rose-chamois and pale blue. Alyssums Little Dorrit or nanum, and Thorburn's Bouquet, are charming white mats or carpetworts, classed with hardy annuals.

For sunny places the pimpernels are pretty. Anagallis indica, deep blue and a trailer, is hardy. The varieties of A. Monelli can be had in various colours, and are half-hardy annuals. Arctotis breviscapa is a showy orange-flowered half hardy annual for sunny places. Campanula attica, violet-purple or white, six inches high, is a pretty gem, and is a hardy annual. In Clintonia pulchella we find one of our most charming half-hardy flowers of this class, its flowers of blue, white, and yellow being very delightful. We have also observed some of the dwarfer forms of the Indian pink (Dianthus sinensis Heddewigi) used with advantage, and these are so well known as hardy annuals that no further notice is called for. Eucharidium Breweri is a good nine-inch hardy annual with pleasing flowers of lilac-purple and white. The succulent-leaved Grammanthes gentianoides, of shaded orange-red, is fine for sandy soil in sun, and is a half-hardy annual plant. The rose-coloured Gypsophila muralis is a good hardy subject for our rockeries, especially on chalky rockeries. Gilia or Fenzlia dianthoides is a pretty six-inch rosy-purple species. For big rockeries we have seen the Glauciums or Horned Poppies employed, but they are too coarse for any but rough rockeries. They are perennials, but may be treated as annuals.

There is no more lovely flower than the violet cress (Ionopsidium acaule) only an inch or two high, and white, tinged with violet. It is a charming thing for moist places in sun or shade, and is a hardy annual. Not many now grow the Kaulfussias, nice little hardy composites, with purple or dark-red flowers, and fairly good for our purpose, being only about six inches high. They like sun.

The Leptosiphons deserve a word of praise, either for the rockery or border; they are lovely things some six inches high, and give shades of orange, red, yellow, white, etc. It is needless to do more than mention Limnanthes Douglasi; and the same may be said of the Virginian stock, Malcolmia maritima, Medicage echinus, the Calvary Clover, is grown for its curious, twisted seed vessels, and not for its effect. Among the mesembryanthemums or noon flowers, we have the trailing, yellow M. glabrum, and M. tricolor, a lovely annual of half-hardy habit, with the ice plant, M. crystallinum. Give these sun. The Love-in-a-mist (Nigella damascena) is a well-known hardy annual, which looks well on a rockery where there is plenty of room; and the rosy-purple Oxalis rosea is best treated as a half-hardy subject for a sunny rockery. The beautiful hardy annual called Phacelia campanularia is a charming, deep-blue subject about nine inches high. The dwarf varieties of the popular Phlox Drummondi are all excellent. An uncommon hardy annual is Polygonum capitatum, 3in. high, with grey leaves and pink flower heads. Portulacas, if properly managed, are very fine with their varied colours. Sow these where they are to flower towards the end of April, and thin out well.

Sabbatia campestris, rose, with a yellow star in the centre, is a good half-hardy plant. Sanvitalia procumbens, yellow, with black eye; and the well-known Saponaria ocymoides, are fine, and can be sown where they are to bloom in April. Sedum cæruleum, of lovely pale blue, is a gem, and an excellent half-hardy species for sowing where it is to flower. Saxifraga cymbalaria is a capital little yellow-flowered Saxifrage of hardy character. Silene pendula compacta requires no description, and is most useful for our purpose. Venus's Looking Glass (Specularia speculum), white; Sphenogyne speciosa, buff and black; dwarf Tropæolums of the Tom Thumb class; and Veronica glauca, blue, may also be mentioned as useful subjects for rockeries. Dwarf antirrhinums, treated as annuals, are most useful.

With the aid of a selection of the above our rockeries may be rendered bright at their dullest season—late summer and autumn. S. ARNOTT.

French Beans.—To maintain the supply make liberal sowings in pits or frames in rich soil. Where the pits are not available for immediate sowing, the required number of plants may be raised in advance by sowing three seeds in 60-sized pots, and planting out as the pits become available. Plants in pots which are swelling up the pods should be treated liberally; maintain a brisk heat with plenty of atmospheric moisture, and use the syringe freely to prevent the attacks of red-spider.—W. MESSENGER.

Lobelia tenuior.—The large size of the individual blooms are a marked characteristic of this lobelia, which, for greenhouse decoration during the summer, is exceedingly valuable. It has a somewhat loose habit, and grown in pots it needs support. This habit fits it for growing in a suspended basket, and in this way it is much admired. The normal form has flowers of a rich cobalt blue tint, but there is also a form with rosy blossoms. It is, however, at least, to my mind, less pleasing that the older form.—K.

THE ALPINE HOUSE AT KEW.

This little structure is, as might be expected, very bright with a choice collection of flowering plants, which are delightfully fresh and bright, while their brethren out of doors have had to run the gauntlet of some very heavy storms.

Of bulbous plants the following are particularly noticeable: Narcissus albicans, bulbocodium, bulbocodium citrinus, cyclamineus, triandrus, and Queen of Spain. The large, brilliantly-coloured flowers of Tulipa Forsteriana, a native of Bokhara, stand out like giants among most of their associates, while other species are the pretty little Tulipa pulchella, T. Kaufmanniana, and T. præstans.

The rich blue flowers of Scilla sibirica are admired by everyone; while the more lavender tint of Scilla italica præcox is also very pretty. Chionodoxas are really charming. In addition to the ordinary forms, the pure white variety of C. Luciliæ attracts by reason of its beauty and rarity. The different Grape Hyacinths are so well suited for pot culture that it is surprising they are not more often grown in this way, the kinds represented being Muscari botryoides, M. Heldreichi, and the garden form known as Heavenly Blue. The Asiatic Puschkinia scilloides is flowering freely, as also are Corydalis bulbosa Halleri, Erythronium giganteum, and Trillium nivale. Anemones include the Scarlet Windflower (A. fulgens), the sky-blue A. apennina, and the deeper-tinted A. blanda atro-cærulea.

Finely-developed specimens of the new Primula Winteri show well what a charming plant this is; while other kinds are P. muscosa hybrida, a pretty ruby-coloured flower with a yellow eye, the well-known P. denticulata, and the charming little P. hirsuta, with violet-rose blossoms.

Numerous mossy and other saxifrages include Saxifraga ambigua, white; S. apiculata, yellow; and its white variety; S. Burseriana, white; S. Boydi, pale yellow; S. Faldonside, pale yellow, which was given an Award of Merit at Westminster on March 4; the very distinct S. Griesbachi; S. marginata, white; S. Rocheliana, white; and S. scardica, white.

Other flowers that contribute to this charming display are the golden-flowered Morisea hypogæa; the little North American May Flower, Epigæa repens; Shortia galacifolia; and the rich purple-coloured Viola gracilis, which has within the last two or three years come so prominently forward. K.

PEACHES AS CORDONS.

I was much interested in reading your reference to Mr. G. Mullens (page 56, "G.M." of January 25), and his system of training peach trees as cordons. I can quite understand how fine the fruits were so grown, as I am a firm believer in the training of fruit trees as cordons in gardens—but not, of course, to the exclusion of all other forms. From time to time I used to visit a certain garden, and in one house two branches of a peach tree growing in a confined space were trained along two horizontal wires, 18in. apart, and many feet in length. On these branches large spurs were formed, and they were treated as cordons. Much finer fruits were borne annually on these branches than on the remaining portion of the tree trained as a fan. In small houses there is not room for many large trees, but a number of cordons may be grown. GEO. GARNER.

BROAD AND LONGPOD BEANS.

Broad and Longpod beans are not cultivated in cottage gardens and allotments to the extent they were in days gone by. Probably, they were grown so largely in the old days because pig-keeping was then synonymous, as it were, with the possession of the smallest strip of garden soil. Bacon and beans formed a dish that, according to some accounts, added a new word to the English distionary. That word was "beanfeast," and present-day revellers who depart for a "beano" in the country may note the absence of the bacon and beans that at one time was the inseparable accompaniment of such a joyous occasion. Cottagers and allotment-holders do not keep pigs now, at least only in a very few cases, for the Local Government Board has imposed all sorts of restrictions, with which it is generally impossible for them to comply. Whether this accounts for the decline in broad bean culture or not is, of course, a mere matter of speculation. At any rate, where at one time a double crop of beans and potatoes was the rule, it is now rather the exception.

Curious, indeed, are the historical references to beans in ages past. In the matter of colour they appeared to have played quite an important part, even unto the apportionment of life and death. White and black beans have been used for the purpose of casting lots to decide whom of several condemned persons should be executed. The black bean meant death, and invariably it was the case that this variety carried a sinister meaning of some kind or another with it. Some say that the modern practice of "blackballing" is a relic of the old Grecian custom of electing political representatives by the casting of white and black beans into a helmet.

It was an old custom, in the middle ages, to place a bean and a pea in the cake prepared for the "twelfth night" festivities. The person who discovered the bean was at once elected King, and she who found the pea was honoured as Queen. Many other curious customs of a similar nature were observed at one time and another.

As a vegetable, the earliest variety of bean to be grown in this country was the Mazagan. It originated in a Portuguese settlement on the coast of Africa, and was typified by rather small and narrow pods, containing four or five small seeds. In the December (1846) issue of the "Horticultural Magazine," the best varieties then in cultivation were described as follows: Early Mazagan, Green Long Pod, Dutch Long Pod, Windsor (or Mumford), Green Windsor (or Toker), Long Pod, Dwarf Fan, Red Blossomed, White Blossomed, Violette, Dark Red, and Fullard's Golden-podded bean—the latter being described as a very handsome field bean. The Long Pods were originally derived from the Mazagan, and from the Spanish Long Pod came the Broad Windsor. The latter took its name from the town of Windsor, where the fugitive Dutch gardeners, who came over after the revolution, first grew them. Green Longpods were first known as Green Genoa, and it is said that they were originally introduced from Italy. Many fine selections of Longpods, and also Improved Windsor Beans have been introduced of late, both for market and exhibition purposes.

The greatest amount of attention, however, seems to have been devoted to runner beans of late years. A generation ago, or even less, there were only three types of runner bean in use, viz., the Common Scarlet, the White, and the Painted Lady. Champion Scarlet appeared in 1871, and this heralded the first improvement in size of pod, as compared with the ordinary common or garden variety of runner bean. Ne Plus Ultra then entered the lists, and has been grown extensively from that day to this.

At the present time, the number of different varieties of runner beans are legion. Hackwood Park Success is a fine cropping bean raised by Mr. Bowerman, formerly head gardener at that place. For exhibition purposes, two of the best known sorts are Scarlet Emperor and Best of All, while another large and prolific runner bean for general purposes is Prizewinner.

The best method of securing a good crop of runner beans is to grow them in trenches after the style of celery. They have a very extensive rooting habit, and so the rooting medium must of necessity be well supplied with manure and moisture to help in the development of the large leaf growth that these plants carry. After digging out a trench, a layer of good farmyard manure should be placed in the bottom, and well consolidated. On the top of this should be placed a few inches of good soil. The staking of runner beans is very important, for when liberal treatment is meted out to them they often run up to a great height. Also, to secure the best results, the trenches should be placed 8ft. or 10ft. apart, so that the plants may have access to as much air and sunlight as possible. They are of a very tender habit; hence, open-air sowings should not be commenced until May is well in.

A variety of bean that is exceedingly popular on the Continent, but seldom encountered in this country, is the Waxpod or Butter Bean. Of this type of bean there are both dwarf and climbing varieties. The Golden Waxpod is a dwarf kind and a prolific cropper, which ought to be grown in every kitchen garden. Another fine dwarf butter bean is the Centenary Golden-Podded, which is earlier than the older Golden Scimitar. From America comes the Golden-Eyed Wax Butter Bean, which is of dwarf habit and early and free-bearing. One of the best varieties of the Golden Scimitar type is Henderson Wax, which yields a round, fleshy, and remarkably solid pod. Butter beans should be cooked whole, for if the pods are in a young state they are extremely fleshy and tender, and most of them are free from any objectionable stringiness.

J. C. Newsham.

Magnolia Campbelli.—This Himalayan species of magnolia would appear to appreciate the mild winter we have had, for fine blooms of it have been shown two or three times at the Royal Horticultural Hall. It first flowered in this country about thirty years ago, which circumstance aroused much interest.—W. T.

Cocos flexuosa. — While many palms are appreciated for their beauty in a small state, the reverse holds good with regard to this, for, when young, the simple leaves, sparingly produced, are not at all striking. As they become large and much divided, they are justly valued for various decorative purposes, particularly for forming the background to groups of flowering plants.—K.

OFFICIAL GUIDE FOR KEW GARDENS.

An Official Guide has been appointed by the President of the Board of Agriculture and Fisheries to conduct parties of visitors round the collections contained in the gardens, plant houses, and museums, and to point out objects of particular botanical interest.

Two tours will be made daily, Sundays, Good Friday, Christmas Day, and Bank Holidays excepted, one of about an hour and a-half, starting at 11.30 each morning throughout the year, and one of about an hour at 3 each afternoon except during the months of June, July, and August, when the afternoon tour will start at 5 p.m.

In the mornings the plant houses and museums will be visited, and the parties will be limited to six persons. The afternoon parties, which will be limited to twenty persons, will be conducted round various portions of the outdoor collections. Should any afternoon prove wet, the museums, North gallery, and temperate house may be substituted.

A constable will be in attendance with each party to collect fees, and to prevent any unauthorised persons attaching themselves to the party.

The following scale of charges has been authorised: 2s. 6d. for each person attending a morning tour, and 1s. for each person attending an afternoon tour. The constable attached to the parties will collect the fees of visitors, who will sign their names in the book and pay their fees before the tour commences. Children under the age of twelve years cannot be included in the parties.

Visitors who wish to avail themselves of the services of the guide should attend at the Stone Portico of Cambridge Cottage, on the south side of Kew Green, near the church, shortly before the time at which the guide is advertised to start his tour. Anyone or any parties making application beforehand to the Director in writing to be included in a tour on a particular day, would have priority in the event of the authorised number of visitors for a party being exceeded.

WEEKLY PROGRAMME.

Monday.—Morning: Timbers of the World—Oak, Deal, Walnut, Teak, Mahogany, etc.: Wood Museums. Afternoon: Coniferous trees and their economic importance: southern portion of Arboretum.

Tuesday.—Morning: Palms, Bamboos, etc., and their economic uses; Palm House and Museum II. Afternoon: Herbaceous plants of Temperate countries, the principles of their classification, and their uses.

Wednesday.—Morning: Ferns and Fern Allies; Fern Houses and Museum II. Afternoon: General tour among trees and flowering shrubs.

Thursday.—Morning: Rubber, Fibres, Food Plants, Drugs, etc.; Economic Houses and Museum I. Afternoon: The Royal Botanic Gardens and their History; Famous trees, buildings, and other landmarks; Maps and Plans.

Friday.—Morning: Exotic plants of botanical or horticultural interest—Orchids, Cape plants, Begonias, Pitcher plants, etc.; T Range. Afternoon, Alpine and Water plants; Rock Garden and Aquatic Garden.

Saturday.—Morning: Flora of Warmer Temperate Regions—Australia, New Zealand, Himalaya, etc.; Temperate House and North Gallery. Afternoon: General tour.

Clematis indivisa.—Many of the hardy forms of clematis are forced into bloom for greenhouse decoration during the spring months, but in this species we have one that flowers naturally at this season. It is a native of New Zealand, and requires the protection of a greenhouse in this country; indeed, it is one of the best climbers we have for that structure. The blossoms are white and star-like.—T.

NEW PLANTS AND FLOWERS.

NARCISSUS JUDITH.

A very fine giant Leedsi variety with wide perianth segments and a pale sulphur yellow cup edged with yellow, and beautifully frilled. A.M., R.H.S., March 22. Mr. A. M. Wilson, Shovell, Bridgwater.

BRASSO-CATTLEYA CLIFTONI MAGNIFICUM.

A very fine orchid, and a distinct advance upon the original hybrid. The soft, rosy-lilac sepals and petals are very broad, and the large, fringed lip is rosy-purple. The parents of this beautiful variety are B.-c. Digbyana-Mossiæ and C. Trianæ Uplands var. F.C.C., R.H.S., March 22. F. Menteith Ogilvie, Esq. (gardener, Mr. Balmforth), The Shrubbery, Oxford.

CATTLEYA MAGNET.

A free-flowering hybrid derived from C. Mossiæ and C. Whitei. It has attractive, deep rich rose-purple flowers, with crimson-veined lip. A.M., R.H.S., March 22. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

CATTLEYA TITYUS, SHRUBBERY VAR.

Another very beautiful flower, with broad petals that, like the sepals, are blush-white, and have prettily frilled margins. The large lip is deep crimson-purple with golden blotches. This fine variety was obtained by crossing C. Enid with C. Octave Doin. A.M., R.H.S., March 22. F. Menteith Ogilvie, Esq., Oxford.

CATTLEYA TRIANÆ COLOSSAL.

An unusually large form with very broad sepals, which, like the petals, are soft purplish mauve. The lip is broad and frilled, rich deep crimson-purple, with orange-yellow throat. A.M., R.H.S., March 4. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester.

CATTLEYA TRIANÆ SOUV. DE LOUIS VERDOUCK.

This is a shapely white variety, of fine size and substance. A.M., R.H.S., March 22. Mons. Jules Hye de Crom, Ghent.

DENDROBIUM BIGIBBUM LADY COLMAN.

This is a beautiful variety of a fine old species, the dainty flowers being of a pale blush colour, almost white. A.M., R.H.S., March 4. Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate.

MILTONIODA HARWOODI, MOSS'S VAR.

A beautiful little orchid with Miltonia-shaped flowers of a salmon-rose colour. A charming hybrid between Miltonia vexillaria and Cochlioda Noezliana. A.M., R.H.S., March 4. J. S. Moss, Esq. (gardener, Mr. Kench), Wintershill, Bishop's Waltham.

ODONTIODA MOSSIÆ.

A distinct and pretty hybrid between Odontoglossum maculatum and Cochlioda Noezliana. It has reddish flowers with somewhat paler lobed lip. A.M., R.H.S., March 4. J. S. Moss, Esq.

ODONTOGLOSSUM CRISPUM COBB'S VAR.

A showy variety, bearing a large spike of fine and shapely flowers. The ground colour is white, and there is a large brown blotch on each sepal. A.M., R.H.S., March 22. Walter Cobb, Esq. (gardener, Mr. C. J. Salter), Rusper, Horsham.

ODONTOGLOSSUM EXIMIUM ALPHA.

A very handsome form of a now popular hybrid. It has large flowers of good shape, and these are heavily blotched and spotted with rich red-brown on a rosy-blush ground. F.C.C., R.H.S., March 4. Messrs. J. and A. McBean, Cooksbridge.

ONCIDIODA COOKSONIÆ, RALLI'S VARIETY.

An improved form of the hybrid between Oncidium macranthum and Cochlioda Noezliana. The flowers are of a rich, deep red colour, with a yellow apex to the lip. A.M., R.H.S., March 4. Pantia Ralli, Esq. (gardener, Mr. Hunt), Ashstead Park, Leatherhead.

OMPHALODES CAPPADOCICA.

A somewhat rare species in cultivation by no means new. It is a low-growing, hardy plant, bearing lax cymes of bright blue, white-eyed flowers, each bloom about half an inch across. A.M., R.H.S., March 22. Mr. Maurice Prichard, Christchurch.

MAZUS RUGOSUS.

A quaint little plant, and, in general appearance, somewhat between a small-growing but large-flowered lobelia, and a tiny mimulus. It is about an inch high, and has small tufted growths composed of little spathulate, serrately margined leaves. It increases by means of runners. The flowers are large for the size of the plant, an inch long, the lower lip being the prominent portion; this is rosy purple or light mauve, with two raised white crests, each spotted with yellowish-brown, and running from the base to the point the three apical lobes join. (See illustration, p. 165.) A.M., R.H.S., March 4. Wargrave Hardy Plant Farm, Lim., The Arcade, Liverpool Street, E.C.

PRIMULA PURDOMI.

An interesting and attractive new species illustrated in our issue of March 22. It was discovered by Mr. Purdom, in West Kar-Su, China, at an altitude of 10,000 to 11,000 feet, therefore it is expected to prove hardy. The leaves are from three to six inches long, tapering at both ends, and about half an inch broad at the middle. These, with the spikes and calyces, are mealy. The flowers are borne at the apex of a six-inch spike, in an umbel, and they are of a rosy-lilac or rosy-mauve shade, with pale greenish yellow eye. F.C.C., R.H.S., March 18. Messrs. Jas. Veitch and Sons, Chelsea.

DAFFODIL NARCISSUS JUDITH.

SAXIFRAGA FALDONSIDE.

This beautiful yellow saxifraga is a hybrid raised by Mr. Boyd, and it is far finer than S. Boydi. Among yellow, low-growing kinds it is what S. Burseriana gloria is among white ones. The blooms are quite large, and of a soft yellow shade, with deeper coloured base. It is very free, and carries its flowers on short stems. A first-rate plant for the rock garden. A.M., R.H.S., March 4. Sir Everard Hambro (gardener, Mr. Grandfield), Hayes, Kent.

SUB-TROPICAL PLANTS FOR WARM GARDENS.

Cordylines.

Cordyline australis, better known as Dracæna australis, is an extremely handsome object in the early summer, when bearing its great white flower panicles. It is a very common plant in Devon and Cornwall, and in every town fine plants are to be seen on every side. In Torquay alone there must be some thousands, for in the public gardens there are nearly two hundred splendid specimens, and they are also to be found in almost every private garden. One fine example in the public gardens, twelve feet in height, carried no fewer than seventeen huge flower heads, a number almost unprecedented on a single plant. The cordylines present a very beautiful sight when in full flower, the great branching bloom-sprays, three feet or more in length, crowded with white blossoms, resembling giant plumes. They are very sweetly scented, and are all day long haunted by insects innumerable.

In the type the leaves are narrow, but the seedlings, which are raised in great numbers in the south-west, vary considerably in their foliage, the leaves of some being fully three inches in breadth, these wide-leaved forms being far handsomer than the type. Cordyline australis is considered perfectly hardy in Devon and Cornwall. Exceptionally severe frosts, followed by a sunny day, sometimes kill the heads of the plants, but generally a number of suckers are, later on, thrown up from the base.

The finest specimen of Cordyline australis in the south-west is probably that at Enys. It is twenty feet in height, with a trunk circumference of six feet at one foot from the ground. A short distance above the ground level it divides into four main branches, which are sub-divided into about thirty heads, about ten of which usually flower annually. It is fifty years of age, and was raised from seed sent from Australia.

C. indivisa is very distinct from C. australis, though often confounded with it, and illustrations of C. australis have repeatedly appeared above the title of C. indivisa, while in many gardens C. australis is still grown under the latter name. C. indivisa is a native of New Zealand, where it grows at a considerable altitude. The leaves are very handsome, being about five feet in length, and five inches in breadth, blue-grey in colour, with a midrib of bright red. It first flowered in the Tresco Abbey gardens, Isles of Scilly, in 1895, and bloomed at Enys three years ago. The flower shoot is pendent, and is composed of countless minute blossoms, the spike yellow and blue-black in colour, being more curious than beautiful. It is a rare plant, but there are a dozen or more specimens in Cornwall.

C. Banksi is also a native of New Zealand, and is easily distinguished from either of the above-named species. It is of moderate growth, and rarely attains a greater height than six feet, and is generally clothed to the ground level with arching leaves four inches in breadth. The branchlets of its flower spikes are far fewer than those of C. australis, so that the white-blossomed panicles are lighter in appearance. Cordyline Banksi erythroracis is a variety with bright red midribs to the leaves.

Agaves.

The aloes, or agaves, succeed well in the south-west. In 1892 a splendid plant flowered at Kingswear. It was twenty-five feet in height, and bore over thirty flower clusters. In the torrid climes, the home of the aloe, its colour seems to merge into that of the stone and sand of its surroundings, and strikes no note of contrast to the prevailing monotony of the sun-scorched landscape, but where, as in this country, the strong curves of the massive leaves are thrown into high relief by infinite gradations of tender green, ranging in colour from the sombre tint of the yew to the soft hues of some of the Japanese maples, it forms a pleasing and effective incident in the colour scheme. The bloom stem is produced at the expense of the plant—since flowering is the "swan song" of the agave, as it is of the bamboo, the plant invariably dying after it has bloomed—and it is a matter of regret, rather than exultation, to view the throwing-up of the candelabrum-like flower spike that denotes the loss of a plant, which has for many years proved a noble feature in the garden.

The finest specimen of Agave americana known to the writer, which died a few

A LARGE GROUP OF CORDYLINE AUSTRALIS IN THE GARDENS AT ROZELLE, TORQUAY.

years ago without having flowered, had a circumference of forty-one feet; height of top of tallest leaf from the ground, eleven feet; length of longest leaf, eight feet seven inches; breadth of leaf, nineteen inches.

Melianthus and Semele.

Melianthus major is a South African plant, introduced into this country in 1688. It is striking by reason of the bright, strong, grey-green colour, which, at full maturity, covers the whole plant. The large feathery and indented leaves look very handsome in their verdant hue, and fit it for isolated positions on lawns, as well as for mixed planting, in which it is seen to the best advantage. It needs full sun, rich soil, plenty of water, and manure. In the autumn its magnificent leaves assume their graceful bend in the midrib, and the plant is even more beautiful than in the summer, showing, as it does, from every point, portions of the upper and under-surfaces of its lovely foliage. It has the reputation of being tender, but 12 degrees of frost has not harmed it. Not only does it show to advantage on rising ground, but such a situation, when exposed to the full sunshine, suits it, and from the greater dryness about the roots in winter it is able to withstand a few degrees of frost. It is an extremely handsome sub-tropical plant, and flowers regularly in the south-west.

Semele (Ruscus) androgyna is a very handsome climber. It is a native of the Canary Isles and Madeira, and in the latter island is said to add much to the charm of the landscape, and to be especially beautiful when wreathing the stonework at the entrance to quintas. The leaves, or cladodes, are about two feet in length, and are furnished with from twelve to twenty pinnate sections, which are of a brightly-polished green colour. As the foliage droops slightly the shining green of the great leaves is well displayed. The texture of the foliage is very leathery, and it is not uncommon for individual leaves to remain in a perfectly fresh condition for six or seven years. When well-established strong, asparagus-like shoots are thrown up that in vigorous specimens often attain a length of forty feet in one season.

In the summer small, greenish-white flowers, each about one-eighth of an inch across, are borne in clusters at the edges of the leaflets. Every cladode upon the plant is covered with these tiny blossoms, and the effect produced is pleasing, though it is owing to its attractiveness as a foliage, rather than a flowering, plant, that Semele androgyna is chiefly valuable. The flowers are followed by scarlet berries, and these are to be seen on plants grown in the open in Devon and Cornwall. It is an excellent subject for draping a wall or for rambling over a high fence, and is one of the handsomest of foliage plants.

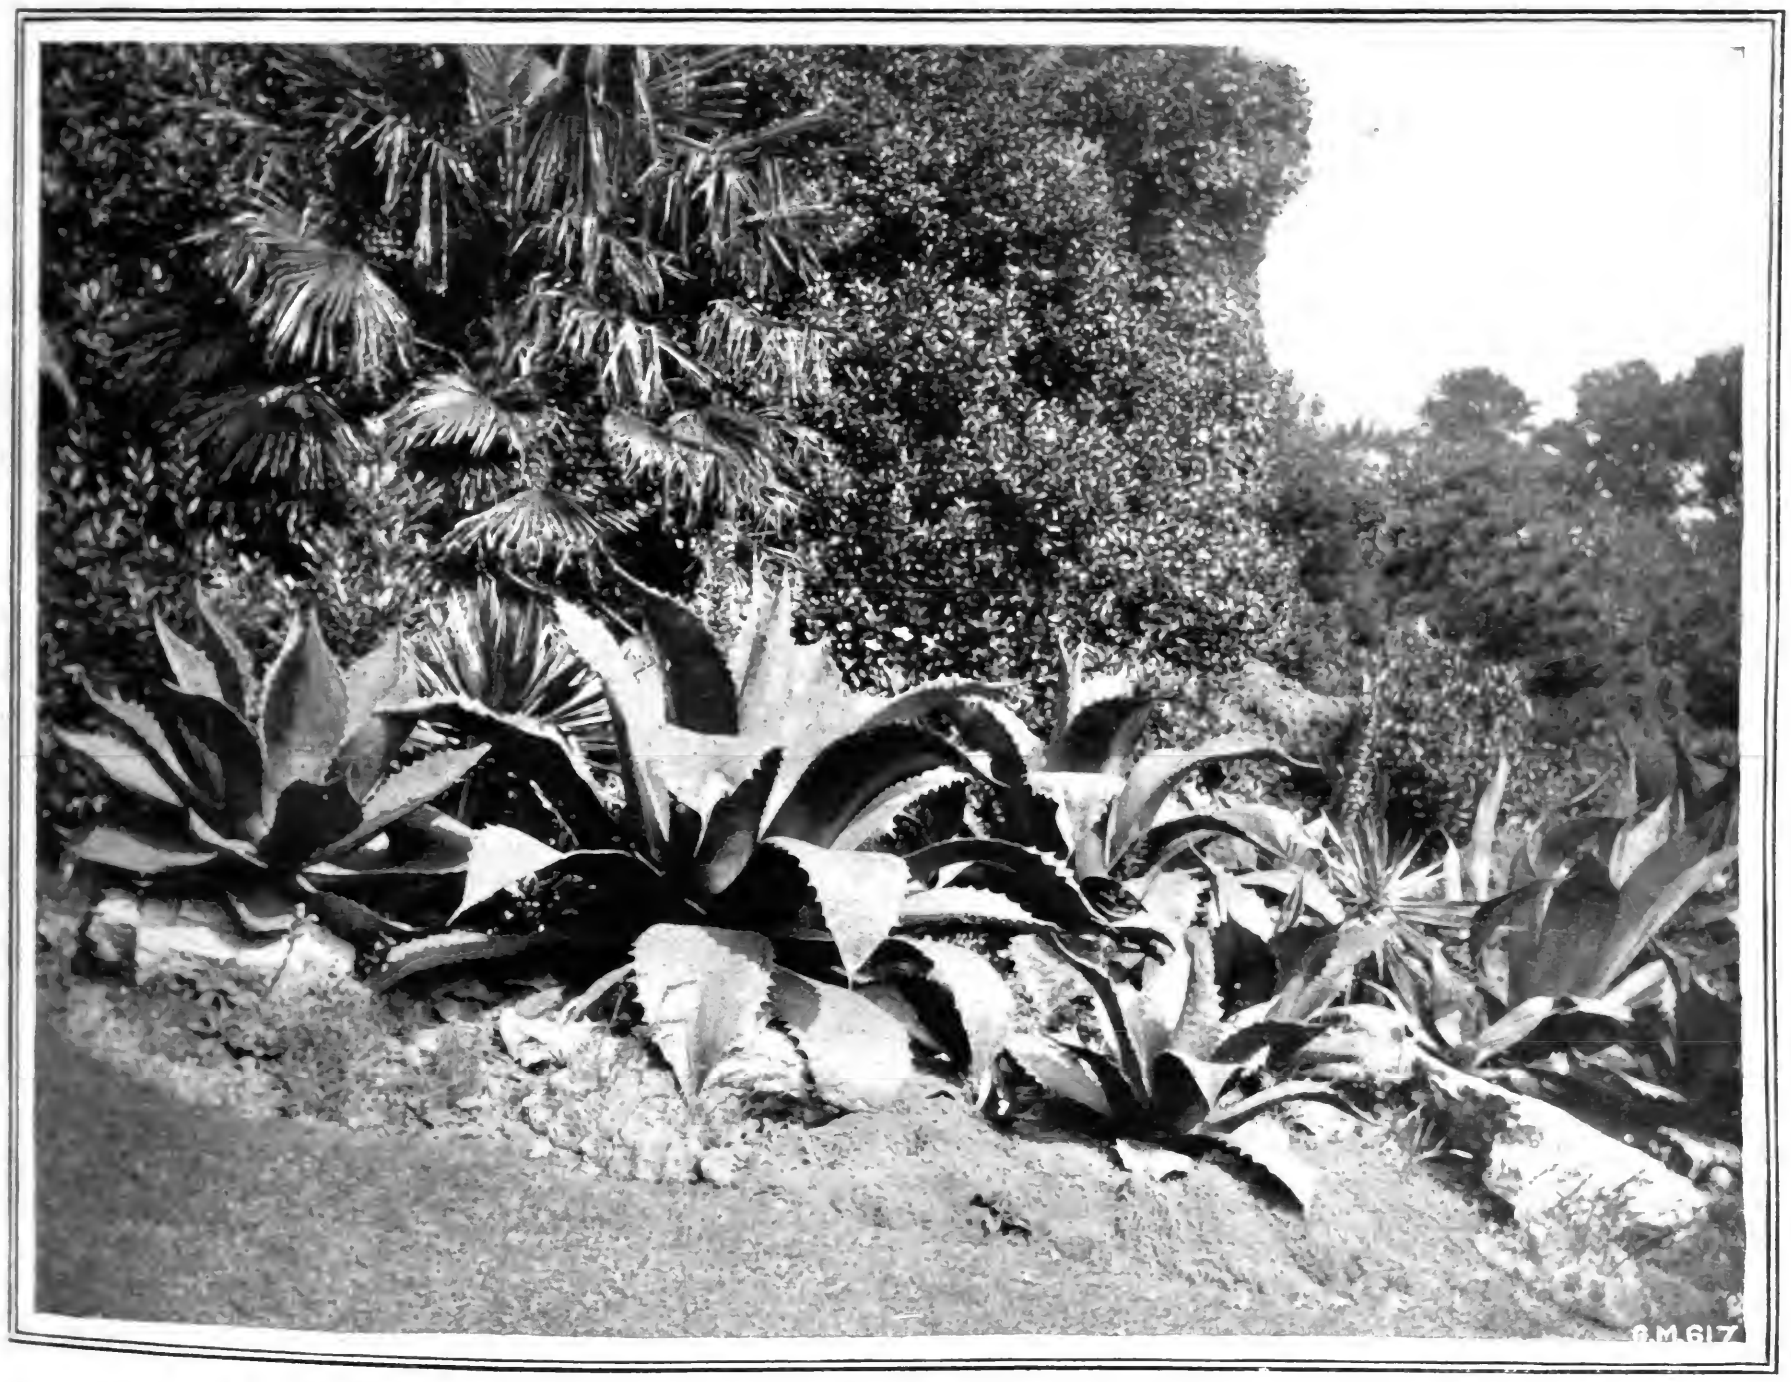
In the severe frost of February last year the specimen at Kingswear was cut to the ground, but in April two new shoots were thrown up, which grew to a length of about twenty feet in the season, and in the autumn two more shoots were produced. It is a splendid subject for a cool structure. In the Temperate House at Kew there is a fine specimen, which has reached the glass roof at a height of over thirty feet. This species was introduced into this country exactly two hundred years ago.

WYNDHAM FITZHERBERT.

Kingswear.

THE DOUBLE-FLOWERED BLACKTHORN.

The common blackthorn, Prunus spinosa, is such a familiar bush in hedgerows and coppices that we should hesitate about introducing it to gardens, although it is a very beautiful object during March and early April when covered with its pretty white blossoms. But there is a double-flowered form which is quite worth garden room, and a well-flowered specimen always excites admiration. Of rather dense, bushy habit, it, like the type, forms stiff, spiny branches and short, spur-like growths, from which the white flowers, which are about one-third of an inch across, appear with great freedom, and retain their freshness and beauty as long again as do those of the single-flowered forms.



A FINE GROUP OF AGAVES IN THE OPEN AT ROZELLE, TORQUAY.
The largest specimen is 5ft. 3in. high, and over 6ft. across, and one of its leaves is 15in. broad.

Unfortunately, it is a rather difficult shrub to propagate, and grafting or layering has to be relied on, therefore there does not appear to be any possibility of obtaining it in quantity, otherwise it would form a most effective plant for massing on dry banks. As it is, the usual method is to cultivate it as a specimen bush, or as a group in a shrubbery, for both of which purposes it is very well adapted. By using it as a specimen bush, and planting the ground beneath with the later chionodoxas or early muscaris, an effective contrast is provided between the white flowers of the plum and the blue carpet. Like P. spinosa, the double-flowered blackthorn is not very particular regarding soil, although it thrives most satisfactorily in that of a loamy nature. This shrub may be planted in any good garden soil with the assurance of it proving satisfactory.

W. DALLIMORE.

GROUPING CONIFEROUS TREES.

A selection of conifers is a means of adding considerably to the attractiveness of a garden during the winter months. Where there are suitable positions in which to plant them very pleasing effects can be created, and it is doubtful whether any classes of trees makes such a telling feature for so many months of the year. Where conifers can be placed on slightly rising ground they are probably seen at their best, and when viewed across a small valley or widened dell they are certainly very attractive.

There are several important points to be taken into consideration when grouping conifers. Firstly, it is necessary to have variety; secondly, to group species of similar character together; and, thirdly, to avoid overcrowding. It is desirable to plant those with dark green foliage as a background for others, but occasionally a specimen with a glaucous or golden hue may be allowed beyond these, so as to avoid formality

I propose only to deal with some of the choicer conifers, and those of medium growth, as these kinds are the most desirable for the garden.

Cupressus Lawsoniana is well known, and its robust growth and conical outline render it most suitable for a central position. C. L. erecta viridis can be associated with it, and is an erect-growing form, with short, crowded branches of upright growth, and bright green foliage. The tree has a distinctly tapering outline, and as it does not spread much in comparison with its height, it can be fairly closely planted. Intermixed with this variety C. L. Allumi is very telling, its dense columnar habit of growth, short rigid branches, and foliage of a distinct steel-blue shade, render it very telling against the bright green foliage of the previous variety. C. L. lutea is probably the most effective of all the cypresses, for the young growths are a rich yellow, which, combined with its regular habit of growth, makes the tree especially handsome. To complete the combination C. macrocarpa lutea must also be sparingly used. It is a rapid growing tree, of columnar habit, with erect branches and plumose foliage. A well-arranged group of these varieties makes a fine feature when they have attained fair proportions, but in arranging them it is desirable to let the green predominate.

Several of the Silver Firs and Spruce Firs are very effective when planted in combination, but in the case of these it is essential to allow them ample space to secure the most pleasing effects. When thinly grouped in conjunction with a few other subjects, they produce a fine impression when viewed from a short distance. Abies lasiocarpa makes a handsome tree. Its branches are produced horizontally, and are a little crowded; while the leaves, which are brought almost erect by a twist at their base, are rather closely set, and have two whitish bands which gives the tree a distinctly glaucous appearance. A. pungens glauca is suitable for association with this. Owing to its compact outlines and rich glaucous foliage, which often varies in intensity, it is the finest of the Spruce Firs for garden decoration. A. nobilis is a distinct and handsome tree, with horizontal branches that ascend towards the tips. The leaves are sometimes glaucous above, with two whitish bands below. This species frequently grows rapidly until it is about thirty years old, when the top often dies, with the result that the tree becomes dwarfed and flat-topped. The cones are very large and handsome.

Abies Nordmanniana is suitable for planting with the foregoing. It forms a stately specimen, and has slightly ascending branches, while the leaves are a bright green, and have two glaucous bands on their lower sides. A. homolepsis takes an important place as it is a massive tree, but it does not attain a great height. The branches are ascending and of sturdy growth, while the two whitish bands on the under side of the leaves give the tree a slightly glaucous appearance. A. Mariesi is a fine species of rather short, but sturdy habit. It is a compact grower, and its deep violet-blue cones are especially picturesque.

Sequoia gigantea makes fairly good growth in rich loamy soil, and where it succeeds becomes a handsome specimen. Cedrus Deodara and C. Libani are too well known to need description, but they are very desirable in a grouping scheme, as they form a magnificent background. C. atlantica glauca looks its best when planted alone on a wide-spreading lawn. Where space permits a group of eight or ten trees will create a fine feature, especially when viewed in the sunshine, which shows up their silvery-grey foliage to advantage. This variety has its branches irregularly disposed, and they are often of unequal length, which gives the tree an informal outline.

Retinospora squarrosa is one of the most beautiful conifers, and has delightful silvery foliage. It is frequently of irregular outline, and is suitable for the forefront of shrubberies, where it can be used in conjunction with A. filifera aurea, a slender-growing and graceful subject, with the terminal growths a light golden yellow. Cryptomeria elegans is suitable for a similar position. It has short horizontal branches, with acuminate green leaves that change to a telling bronzy crimson in the late summer. Cupressus Lawsoniana Silver Queen associates well with these latter subjects; and it is similar in habit to C. L. lutea, only the young growths are a rich cream colour.

J. Gardner.

Batsford Park Gardens.

Rhododendron Fosterianum.—This is one of the most striking of the various white-flowered rhododendrons that require the protection of a greenhouse. It is a hybrid between Rhododendron Edgeworthi, a species which has played a prominent part in the production of many valuable varieties, and R. Veitchianum, a native of Moulmein, and remarkable for its large, massive flowers, with, in some instances, the edges of the petals very much crimped. The fine R. Fosterianum is vigorous in growth, and the shoots should be stopped when young in order to ensure a bushy habit. The flowers are very large, widely expanded, and in colour pure white with a yellow stain in the upper part of the interior. They inherit to a great extent the fragrance of R. Edgeworthi, which has imparted that desirable feature to most of its offspring.—T.

ORCHIDS AT CHELTENHAM.

James Cypher and Sons, Exotic Nurseries, Cheltenham, is a title and address that has been for many years familiar to the readers of the Gardeners' Magazine, and, indeed, to horticulturists throughout this and other lands. The mention of the town of Cheltenham to a gardener brings the name of Cypher immediately to his mind, and with it are associated choice orchids, and lovely groups of stove and greenhouse plants, for it scarcely requires to be said that year after year Messrs. Cypher and Sons take a foremost position at all the leading shows in the big group classes, and we sometimes wonder whether these attractive classes would long survive the absence of Messrs. Cypher from among the competitors. However, we will not dwell upon this point, but express the hope that the firm and its present members will be with us many a year yet to add still further successes to their splendid record as exhibitors, and also to install many new, or enrich already established collections of orchids in the gardens of Britain. That they have the material to accomplish either of these tasks our visit to their nurseries afforded ample proof, for there are orchids of all kinds in the best possible condition, and a tour in the compact range of about a score of well-built and well-stocked houses is capable of affording an infinity of pleasure. There are big specimens that testify to the careful and skilful treatment that has been meted out to them; tiny, but healthy, young plants for growing on; choice rarities that at once appeal to the connoisseur; and hosts of the cheaper, easily-grown kinds, suitable for the beginner or the amateur of modest aspirations.

The erroneous idea is even to-day prevalent that all orchids are expensive luxuries that only the rich may touch; and it will therefore be well to emphasise the fact that plenty of really beautiful orchids are as cheap as most other greenhouse plants, and are as easily cultivated as fuchsias or ferns. As a matter of fact, there are listed in Messrs. Cypher's catalogue no less than 240 different orchids that may be obtained at prices not exceeding five shillings a plant, so that one may form a quite respectable collection of orchids with an outlay of a few pounds. It is without doubt the wisest course for a novice to start with these cheaper kinds, waiting until some experience has been gained before venturing with the rarities. The cypripediums are generally recommended as especially suitable for beginners in orchid culture, and it is not surprising that at Cheltenham this popular family takes a prominent place, there being many thousands of plants of various sizes and wonderful variety. The ever-popular Cypripedium insigne and its many varieties claim first attention. The varieties Chantini, delicata, and montanum are among the cheapest, but not the least beautiful, members of the family; whilst choicer forms are found in Peacock, Henry Elwes, John Cypher, and Sanderianum. C. Lawrencianum, var. Hackbridgensis, is a ten-guinea orchid worth its money, and the chaste flowers of C. Leeanum Purity are of exquisite beauty. Messrs. Cypher have a splendid stock of C. Fairieanum which they rightly describe as "a little gem," and it is indeed an orchid one never tires of recommending as worthy of a place in any collection. Those who admire a pure white orchid may seek C. niveum, while the hybrid C. Gravesæ, delicately spotted with rosy-purple, possesses the charm of distinction that delights the connoisseur. A delightful hybrid resulting from a cross between C. Chamberlainianum and C. insigne is named Louisa Fowler. The fact that two or three flowers may be seen on one stem is a strong point in its favour.

It will not do to linger longer over the cypripediums, for the odontoglossums, especially the varieties of O. crispum, demand equal attention. Few will dispute the assertion that the odontoglossums have made greater advances than any other family of orchids since growers took up the raising of

seedlings at home. By careful selection of the best imported forms as parents, and by growing and intercrossing, simply wonderful improvements have been made both in the form of the flowers and the bewitchingly beautiful colour blotches that overlay the white ground and constitute the great charm of the best of the home-raised varieties. At Cheltenham one sees many of these gems, and the only reason for not mentioning their names is the difficulty that would arise in determining which should be omitted. There is, however, but little need to urge the cultivation of odontoglossums, for surely no one who grows orchids at all can long resist their strong claims for attention. The old favourite Odontoglossum grande never fails to make a strong appeal, and other good members of the family are O. triumphans and O. Pescatorei. Passing along from house to house, with note-book in hand, the names of large-flowered, richly coloured cattleyas, laelio-cattleyas and lælio-cattleyas, golden-yellow oncidiums, with the most graceful sprays of flowers nature, aided by man's scientific care, can produce, are jotted down. Epidendrum Imschootiana is an orchid that should not be overlooked; and, indeed, either in or out of bloom, are found in the several structures worthy representatives of every family of orchids in cultivation.

Those in search of something out of the ordinary run may, with advantage, turn to the quaint little Bulbophyllum barbigerum, with tiny sensitive flowers, and to the Epidendrums, lycastes, and the attractive Oncidium Krameri with butterfly-like flowers of rich colours.

Some of the sophronitis hybrids, also, are very interesting and attractive, whilst, of course, dendrobiums will always appeal to those who want neat little flowers for button-holes or sprays. At the time of our visit the calanthes, of which large quantities are grown at Cheltenham, had not long been potted, but they were starting well away, and showed every sign of doing as well as could be wished. There were some grand spikes of the handsome Cymbidium Lowianum, and plenty of other subjects to make their respective houses bright and attractive.

In bringing these notes to a close reference must be made to the splendidly developed greenhouse plants for which Messrs. Cypher and Sons are so famous, and are nowadays so rarely met with in nurseries. Probably almost every reader of the GARDENERS' MAGAZINE has at some time seen the magnificent statices, ericas, bougainvilleas, and clerodendrons this firm has for well nigh half a century exhibited at the leading shows, and it will therefore be no surprise to read that at the nurseries there are lofty houses filled with these and with big palms, and richly-coloured crotons, together with plenty of young plants coming along to take the place of the specimens that sooner or later must succumb to the wear and tear inseparable from repeated journeys to and from shows, and to meet the ordinary requirements of business. There is an irresistible magnetism about these big, shapely specimens to anyone who remembers even the closing days of their glorious reign, when no gentleman's establishment was considered furnished without its collection of such plants as we have mentioned, and when no man was considered a good gardener who could not propagate, grow, and train either ericas, azaleas, dipladenias, or ixoras. It is good to know that the art is not yet dead, for, at any rate, Messrs. Cypher can produce specimens as of yore. There were some massive specimens of Anthurium Wardi, Ixora Duffi, and Clerodendron fallax, and among the smaller furnishing plants so useful in the groundwork of ornamental groups, that elegant little Japanese shrub, Nandina domestica, was particularly noticeable, although many another little decorative plant would, were it not for the overwhelming power of the orchids, have been deemed worthy of mention in a notice of the Cheltenham Exotic Nurseries.

VISITOR.

A DISPLAY OF CALANTHES IN MESSRS. J. CYPHER AND SONS' NURSERIES, CHELTENHAM.

WINTER-FLOWERING BEGONIAS.

Plants of the B. Gloire de Lorraine group, having been slightly reduced at the top after flowering and rested, will, if given warm, moist, and shaded conditions, now produce plenty of young growths from the base. Discard stem cuttings, and select clean fresh growths from the base of the plant. We prefer to root them in sand, as recommended for euphorbias, always inserting more than are actually required, so that we may have a sufficient number of those that will grow freely and break naturally. They root freely in a short time in the propagating case, and may then be potted singly in small 60's, using great care not to damage the young roots, nor to pot too firmly. If space permits they may be kept close in the propagating frame for a few days after potting. Afterwards they should be grown in a shaded house, preferably on a damp base, in a temperature of 65 degrees by night, rising to 75 degrees in the day, with a rise by sun heat after closing; syringe the plants, and remove the shading in the afternoon. On mild nights throughout the growing season we prefer to allow a little ventilation.

H. PRIME

WORK FOR THE WEEK.

CONSERVATORY AND GREENHOUSE.

SWEET PEAS.—The plants which were raised last autumn for flowering in the spring are now showing their flowers. Keep them well supplied with water, as the pots are now full of roots. Liquid manure and soot-water must also be liberally applied. They must still be given abundance of air day and night, and when in flower shade them during the hottest part of the day.

CELOSIAS.—The young plants must not be checked in any way until they are placed in their flowering pots; therefore, as soon as the young seedlings are large enough to handle pot them up singly into small pots. Keep them growing in a mean temperature of 65 degrees. A moist atmosphere is essential until the plants are approaching their flowering stage. On no account let them suffer for want of moisture at the roots, nor allow them to become pot bound until they are given their final shift.

PELARGONIUMS.—The plants which are being grown for blooming in autumn and winter must be pinched to encourage a dwarf, bushy habit. Keep them growing on a shelf near the glass in a light, airy structure. The earliest batch of the fancy kinds, which are now showing their flower buds, must be liberally supplied with stimulants. If aphis attacks the foliage fumigate lightly with a nicotine compound. See that the growths are neatly and securely staked.

BOUVARDIAS.—The young plants which have been rooted this season must be potted singly in small 60-size pots, using a light compost. Keep them growing freely in a moderately warm, moist atmosphere. They will require stopping two or three times to encourage a branching habit. When they have been placed into their flowering pots they must be gradually hardened off and eventually plunged in ashes in a cold frame for the summer.

ISOLEPIS GRACILIS.—This is a splendid little plant for furnishing the edges of groups or stages in the conservatory and greenhouse. Old plants are not so neat and effective as young ones, therefore they should be divided and repotted every spring. Place them in a warm, moist atmosphere for the first few weeks to encourage quick growth. Three and a-half inch pots will be quite large enough to grow them in.

CLIMBING ROSES.—As soon as the plants have passed out of flower they must be encouraged to make growth. Cut back the old flowering wood, leaving plenty of room for training the young wood over the trellis. Perle des Jardins is one of the most useful for growing over the roof of a cool greenhouse, but it must not be cut so hard back as is the case with some varieties. Growth of moderate strength will produce the most flowers. Fortune's Yellow is probably the most useful rose grown under glass when well managed. At the present time we are cutting daily dozens of beautiful flowers of this variety with stout stems 18 inches long. After blooming the old flowering wood is cut hard back to encourage young growths from the base. These are trained over the trellis about one foot apart.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

PEACHES AND NECTARINES. — The mild weather has brought forward all kinds of fruit buds quite a fortnight earlier than ever I have known them. Although apricots and peaches are fairly studded with flowers, these are not so strong as I should like to see them, especially the apricots. Probably this is because the trees have had little rest during the autumn and winter. The flowers will need every care and attention should a severe spell of frost occur. Remove blistered leaves and burn them, and do not be in too great a hurry with disbudding; and keep the foliage clean should aphis appear.

HORIZONTALLY-TRAINED TREES. — Where corresponding tiers of branches are required on older trees, dormant buds may be made to break by cutting somewhat deeply into the wood just above the break required, with a sharp-edged knife or a small pruning saw. This is what is termed notching, and should be practised on all trees where well-placed buds are likely to remain dormant. In some cases this may have to be done the following spring; the first season, as a rule, the bud will be found to plump up, and the next season quite a strong shoot will be the result. All ill-placed buds should be rubbed off, thereby directing strength to the shoots and branches required to form an evenly-balanced, fruitful specimen.

STRAWBERRIES. — All beds should be thoroughly cleared of weeds, and mulched with stable litter, if obtainable, placing the cleanest straw round the plants; the rains will have washed it quite clean by fruiting time. Beds prepared expressly for early fruits should receive first attention; our beds occupy borders in front of the glasshouses, and these we bed down with plenty of strawy material to be in readiness for the fruits later, and also for the protection of the flowers during sharp frosts. I have repeatedly saved the flowers from damage, and probably the loss of a whole crop of fruit, by simply taking a handful of the strawy material (when the frosts have threatened to be keen) from between the rows and laying it over the trusses of flowers. When the straw is at hand a large quantity of plants may be covered in a very short time. Make ready any site intended to be planted with forced plants, so that they may not be allowed to remain longer than is necessary after hardening. These should yield heavy crops next year, and sometimes very good strawberries are produced in the October following planting. Strawberries require good soil and a firm grip, and ample room to develop their leaves and produce sturdy crowns by the end of the season.

GRAFTING.—Continue the work of grafting where such remains to be done. By this date the sap should be flowing freely, and if the scions are carefully inserted and waxed, tied, and clayed over, no difficulty will be experienced in inducing them to grow. If the trees are of good size and thickness, crown-grafting should be practised, inserting two or three scions, according to the size of the stock. Horizontally-trained trees should have two scions placed on each tier, one on the upper side and one on the under. Small trees may be whip-grafted, using proper grafting wax. Good varieties of most kinds of fruit trees, when aged and clothed with long, useless snaggs, may be brought into good bearing by cutting away the old branches and selecting a fresh stock of young wood suitably placed. Trees thus treated will in a very short space of time furnish good, healthy branches, and continue to fruit for many years. — H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

PARSLEY.—Plants raised in heat, pricked out in boxes, and duly hardened, may now be planted out at one foot apart. To obtain the best results the soil should be deeply stirred and enriched with well-rotted manure; previous to planting, dress the surface with soot and wood ashes, and rake in. If slugs are troublesome place a ring of cinder ashes around each plant as the work proceeds. Where an early batch of plants is not raised in heat, sow seeds now in the open ground; the rows should be one foot apart, and when the young plants are forward enough to handle thin out by degrees until they are one foot apart in the row. Occasional dustings of soot are most helpful to this crop.

CAULIFLOWERS.—Continue to plant out the various sowings as soon as they become ready. Lift with good balls of earth and plant firmly on well-manured and deeply tilled ground. It may be necessary to place a ring of finely-sifted cinder ashes round each plant as a protection against slugs. Further sowings should be made for successional crops. Magnum Bonum, Early Giant, Autumn Giant, and Sutton's Mammouth are excellent varieties.

MAINCROP POTATOES.—Providing the ground has been duly prepared and the surface freely stirred, planting may proceed whenever the soil is in a working condition. Drills should be drawn four or five inches deep, and the sets placed in them twelve to fifteen inches apart, according to the growth of the variety. It is a great advantage to have the sets well sprouted with two or three strong, sturdy shoots; when covering in, be careful to avoid damaging the young shoots. The distance between the rows should be regulated to the requirements of the particular variety. Strong growers should not be cramped for space, and a distance of three feet between the rows may be allotted them. Varieties which make a weaker growth may be given 27 inches to 30 inches. Varieties of proved merit are Snowdrop, Beauty of Hebron, Up-to-Date, and The Factor; the latter variety is one of the very best for baking purposes.

BEET.—If an early supply of beetroot is required, seed of Sutton's Globe or Webbs' Reliance Globe may now be sown, selecting a warm, sheltered position for this sowing. Towards the end of the month another sowing should be made on open quarters, and at the same time a small sowing of a maincrop variety will prove exceedingly useful, coming into use between the early and latest crops.

WINTER GREENS.—The principal sowing should now be made of Brussels sprouts, broccolis, and borecoles of sorts, also a small sowing of an early type of savoy cabbage. If the ground has been prepared as previously advised, it will only require raking to provide a fine tilth. Mark out the beds and sow thinly broadcast, or in drills seven inches apart. As a protection against birds enclose the beds with fine mesh wire netting, placing over the top some ¾-inch mesh fish netting. Mice are often troublesome, and some breakback traps should be handy for immediate use. A sowing of leeks for late use should not be omitted.

GLOBE ARTICHOKES.—About the second week of this month is a suitable time to form new plantations. Globe artichokes require a well-enriched and deeply-dug soil. Procure suckers of a good variety and plant them singly, three feet from plant to plant, allowing four feet between the rows; make the soil about the plants very firm. As a preventive of attacks of slugs, place finely-sifted coal ashes about each plant.—W. Messenger, Woolverstone Park Gardens.

Camellia reticulata.—The blossoms of this camellia are, from their informal nature, quite distinct from most of the forms of Camellia japonica, while their large size also attracts attention. Though an old species, Camellia reticulata largely dropped out of cultivation, but of late renewed attention has been given to it. Apart from the question of flowers, the dull tone of its leafage furnishes quite a distinct feature from Camellia japonica.—T.

CARNATION SHOW.

The SPRING SHOW of the PERPETUAL CARNATION SOCIETY will be held at LEAMINGTON SPA.
APRIL 10th, 12 noon to 10 p.m.
APRIL 11th, 10 a.m. to 5 p.m.
Schedules and particulars from the Hon. Secretary,
T. A. WESTON,
Floradale,
Orpington.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street London, E.C.

EXHIBITIONS AND MEETINGS.

Liverpool Spring Show,

APRIL 2 and 3.

For a good many years the Liverpool Horticultural Society has held spring shows that for variety, beauty, and general interest are not surpassed in the country, and we are glad to record another addition to the long list of successful events the society has organised, for the show held on Tuesday and Wednesday last was in every way satisfactory. Unfortunately, the Corn Exchange, in which the shows are held, has been undergoing alterations entailing the reduction of the space available for the exhibition, and it became necessary to reduce the classes somewhat because of lack of room for exhibits. This was a great pity, but, nevertheless, the show seemed every bit as attractive and beautiful as ever.

There were not only bulbous flowers and flowering shrubs, but a good display of cyclamen, primulas, and cinerarias, and the several exhibits of alpine plants were full of the dainty little gems that are so popular to-day for rock gardening. Trade exhibits were numerous and excellent, not only the local nurserymen showing largely, but many from the south and west brought up of the best.

The winner for four pots or pans of hardy herbaceous and four of bulbous plants was Mr. Geo. Eaton, gardener to W. Tod, Esq., Dry Grange, Allerton, Liverpool. His Dielytra, Astilbe longifolia, and tulip Wm. Pitt were worthy of comment; Mr. E. R. Finch, gardener to W. J. Lockett, Esq., Grassendale House, Grassendale, came a very good second; and Mr. Thos. Hitchman, gardener to A. Earle, Esq., J.P., Childwall Lodge, Wavertree, was third.

Some grand hyacinths were shown, the competition in the principal open classes being keen. The twelve pots of single bulbs with which Mr. Thos. Hitchman secured first prize, had shapely, well-developed, and attractive flowers. The second prize went to Mr. J. W. Barker, gardener to Alderman F. R. Dixon Nuttall, J.P., Ingleholme, Ecclestone Park, Prescot; and Mr. Geo. Osborne, gardener to Drs. Tisdall and Ingall, The Brook Villa, The Brook, was awarded third prize. Mr. J. W. Barker took the lead in the class for six pots, his followers being Mr. Thos. Rigg, gardener to Miss McKean, Wavertree Lodge, Wavertree, for second place, and Mr. Thos. Hitchman third.

Six pots of hyacinths, with three bulbs in each pot, made a nice class. There were half a dozen entries, first prize going to E. R. French, Esq., Grassendale House, Grassendale. Mr. W. Betley, gardener to F. Harrison, Esq., Eton Bank, Hornby Lane, Wavertree, won second prize, Mr. Thos. Rigg bringing up the rear. Mr. Geo. Osborne beat Mr. T. Hitchman for three pans containing ten bulbs, but the flowers in this class were not to be compared with those in the foregoing classes.

There was a very good display of daffodils in pots, five competitors entering for six pots in not less than three varieties. Loo Thomson, Esq., Ailsa Craig, Formby, proved to be the successful exhibitor, showing some splendid pots of Glory of Leiden, Mdme. de Graaff, Van Waveren's Giant, Olympia, Madame Plemp, and Vanilla, all of which were in true character, and beautiful condition. Mr. F. Atkin, gardener to T. W. Wright, Esq., Mossley Vale House, Mossley Hill, had also a very creditable lot in his second prize exhibit, Glory of Noordwyk being especially noteworthy. Third prize went to Mr. E. R. Finch. This gentleman turned the tables on his competitors in the class for twelve pots of single tulips, showing some beautiful flowers, such as Queen of the Netherlands, Holbema, Brunhilde, and Grace Darling. Mr. F. Atkins' second prize set were also good, Pink Beauty, Fabiola, and Proserpine being attractive flowers. Third prize went to Mr. J. Williams, gardener to C. J. Proctor, Esq., J.P., Boscobel, Oxton.

Mr. Williams was more successful with six pots of single tulips, securing first prize. He had Joost Van Vondel, Couleur Cardinal, Sarah Bernhardt, and other charming varieties. Loo Thomson, Esq., followed closely for second place, and Mr. E. R. Finch came third. Mr. Williams again led for double tulips, his flowers being quite in advance of those of his competitors, of whom there were eight in the class. The second and third prize winners were Mr. Thos. Rigg and Loo Thomson, Esq.

Six hybrid amaryllis found three exhibitors, the first prize being awarded to Mr. W. R. Bentham, gardener to A. A. Paton, Esq., Greenbank Drive, Sefton Park. He had a very beautiful crimson named King Edward VII., and a scarlet one named Bobbie Burns was also good. Mr. Thos. Rigg secured second prize, and Mr. E. R. Finch was third.

There has always been strong competition in the classes for specimen plants at Liverpool, and, although it must be admitted that there was a falling off in numbers this year in comparison with what we have seen in former years, still the effect of the whole display of azaleas, rhododendrons, trained roses, and specimen orchids was striking and unquestionably beautiful. Mr. Geo. Eaton, Allerton, showed some magnificent plants of Cœlogyne cristata Lemoniana, and Cymbidium Lowianum, with which he secured two first prizes and the North of England Horticultural Society's silver-gilt medal. Rarely have we seen finer plants than those Mr. Eaton staged; they were a complete mass of bloom, and the plants were perfect pictures of health and vigour. Mr. Eaton had further success with four forced hardy plants, showing Clematis Henryi, Azalea rusticus, a rhododendron, and hydrangea. Again Mr. Eaton won for two callas, big masses, carrying sheaves of flowers.

Mr. Thomas Hitchman's three specimen azaleas won first prize, and well they deserved it. They were broad, evenly-balanced plants, simply smothered in bloom, the colours being bright and clear. For three roses in pots, Mr. E. R. Finch led with trained plants of Hiawatha, Excelsa, and Caroline Testout. Mr. Finch also came first for greenhouse azaleas. There were some big, well-grown ferns staged, especially nephrolepis. Mr. J. McColl, gardener to J. W. Hughes, Esq., New Heyes, Allerton, took firsts for three varieties and also for one specimen, the latter being Goniophlebium subauriculatum, with fronds fully six feet in length.

A SPLENDID SPECIMEN OF CYMBIDIUM LOWIANUM

Exhibited at Liverpool Spring Show by Mr. Geo. Eaton, gardener to W. Tod, Esq., Dry Grange, Allerton. Awarded First Prize.

Mr. Thomas Hitchman's eight vases of cut narcissi, distinct varieties, secured first prize. He showed M. J. Berkley, Sir Watkin, Barri conspicuus, and Madame Plemp very well. Second place was taken by Mr. Geo. Osborne, The Brook. For a basket of daffodils Mr. E. Wharton, gardener to J. Findlay, Esq., Maviscourt, Sefton Park, took the lead with a nice clean lot of flowers arranged just a little too stiffly. The second prize in this class went to Mr. J. Williams.

There were not so many decorated tables as are generally seen at this show, but the half-dozen exhibitors put up very tasteful efforts, and the whole of the tables were bright and attractive. First prize was awarded Miss G. E. Milne, 52, Bridge Road, Litherland, Liverpool, who used salmon-pink carnations, lily of the valley, and a few pieces of Primula malacoides. Mr. J. Williams, Oxton, came second with a delightful arrangement of roses, perhaps just overdoing the embellishment with asparagus. Mr. F. Newsham, Old Hall, Aughton, was third.

NON-COMPETITIVE EXHIBITS.

In their usual corner Messrs. Mansell and Hatcher, Rawdon, Leeds, staged some very attractive orchids. The odontoglossums, which formed an important feature of the group, were as fine as could be wished, both in regard to form and colour, and there were also some very charming little dendrobiums and cypripediums in the group. The ferns shown by Messrs. H. B. May and Sons, Dyson's Lane, Edmonton, were choice and varied in character, and a fine dash of colour on their stand was furnished by some good clematis in several varieties.

Messrs. Barr and Sons, King Street, Covent Garden, London, were exhibitors of daffodils, some extremely pretty varieties being staged. Among the flat-cupped section, Sunrise, Charm, and Crœsus particularly appealed to us, whilst the large, symmetrically-formed trumpets of Boreas and the bright flowers of King Alfred were strong plants in a most interesting exhibit. Daffodils were shown by Messrs. Hogg and Robertson, Mary Street, Dublin, who also staged some brilliant anemones.

Messrs. Young and Co., Hatherley, Cheltenham, showed a beautiful lot of perpetual-flowering carnations, their crimson variety Duchess of Devonshire being remarkably good. This is one of the richest-coloured and sweetest-scented varieties we have. Another pretty group of carnations, with a few choice orchids, came from Messrs. Stuart Low and Co., Bush Hill Park, Middlesex. Mrs. C. F. Raphael, one of the perpetual Malmaison varieties, was conspicuous, and there was also a big vase of Baroness de Brienen, which attracted much attention.

A very pleasing exhibit was that of alpine plants, tastefully arranged by Messrs. Bees, Lim., Mill Street, Liverpool; a number of good primulas, some richly-coloured auriculas, and a patch of Androsace sarmentosa were among the first things to catch the eye, but Viola gracilis, Morisia hypogæa, soldanellas, and daphnes were also very good. Messrs. J. Piper and Son, Bayswater, London, put up primulas of many kinds, as well as some good aubrietias and useful rockery shrubs. A plant of more than ordinary interest on the stand was Corydalis Wilsoni, bearing large spikes of amber-yellow flowers.

Mr. G. Reuthe, Keston, Kent, had some rhododendrons and other shrubs, as well as quite an array of saxifragas and primulas, erythroniums, and other alpines. Messrs. Ker and Sons, Aigburth, Liverpool, had, as was to be expected, a beautiful group of brilliant amaryllis; they also staged a very attractive group of forced flowering shrubs, and some of the newer hydrangeas. A gay group of tulips, lilacs, azaleas, and other seasonable flowers came from Messrs. W. Rowlands and Co., Childwall Nurseries, Liverpool.

A PORTION OF THE FINE DISPLAY OF SPECIMEN PLANTS.
Staged in the competitive classes at Liverpool Spring Show.

Broughty Ferry Horticultural Association.

The ordinary monthly meeting was held on the evening of the 25th ult., with Mr. James Bethel in the chair, when Mr. George P. Berry, Edinburgh and East of Scotland College of Agriculture, gave a lecture entitled "Bacteria and Sterilisation of Soils, and how they affect the Gardener." After briefly alluding to the modern science of soils and the warfare going on between two distinct sections of bacteria—the helpful and the harmful— said the nature and condition of the soil was responsible for the amount of bacteria it contained. An acid soil was charged with harmful bacteria, while a sweet neutral soil promoted fertility from the numbers of helpful bacteria present. Lime was generally deficient in all acidulous soils, and an admirable test for this was found in the use of blue litmus paper, which never failed. In dealing with sterilisation and inoculation of soil, the lecturer spoke very highly of results attained in experiments he had worked out with "creole" in the garden and the use of a portable steam steriliser for potting soil. The effect was clearly demonstrated from a series of lantern slides thrown on the screen.

East Anglian Horticultural Club.

At the March meeting of this club, held at The Boar's Head Hotel, Norwich, Mr. W. Bradbury, of the Ipswich Gardeners' Association, gave a very instructive and educational lecture, illustrated with lantern pictures, upon "Some of the Pests of Fruit Trees and Bushes."

Mr. Bradbury was thoroughly at home, as a practical man, with the subject, and his clear statement, helped by his slides (many of which were his own production), made the subject of deeper interest. Almost the entire range of aphis, mites, sawflies, moths, and such creatures, were touched upon, and their life-history given, with the useful addenda of how to eradicate them.

The exhibition tables were a further educational treat. The keeping qualities of the local-grown apples were very manifest. The first strawberries of the year were at this meeting, and no one who saw it could but be struck with the size of bloom and intensity of colour of the cymbidium brought up by Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., Cringleford.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

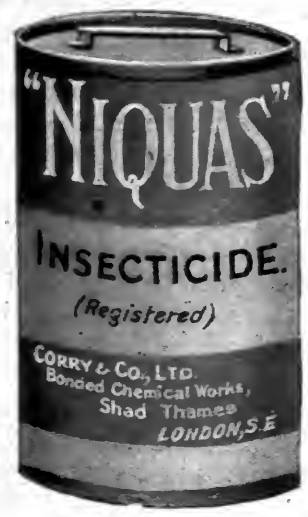
CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

Be sure and purchase "Twentieth Century Gardening," by John Weathers. 300 pages. 1/- nett. To be obtained of all Booksellers.

Full particulars from
THE
CHEMICAL UNION, Ltd, IPSWICH.

IMPORTANT TO GARDENERS AND FRUIT GROWERS

'NIQUAS'
IMPROVED
(Registered.)



The most successful non-poisonous Insecticide of the day.

ITS ADVANTAGES ARE:

Certain death to all Insect Pests.
No possible injury to the most delicate Plant, Flower, or Foliage. It is by far the cheapest Insecticide known. One pint makes ten to twelve gallons for Thrip, Black and Green Fly, etc., whilst RED SPIDER, Mealy Bug, and Scale can be thoroughly eradicated by using "NIQUAS" about double the strength required for Fly.

It is most successfully used by Orange and other Fruit Growers in the Colonies, etc.

PRICES—

Flat, 1/-; Pint, **1/6**; Quart, **2/6**; ½ Gal'on, **4/-** Gallon, **7/6**;
Kegs, each 5 Gallons, **25/-**; 10 Gallons, **45/-**

Ask for Testimonials, of which some hundreds have been received.

SPECIMEN TESTIMONIAL.

From Mr. E. Hubbard, Gardener to G. Hanbury, Esq., Blythewood, Burnham, Bucks. May 15th, 1906.
"I have been using your 'NIQUAS' Insecticide for some years, and can with all confidence say it is the best I have ever used for Bug, Thrip, Red Spider, American Blight, and for all Insect Pests it has no equal. Also for the destruction of Maggots in Marrows by dipping. I have recommended it to my friends generally."

TO BE HAD FROM ALL SEEDSMEN AND FLORISTS.

Manufactured by
CORRY & CO., Ltd.,
BEDFORD CHAMBERS, COVENT GARDEN, LONDON, W.C.

Royal Horticultural Society.

(Continued from page 236.)

some quantity, with odontoglossums, Trichopilea suavis, and a few cypripediums.

J. S. Moss, Esq., Bishop's Waltham; C. J. Phillips, Esq., Sevenoaks; De Barri Crawshay, Esq., Sevenoaks; and Sir Jeremiah Colman, Bart., Reigate, all showed a few orchids, the latter sending a long spike of the yellowish Lessochilus speciosus.

DAFFODIL COMMITTEE.

A number of very beautiful daffodils, including many unnamed seedlings, were well set up by Mr. A. M. Wilson, Shovel. Some of these were superb in form and colour, and Jupiter, with blood-scarlet cup and yellow perianth; Crœsus, Whelp, Hypatia, Gadfly, with flat orange cup and crown; Greeneye, with green base to a yellow crown; the White Trumpeter Mrs. Robt. Sydenham, and the ever-pleasing Golden Buttercup were the most noteworthy.

Messrs. R. H. Bath, Lim., Wisbech, presented many new and rare varieties of daffodils, and had Darwin tulips in superb condition growing in bowls of fibre. Among the daffodils The President, White Pennant, white trumpet and creamy trumpet; Sarabande, a fine poet; Brilliancy, with vivid orange rim to the deep yellow cup; Bernardino, Flame, and a giant pale cream trumpet named Fenland Belle, were all capital things.

Messrs. Sutton and Sons, Reading, were exhibitors of daffodils, and their leading varieties were Southern Star, Homespun (fine), Southern Gem, and Orange Buffer. From the Wargrave Hardy Plant Farm, The Arcade, Liverpool Street, came a small collection of Darwin tulips; the flowers of L'Admirable, Turenne, and Paul Baudy were the best.

Messrs. Barr and Sons, Covent Garden, presented a very striking display of daffodils and tulips. The former were most extensively exhibited, some hundred and thirty distinct varieties being staged. The finest of the newer sorts were Crœsus, Atalanta, Cleopatra, Charm, Orange Gem, Bloodstone, Moidore, Red Beacon, Bride of Lammermoor, a creamy trumpeter; Lord Kitchener, and Sunrise, the latter with a brilliant orange cup. Jasper was also a striking and brilliant variety.

It is always difficult to describe the Rev. G. H. Engleheart's exhibits, as nearly all the flowers are new seedlings, and staged under number only. On this occasion he exhibited over a hundred new daffodils; there were glorious golden Ajax varieties and beautiful bicolors, flat-crowned varieties with yellow or orange crown, long tubular triandrus hybrids—some of purest whiteness and some richest yellow; incomparabilis and Giant Leedsi varieties, and not a few poets of great beauty and purity.

Mr. F. Herbert Chapman, Rye, arranged his daffodils very lightly and prettily. His exhibit contained large numbers of seedlings, as yet unnamed, but also included good blooms of Torch, Castile, Percival, the lovely White Queen, Ethelbert, Mrs. Wolseley, Albatross, Orangeman, Lucifer, and Will Scarlet—a fine lot. Mrs. R. O. Backhouse, Hereford, had a small exhibit of unnamed seedling daffodils.

Messrs. Cartwright and Goodwin, Kidderminster, had a comparatively small display, but they staged fine things in White Emperor (A.M.) of faultless shape and poise; a great golden trumpeter named John of Gaunt; the semi-double Royal Sovereign; Ambrosine, a fine Giant Leedsi, and the rich orange-crowned Chough. Mr. Christopher Bourne, Bletchley, had a very beautiful exhibit of daffodils, and his outstanding varieties were Lucifer, Red Lady, White Countess, the fine new White Emperor, Homespun, the dainty Armorel, Ethelbert, Southern Star, with its orange-yellow crown, and the big double Plenipo.

Daffodils from the Lissadell Bulb Farm, Sligo, were good, and the flowers of Incognita, Lady Edith Foljambe, Seagull, W. B. Hartland, and Flambeau were conspicuous in the collection. Mr. W. A. Watts, St. Asaph, put up a large exhibit of daffodils, but rather crowded his front bunches of Firebrand, Argent, Lucifer, and Doubloon.

Messrs. R. and G. Cuthbert, Southgate, made up a brilliant exhibit of tulips in pots; the flowers were very good.

Among the daffodils set up by Robert Sydenham Limited, Birmingham, the most striking variety was Gold Coin.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Brasso-cattleya Heatonense Canary, and to Cypripedium Roundhead, from Lieut.-Colonel Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Gloucester; to Cymbidium Humbolti, from Messrs. Charlesworth and Co., Haywards Heath; to Odontoglossum eximium Warnham Court var., from C. J. Lucas, Esq. (gardener, Mr. Duncan), Warnham Court, Horsham; to Laelio-cattleya Dominiana Southfield var., from W. Waters Butler, Esq., Southfield, Birmingham.

Award of Merit.—To Odontioda Cooksoniæ Ralli's var., from Pantia Ralli, Esq., Ashtead Park, Leatherhead; to Cattleya intertexta var. Juliette, from Mons. Firmin Lambeau, Brussels; to Odontioda Keighleyensis ignita, from Messrs. J. and A. McBean, Cooksbridge, to Narcissus White Emperor, from Messrs. Cartwright and Goodwin, Kidderminster; to Douglasia lævigata, from Mr. Maurice Pritchard, Christchurch; to Carnation Mrs. Wilfred Gott, from Messrs. W. Cutbush and Son, Highgate; to Primula viscosa Othello, and P. v. Jean Douglas, from Mr. James Douglas, Great Bookham.

MEDALS.

Gold.—To the Hon. Vicary Gibbs (gardener, Mr. E. Beckett, V.M.H., Aldenham House, Elstree, for a rock garden exhibit.

Silver Gilt Flora.—To Messrs. Barr and Sons, Covent Garden, for daffodils; to Mr. A. M. Wilson, Shovell, Bridgewater, for new daffodils.

Silver-gilt Banksian.—To Mr. Christopher Bourne, Bletchley, for daffodils; to Messrs. R. and G. Cuthbert, Southgate, for tulips in pots.

Silver Flora.—To Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Mr. F. Herbert Chapman, Rye, for daffodils; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to H. T. Pitt, Esq. (gardener, Mr. Thurgood), Roslyn, Stamford Hill, for orchids; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. G and A. Clark, Dover, for primroses, etc.; to Messrs. W. Cutbush and Son, Highgate, for carnations and flowering shrubs; to Mr. Maurice Pritchard, Christchurch, for hardy flowers; to Mr. G. Prince, Longworth, for roses.

Silver Banksian.—To H. S. Goodson, Esq. (gardener, Mr. G. Day), Fairlawn, Putney, for orchids; to Messrs. R. H. Bath, Lim., Wisbech for daffodils and tulips; to Robert Sydenham Limited, Birmingham, for daffodils; to Mr. W. A. Watts, St. Asaph, for daffodils; Mr. James Box, Lindfield, for rock garden; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to Messrs. Stuart Low and Co., Bush Hill Park, Enfield, for acacias and carnations; to Messrs. H. B. May and Sons, Edmonton, for clematis, etc.; to Messrs. Paul and Son, Cheshunt, for lilacs; to Messrs. Pipers, Bayswater and Barnes, for rock garden; to Messrs. James Veitch and Sons, Chelsea, for cyclamens, etc.

Bronze Flora.—To Messrs. Bakers, Wolverhampton, for alpines; to Mr. Clarence Elliott, Stevenage, for alpines; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons; to Mr. A. Hemsley, Crawley, for hardy flowers; to Messrs. G. Jackman and Sons, Woking, for hardy flowers; to Messrs. Wm. Paul and Son, Waltham Cross, for roses; and to Lissadel Bulb Farm, Sligo, for daffodils.

OBITUARY.

MR. ANDREW KINGSMILL.

We greatly regret to record the death of Mr. Andrew Kingsmill, which occurred somewhat suddenly at his residence, The Holt, Harrow Weald, on the 29th ult., in his 71st year.

Mr. Kingsmill, who was one of the leading amateur horticulturists of the present day, commenced life as a schoolmaster, and, after a short experience of school work, entered the Civil Service, and for some time occupied a position in the Post Office. Receiving in 1865 a nomination for the Bank of England, he went to Threadneedle Street, where his remarkable abilities in connection with finance soon became evident, and in the course of the next thirteen years he attained a high position. In 1878 he was appointed the first London manager of the British Linen Bank, where he specially distinguished himself, and its present position in London is regarded as largely due to his ability and energy during the 24 years it was under his management.

Taking a keen interest in gardening, Mr. Kingsmill built himself a residence and formed gardens, at once interesting and beautiful, in a part of the old woods of Bentley Priory. The gardens were wholly of his own planning, and, while quite distinct in their main features from those of the conventional type, they were quite free from the eccentricities that sometimes appear when there is a deviation from the customary lines. Within the delightful gardens were borders of herbaceous plants, rockeries, beautiful trees and shrubs, choice bulbs, and climbing and other roses in abundance. On every side there was evidence not only of a strong affection for beautiful plants, but of a thorough acquaintance with the finest kinds in the several classes. On his retirement owing to ill-health in 1902, Mr. Kingsmill indulged his taste for travel, and for many years he and Mrs. Kingsmill travelled much abroad, bringing back many plants remarkable for their beauty and interest for The Holt gardens, and to a genuine lover of plants nothing could well be more enjoyable than to make a tour through those parts of the gardens where the "finds" had been planted, with Mr. Kingsmill as the guide. His acquaintance with the large number of plants that have a home in the gardens was remarkable, for he was personally acquainted with every one, and could at once locate any particular kind, and give everything of interest that was associated with it.

Mr. Kingsmill was long a member of the Floral and Daffodil Committees of the Royal Horticultural Society, and was one of the directors of the Royal International Horticultural Exhibition of 1912. An illustrated account of The Holt Gardens was given in our issue of August 22, 1908.

THE LATE MR. ANDREW KINGSMILL.

MR. M. MOODY.

We regret to learn of the death on Wednesday, March 10, of Mr. Mark Moody, who for twenty-seven years was head gardener to F. Du Cane Godman, Esq., at South Lodge, Horsham. Four years ago he retired and took up his residence in Horsham. Mr. Moody was 69 years of age, and a native of the Isle of Wight. During the last eighteen months he was a great sufferer. He was a most capable gardener, and held in the greatest respect in the Horsham district. To the allotment holders he acted as guide and friend, and they deplore deeply the loss of the fatherly interest he took in their work. The body was cremated at Woking on March 14.

"Sweet Peas and Their Cultivation," by C. H. Curtis, is a compact and very readable Guide to the culture of this lovely and fragrant flower. Mr. Curtis, who is Hon. Secretary of the National Sweet Pea Society, deals fully and practically with its varieties, culture, and diseases. The book is well illustrated, and can be obtained from our publisher for 1s. 2d. (cloth 1s. 9d.), post free.

ANSWERS TO CORRESPONDENTS.

VEGETABLE MARROWS.—E. H., Ripon: We have rarely been successful with vegetable marrows, and this is particularly annoying when one is fond of the vegetable and is told on every hand that nothing could be easier to grow. We generally raise our plants in heat early in March, and plant them out as soon as possible in May, protecting them at night by means of boxes. Is there anything wrong in this procedure?—Under ordinary conditions early in March is about a month too early to raise vegetable marrows in heat, and we have a shrewd suspicion that your plants have become drawn and starved some time before planting, and have never properly recovered from the check. Sow seeds at once in gentle heat, pot the seedlings singly into 60-sized pots when fit to handle, and presently pot them into 48's, using fairly rich soil for the purpose. Directly the roots push through the soil in these larger pots give cooler quarters. Plant out during the last week in May or the first week in June, protecting them at night with pots or boxes until all fear of frost is over. Marrows like rich, firm soil, well drained, and a warm, sunny position. When growing freely they need plenty of moisture and liquid manure. The fruits should be removed as soon as fit for use, as nothing distresses the plants more than a number of fruits forming their seeds.

BRANCHED CACTUS.—S. P. R., Aylesbury. The description sent is hardly sufficient to enable us to determine what kind of cactus or succulent plant you possess. We shall be obliged, and better able to help you, if you will send a rough sketch of the plant, and also one of a portion of growth. We are inclined to think you have a phyllocactus; anyway you have a fine specimen if it carries three dozen growths.

ALPINE STRAWBERRIES.—S. S., Bideford: Kindly tell me how to proceed for the production of alpine strawberries late in the season.—Sow seeds, obtained from a reliable source, at once in gentle warmth, and prick out the seedlings into boxes as soon as they can be conveniently handled. Place them in a frame as soon as re-established, and encourage growth without in any way coddling the plants. Before the roots become much entwined transfer the seedlings to large 60-sized pots, and by the time they are thoroughly well rooted in these they will be ready to plant out in well-prepared ground. If the soil is light and the weather warm, mulch the soil between the plants with old decayed manure. It would have been better had a start been made a few weeks earlier.

AMERICAN ASTERS.—L. E. R., Bury St. Edmunds: I obtained a catalogue from an American seedsman who advertised in your pages, and am quite interested in many of the things listed therein. Do you know anything about the American form of the China Aster? These seem to be rather out of the common, and I thought of trying them. —Yes; we do know something about these asters, and hope to publish an article and illustrations dealing with the subject in an early issue. You should test a few of the varieties.

CAPE PELARGONIUMS.—F. L. S., Spalding: I have become interested in Cape pelargoniums since seeing so many of them at the Royal International Horticultural Exhibition of 1912. Until now, however, I have not had an opportunity to take up their cultivation. If there are any special points of difference in their management from that found successful for the usual garden varieties of pelargoniums I shall be glad if you will tell me what they are; but what I especially wish is a list of a dozen distinct species to form the basis of a collection.—Greenhouse culture, freedom from aphis and other insect pests, and a compost of three parts fibrous loam, and one each of decayed cow manure and leaf-mould, with plenty of

GARDENING FOR PROFIT

"COMMERCIAL GARDENING," the entirely new work just published, written by 20 PRACTICAL MEN, demonstrates how you can make more money by growing Flowers, Vegetables, Fruit, Plants, Shrubs, and Trees for Market.

It explains how to grow, what to grow, and where to grow. It expounds the best cultural methods, the best marketing methods, the best book-keeping methods, and the best packing and grading methods.

The work contains the contributions, ideas, and thoughts, not only of the contributors named below, but of many other practical men, who, while preferring the spade to the pen, have yet placed their varied knowledge and wide experience at the Editor's disposal.

While there are gardening books in plenty, this is the only book dealing with **commercial** gardening. It is "commercial" in every sense of the word, because it deals with gardening from the point of view of the man who grows plants for profit. It is also "gardening" in the best sense, because the cultural methods of the best market growers are detailed. It considers gardening from the standpoint of "pounds, shillings, and pence."

SYNOPSIS OF CONTENTS.

General Aspects of Commercial Gardening—The Science of Plant Growing—Methods of Propagation—Science of the Soil—Manuring—Insect Pests—Garden Friends—Fungoid Diseases—Fungicides and Insecticides—Glasshouse Building—Heating Apparatus—Hardy and Half-hardy Herbaceous Plants, Bulbs, and Flowers—Stove and Greenhouse Plants—Ferns—Commercial Fruit Growing—Fruit Growing in Worcestershire, Scotland and Ireland—Fungi Diseases in Fruit—Grading and Packing—Pip Fruits—Stone Fruits—Small and Bush Fruits—Figs—Grapes—Nuts—Melons—Garden Surveying—Levelling and Mensuration—Market Garden Accounts—Trees, Shrubs, and Climbers—Conifers and Taxads—Vegetable Growing for Market—Sweet Herbs and Small Salads—Intensive Cultivation—Index.

Name .....

Address .....

sand, as compost, are the chief points to bear in mind. The slender and less robust grower must have their pots particularly well drained, and overpotting must be carefully avoided. August is a good time to take cuttings, and a cold frame will suffice for their protection until the end of September. An interesting dozen species are—P. capitatum, P. quercifolium, P. cordatum, P. tomentosum, P. radula, P. echinatum, P. citriodorum minimum, P. crispum, P. denticulatum, P. tetragonum, P. inquinans, and P. ardens. P. Blandfordianum, P. multibracta, P. artemesioides, P. saxifragoides, P. zonale, P. peltatum, and P. triste filipendulifolium should also be added as circumstances permit.

SPECIES OF MATHIOLA.—S. T. J., Lewes: In addition to the Ten-week, Intermediate, and East Lothian stocks are there any species of Mathiola in general cultivation?—No; the only species in general cultivation is Mathiola tristis, the night-scented stock. At Kew the species in cultivation are M. coronopifolia, purple; M. incana, parent of the Brompton stock; M. sinuata, red; M. triscuspidata, purple; M. tristis, fragrant during the evening; and M. varia.

BROWN PITH IN ROSES. — M. S. E., Derby: I have just begun to prune my roses, and find that in many cases the wood seems firm, but when cut the centre or pith is of a dull brown colour. This suggests to me that such growths have suffered badly during the winter. Should I cut them back much lower than usual, or leave them a fair length in the hope that the buds may develop?—Where the pith is dull brown the wood is dead, or nearly so, and it would be quite useless to allow such growth to remain. Cut back the stems inch by inch until good sound wood is reached, and then cut clean across just above the next bud.

AYRSHIRE ROSES.—C. L., Corsham: Kindly name half a dozen of the best varieties of Ayrshire roses in your next issue, as I am anxious to plant soon from pots.—The best Ayrshire roses are Dundee Rambler, white, flushed pink; Bennett's Seedling, double, pure white; Queen of the Belgians, double, creamy white; Alice Gray, white, edged pink; Rivers' Ayrshire Queen, reddish-purple; and Virginian Rambler, pinkish-white.

SALVIA SPLENDENS GRANDIFLORA FOR SUMMER BEDDING.—A. R., Notts: Could Salvia splendens grandiflora be used for summer bedding? I had intended to use the variety Glory of Zurich, but have not sufficient plants, but can obtain plenty of S. splendens grandiflora. This latter I have only grown for autumn display in pots, and so do not know whether it is suitable for summer display out of doors.—Treated the same as Glory of Zurich, S. splendens grandiflora will flower out of doors for summer bedding, but it is not the equal of Glory of Zurich for that purpose, as it is not so free blooming. You could purchase small plants of the latter from many of the firms advertising in our columns, and these if potted at once would make good stuff by the end of May or early June, and the expense would not be great.

NAMES OF PLANTS.

R. D. R., Bicester.—1, Rhododendron ciliatum; 2, Opuntia microdasys; 3, Begonia fuchsioides.

N. R., Grantham.—1, Primula rosea; 2, a growth of Prunus Pissardi; 3, Exacum affine; 4, Erica ventricosa.

S. T., Stockton.—1, Odontoglossum polyxanthum; 2, O. crispum, a very poor form; 3, Cattleya Schroderæ; 4, Cymbidium insigne.

F. W., Bromley.—1, Nothoclæna sinuata; 2, Nephrolepis Bausei; 3, Adiantum cuneatum gracillimum; 4, Asplenium caudatum; 5, Woodwardia radicans.

M. C. B., Torrington.—1, Anemone pulsatilla; 2, Omphalodes verna; 3, Anemone hepatica; 4, Forsythia suspensa; 5, Correa cardinalis; 6, Tillandsia usneoides.

Situations Wanted—*continued.*

YOUNG MAN (20) seeks SITUATION as Improver; Inside and Out; 3 years' experience, good references. G. WILLIS, Great Burstead, near Billericay, Essex.

YOUNG MAN (22) seeks SITUATION, local; Single-handed or with help; been apprenticed to Nursery; 3 years' present; private; general knowledge. F. HISCOCK, 5, Rokeby Road, Wealdstone, Middlesex.

YOUNG MAN seeks SITUATION in gardens; little experience; wishing to learn; Bothy preferred; age 18. Apply T. LAMBERT, Kelso, Fetherstone Road, Stanford-le-Hope, Essex.

YOUNG MAN (19), very strong, as IMPROVER; Inside and Out; fair all-round knowledge; Bothy preferred; excellent references. C. K., 39, Second Cross Road, Twickenham, Middlesex.

YOUNG MAN, age 22, seeks SITUATION, Inside and Out; 6½ years' experience in kitchen garden and pleasure grounds; excellent references. H. L. HASLETT, 24, Crebor Street, East Dulwich, London, S.E.

YOUTH (18½) seeks SITUATION as IMPROVER, Inside and Out; 3 years' experience; good references. E. L., 75, Bushey Park Road, Hampton Wick.

YOUNG MARRIED MAN requires Situation as GARDENER (Single-handed or with help); 14 years' experience; has been Gardener and caretaker four years previous; first-class references; highly recommended; understands Pigs and Poultry.—A. BULL, Hatton, Warwick.

YOUNG MAN (17) seeks SITUATION in Gentleman's garden, Inside or Out; three years' good reference; Bothy preferred. Apply, E. CLARK, The Gardens, East Bergholt Place, Suffolk.

YOUTH (17) seeks SITUATION in private Garden under another Gardener. Highgate or Hampstead district preferred. W., 13, Cochrane Street, St. John's Wood.

Situations Vacant.

WANTED, strong active MAN for pleasure grounds, with knowledge of machines and scythe. Also ACTIVE MAN for kitchen garden; willing to help when required; both to take turn with duty. Church of England. Wages to start, 18s. and 17s., with comfortable Bothy. G. HY. SHOEBRIDGE, Nunnery Gardens, Douglas, I.O.M.

WANTED, YOUNG MARRIED MAN for garden as General Labourer. Apply, HEAD GARDENER, Woodside, Chenies, Richmansworth.

PUBLISHERS' ANNOUNCEMENTS.

THE GARDENERS' MAGAZINE may be obtained by order from all Newsagents, price Twopence, every Friday. If any difficulty be found, a copy will be posted weekly direct from the Publisher, 148 and 149, Aldersgate Street, London, on the following terms: Twelve Months, 10s. 6d.; Six Months, 5s. 6d.

INDEX to Volume LV. may be obtained through any Newsagent, price 2d.; or 2½d. post free from the Publisher.

BINDING CASES for binding the 12 months' numbers, green cloth, ornamented in gold, price 2s., post free.

VOLUME LV., bound in green cloth, containing the 52 weekly numbers, 1912. Price 12s. 6d.; by post, 13s. 4d.

VOL. LVI.—No. 3,102. SATURDAY, APRIL 12, 1913.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Experimental Work at Rothamsted.

Seventy-nine years have elapsed since the late Sir John Lawes laid the foundation of the Rothamsted Experimental Station, which, in the course of its activities, has exercised an immense influence for good upon the scientific aspects of agriculture and horticulture, and obtained a foremost position among similar institutions, not only in this country, but of the world. This position it continues to hold, and deservedly so, for at no period in its history has its activities been greater or the work accomplished of more importance to the scientist and practical cultivator. The founder began experiments with various manurial substances, first with plants in pots, and then in the field; nine years later more systematic field experiments were commenced, and the services of Dr. J. H. Gilbert were obtained as director, and the long association then formed only terminated with the death of Lawes in 1900 and Gilbert in 1901. Mr. A. D. Hall, who retired in 1912 to take up an important position on the Development Commission, was appointed director in 1902, and during his occupancy of this position great developments were brought about. Dr. E. J. Russell, who had for some time been on the staff, and had accomplished work of far-reaching importance, succeeded Mr. Hall as director, and is continuing the work in such manner as to leave no doubt as to the station becoming increasingly useful. The report for the past year shows that the field experiments with farm crops were carried on in the same comprehensive manner as in previous years, and that experimental work of special interest to horticulturists was extended. In the laboratory, and in the house devoted to pot culture, a considerable amount of work was carried out in connection with the production of plant food in the soil. As the supply of nitrogenous food frequently constitutes the limiting factor in crop production, this work was largely restricted to the nitrogen cycle; but the other factors were always taken into account, and afforded opportunities for a number of subsidiary investigations. In the course of the investigations it was shown that the production of ammonia and nitrate, two nitrogenous foods of great importance, is largely the work of bacteria, and that in normal soils these organisms are not working at full efficiency. A factor was discovered limiting the numbers of bacteria, and therefore of the amount of decomposition they effect. This factor is biological; it is capable of growth, is put out of action by heat or antiseptics, and can only be set up again by infection from outside. It does not, however, appear to consist of bacteria, and is provisionally identified with the protozoa of which numbers were found in all the soils examined. Partially sterilised soils from which the factor had been eliminated were found to contain larger numbers of bacteria than untreated soils, and to accumulate ammonia and nitrates at a greater rate. Such soils are, as might be expected, more productive.

MR. G. P. BERRY,
General Inspector in the Horticultural Branch of the Board of Agriculture.

Methods are being worked out for partially sterilising soils on a large scale, but instead of setting up field plots for the purpose of discovering a cheap and convenient process, it has been thought advisable to induce market growers engaged in intensive culture to adopt some of the methods known to have given good results. The growers of cucumbers and tomatoes on a large scale have, we learn, responded well to the suggestion, and a number of experiments have been carried out at the station with a view to the solution of some of the problems arising out of the application of partial sterilisation to their particular work. The growers, we are informed, have expressed their interest in a practical way of organising an experimental station to be started in the Lea Valley district, and devoted exclusively to the investigation of problems connected with the glasshouse industry. As the result of the investigations that have been made, the new conception is that the soil organisms may, in relation to the processes of food production, be divided into a useful and a detrimental group. The latter are described as being more readily killed than the former, and conditions that are harmful to active life in the soil tend therefore to reduce their numbers and to an increased activity of the useful bacteria. On the other hand, conditions favourable to active life tend to develop detrimental organisms, and therefore to reduce the useful bacterial activity. By these investigation it has been found possible to render intelligible a number of obscure and paradoxical effects that have hitherto caused much perplexity. The investigations relating to the loss of soil nitrogen are giving results of much interest and considerable practical importance. The decomposition processes in the soil lead to a reduction of the stock of nitrogen; part of the ammonia and nitrates is taken up by the plant and utilised, while part is lost. Drain guage experiments which have extended over 25 years, and are still going on, have shown that about 50lb. per acre of nitrogen compounds, chiefly nitrates, were washed out each year in the drainage water during the earlier part of the period, and about 35lb.

later on. The drain gauges are uncropped and unmanured, and when the last percentage of nitrogen in the soil was determined, the loss of nitrogen was found to be equal, within the error of experiment, to the amount of nitrogen recovered in the drainage water. Under these conditions, therefore, the essential change in nitrogen compounds is confined to ammonia production and nitrification; but on the cropped plots, where large quantities are added, other losses appear to go on, and these are now under investigation. The experiments that are being made for the purpose of testing the effects of poisons on plant growth may perhaps prove of less practical importance than those to which reference has already been made, but they are, nevertheless, of much interest, and cannot well fail to give useful results. The amount of growth a plant makes in a given soil is known to depend on the amount of food supplied, and this relationship forms the basis of the connection between plant nutrition work and soil work. But it is pointed out that a hypothesis is current, and is backed by sufficient circumstantial evidence to make it worthy of consideration, that inorganic plant poisons act as stimulants if supplied in sufficiently small quantities. If, as stated in the report, this hypothesis were well founded, it would introduce a wholly new set of factors into plant nutritionships, and would, in addition, form far more important practical developments. Water cultures have therefore been made to test this hypothesis as completely as possible, and the compounds tested have been copper sulphate, manganese sulphate, zinc sulphate, sodium arsenite, arsenious acid, and boric acid. Of the numerous plants tried barley and peas have given the best result, the boric acid decidedly increasing the growth of the latter. The influence of this acid on the growth of the pea is regarded as raising the question whether boron is in some way advantageous to the plant, and therefore to be considered a nutrient.

Mr. G. P. Berry.—Our congratulations, and the congratulations of our readers, are extended to Mr. G. P. Berry, recently appointed General Inspector in the Horticultural Branch of the Board of Agriculture. The appointment was announced in the House of Commons on Thursday, April 3, by Mr. W. Runciman, the Minister for Agriculture. As horticulturists we have thought, and said, that horticulture has not received the recognition due to it, and that in important appointments in connection with the profession eminent men have been passed over in favour of those whose training and ability did not qualify them for the positions. Now, it would seem, all this is changed, and Mr. Runciman has found that there are men who, by careful study and experiment, have added scientific attainments to a life-long practical experience, and are able, by reason of their general education, to fill the highest positions open to them. We believe that when the applicants for this new post were reduced to seven for the purpose of the final selection all were men possessing wide practical knowledge, a capacity for organisation, and ability to express themselves readily. Mr. G. B. Berry's appointment is, we hope and believe, an earnest of better times, and it should be an incentive to all young gardeners to equip themselves for the openings the future may hold. Mr. Berry had a splendid training at Gordon Castle Gardens, the seat of the Duke of Richmond and Gordon, under Mr. Webster. For some years he was Horticultural Instructor to Armstrong College, for the four Northern Counties. After this he became Horticultural Instructor to the Edinburgh and East of Scotland College of Agriculture, and latterly has been head of the Horticultural Department of this college. Mr. Berry's educational and advisory work has been conducted over a wide area in the East of Scotland, and he has always kept in close touch with commercial fruit growing, market garden operations, and all the latest developments in matters horticultural. He holds the Diploma in Horticulture of the Royal Botanic Gardens, Edinburgh, and certificates of the Herriot-Watt College. He has taken a prominent part in the Northern Counties Fruit Congresses, contributing excellent lectures, and taking part in the discussions, and, on the occasion of the Hexham meeting in 1910, he delivered the opening address. Mr. Berry has unbounded energy, a ready utterance, wide practical experience, and a thorough working knowledge of the sciences that apply to his profession, and he is, therefore, in every way fitted for the new, high, and important position to which he has been appointed. We trust Mr. Berry may have health and strength to carry out his new duties to the satisfaction of all concerned for many years to come. The salary is £400 per annum, rising to £500.

Royal Horticultural Society's New President.—At the meeting of the Council of this society held on the 1st instant, Sir Trevor Lawrence, Bart., K.C.V.O., V.M.H., tendered his resignation of the post of president of the society, to which he was elected in 1884, owing to advancing years and impaired health. His resignation was accepted with the greatest possible regret, and with an expression of the almost overwhelming debt of gratitude which the society owes to him for his long and able guidance of the affairs of the society. At the same meeting Field-Marshal the Right Hon. the Lord Grenfell, G.C.B., G.C.M.G., LL.D., was unanimously elected to succeed the retiring president.

Too Many Flower Shows.—We have many times pointed out that the great increase of flower shows in recent years is by no means a blessing. Much energy and money are being expended to no good purpose upon merely local efforts, and the glorification or pecuniary advantage of a few people. The establishment of horticultural societies of an educational character has our interest and sympathy; such societies, by means of fortnightly or monthly meetings throughout the winter season, and visits to gardens and nurseries in the summer, are able to do excellent work, and if interesting exhibits are encouraged in connection with the winter meetings, that is all to the good. There are too many societies existing solely for the purpose of a summer or autumn flower show. Many exist for a short time, and then collapse, whereas had the energy expended been devoted to a really good district exhibition, interest would have been kept alive, and horticulture advanced. During the past week we have received intimation of the cessation, or suspended animation, of not a few societies, and we believe the cause is to be found largely in the weakening influence of so many purely local efforts. Cardiff should be able to manage a good autumn show, but the losses in 1912 were so heavy that there will be no chrysanthemum show this year. At Leith the re-establishment of a flower show seems hopeless, and, after twenty-four years, there is the prospect of a discontinuance of the Blakenhall Society, which lost over £40 last year. Here are three instances, all wide apart, of failure. Bad weather, lack of interest, and many other things are suggested as reasons for failure, but we believe the real trouble is that there are too many flower shows. Perhaps our readers will give us their views on this important matter.

Spring Flowers at Kew.—Kew is particularly bright and gay just now, the daffodils being prominent in many parts of these fine gardens, notwithstanding the bitter east and north-east winds prevailing during the last week. Hyacinths, wallflowers, squills, anemones, flowering peaches, amelanchiers, the earlier pyrus and prunus, forsythias, magnolias, hardy heaths, saxifragas, and hardy primulas are among the more important of the subjects now in flower. Those interested in spring flowers should endeavour to visit Kew just now.

The Origin of Life is a subject that has exercised the minds of the greatest thinkers of all ages, and, though old, it is perennially new. The Rev. Professor G. Henslow, M.A., V.M.H., will discuss this fascinating subject at three o'clock on Tuesday, April 15, at the Royal Horticultural Hall, Westminster, and his lecture is entitled "The Origin of Life: Why it is Undiscoverable."

Xanthophyll in Leaves.—About twelve months since Drs. Willstätt and Escher announced their discovery of the similarity of lutein, the yellow pigment of yolk of egg, to, if not identical with, the xanthophyll present in leaves. Other animal pigments have since been investigated, and Dr. Escher states that the yellow pigment of the Corpus luteum has been found identical with carrotene such as is present in carrots and leaves, and closely allied to lycopin, the colouring matter of tomatoes. Carrotene has been shown by an earlier investigator to form the yellow colouring matter of wheaten flour. The two classes of pigments are separated by shaking with a mixture of alcohol and light petroleum. The liquid forms two layers, the upper one of petroleum ether containing the carrotene and the lower alcoholic layer containing the xanthophyll.

High Prices for Rare Orchids.—At the recent sale of duplicate plants from the orchid collection formed at The Shrubbery, Oxford, by F. Menteith Ogilvie, Esq., one hundred and sixty lots realised about £1,200. Brasso-cattleya Cliftoni magnificum realised £210; Miltonia vexillaria Memoria E. D. Owen, £126; Cattleya Trianæ The Premier, £37 16s.; C. T. Grand Monarch, £110; Odontoglossum Ossulstoni Shrubbery var., £37 16s.; O. crispum Magnum Bonum, £39 18s.; and O. Pescatorei Duchess of Westminster, £42.

The Hardy Plant Year Book for 1913, the official publication of the National Hardy Plant Society, is the second issue of its kind, and a distinct improvement upon the first. It contains a list of members, prize-winners at the exhibition held in the Royal Horticultural Hall in June last, report and financial statement for the past year, rules, and a model schedule of classes for hardy plants and flowers. Besides all this information there are numerous articles, the chief of which are "New Plants of 1912," by Mr. W. Irving; "New Plants from China," by Mr. E. Horton; "Saxatile Violas," by Mr. W. H. Paine; "The Possibilities of a Rock Garden of Small Dimensions," by Mr. Reginald A. Malby; "Notes on the Perennial Aster," by Mr. Ernest Ballard; and "English Names of Hardy Plants," by Mr. S. Arnott. All these are of great interest, and are freely illustrated. In addition, there is a brief report of the Conference

held at Shrewsbury last August, with the text of Mr. T. W. Sanders' address, entitled "Are Flower Shows Advancing Hardy Plant Culture as They Might or Ought to Do?" On the occasion of the Conference a large number of species and varieties of veronicas were shown, and as many of these seemed to be so confused a trial was suggested, and the work was kindly undertaken by Mr. F. Bouskell, Market Bosworth, Nuneaton, the chairman of the society. Members are being asked to send plants of either species or varieties so that this trial may be as complete as possible, and so enable the special committee to reduce the nomenclature to its proper position. Any information concerning veronicas will be gratefully received by Mr. A. J. Macself, hon. secretary, 52, Beechfield Road, Finsbury Park, London, N.

Royal Gardeners' Orphan Fund.—The twenty-fifth annual dinner in aid of this valuable charity will take place at the Hotel Cecil, Strand, London, on Thursday, May 15, under the presidency of Colonel the Right Hon. Mark Lockwood, C.V.O., M.P. As the total amount annually disbursed in allowances to the orphans closely approaches £1,900, the committee make an urgent appeal for substantial financial assistance on this occasion.

Dr. W. Botting Hemsley, F.R.S.—We learn with pleasure that the University of Aberdeen has conferred upon Mr. W. Botting Hemsley, F.R.S., formerly Keeper of the Herbarium at Kew, the Honorary Degree of LL.D. The graduation ceremony took place recently, but, unfortunately, Mr. Hemsley was unable to attend in person to receive his degree.

Royal Botanic Gardens, Edinburgh.—An informal meeting was recently held at the Royal Botanic Gardens for the purpose of considering the advisability of forming a guild of past and present members of the staff. The temporary committee elected to take the necessary initial steps will be very glad if all the old members of the staff would communicate their addresses either to Mr. W. H. Morland, the secretary pro tem., or Mr. H. Harrow, so that the list may be made as complete as possible. A circular containing the proposed rules will then be forwarded them.

Regulations for the Growth of Tobacco.—The Commissioners of Customs and Excise have issued the regulations under which tobacco may be grown for nicotine extraction. According to the first regulation, a person who desires to obtain the authority of the Commissioners of Customs and Excise to grow tobacco within the United Kingdom solely for the purpose of obtaining an extract therefrom to be used without payment of duty for the manufacture of insecticides for horticultural purposes, must furnish on a form of application to be obtained by him from the proper officer a statement of the variety or varieties of tobacco to be grown and of the process of extraction to be used by him, and such further particulars as may by the form be required, and must return the form duly filled up and signed by him to the officer. The application may be made at the same time as the application for a licence to grow tobacco, or by a person who has already obtained such a licence, and the authority when granted shall be in force only during the currency of the licence. The second regulation is to the effect that a person to whom an authority has been granted, must in connection with this authority, grow only such variety or varieties of tobacco as may be approved by the Commissioners, and all tobacco so grown by him must be used solely for the purpose of an extract being obtained therefrom. Under the third regulation no alteration of the process of extraction, as described in the form of application, shall be made without the sanction of the Commissioners. The remaining regulations are not less important, and those who contemplate the cultivation of tobacco for the purpose of making a nicotine extract should obtain a copy and become well acquainted with them before commencing cultural operations.

Orchid Show at Birmingham.—The annual exhibition of orchids and early summer flowers under the auspices of the Birmingham Botanical and Horticultural Society will be held at the Botanical Gardens on Wednesday, July 11. Honorary exhibits of flowers, fruits, and vegetables will be welcomed. Particulars may be obtained from Mr. T. Humphreys, Botanical Gardens.

Experimental Orchard for South Australia.—Considerable progress is being made with the experimental work conducted at the orchard established by the Horticultural Department of the South Australian Government, situated in the Coromandel Valley, Mount Lofty. The orchard has an area of 52 acres, and it has already been the means of rendering great assistance to the fruit growers in the colony. The plantations include 1,400 varieties of apples, 181 of figs, 800 of pears, 320 of peaches, 80 of nectarines, 360 of plums, 40 of olives, and 152 of strawberries, besides raspberries, currants, etc.

NEW PLANTS AND FLOWERS.

CARNATION MRS. WILFRED GOTT.

One of the most beautiful of new carnations, and one that must be classed as a perpetual malmaison. It is evidently the result of crossing a malmaison with a perpetual variety. Of strong habit, it bears large and noble flowers of purest white, and with a most delicious fragrance. A.M., R.H.S., April 1. Messrs. Wm. Cutbush and Son, Highgate.

BRASSO-CATTLEYA HEATONENSIS CANARY.

This beautiful hybrid was represented by a grand plant carrying six large blooms. The parents were Brassavola Digbyana and Cattleya Hardyana, and the colour of the flowers is quite pale yellow, with deeper yellow in the lip, where there is also some exquisite pink shading. The fringing of the large lip is very beautiful. F.C.C., R.H.S., April 1. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

CARNATION MRS. WILFRED GOTT.
Flowers pure white. A.M., R.H.S., April 1. Messrs. W. Cutbush and Son, Highgate.

CATTLEYA INTERTEXTA JULIETTE.

A beautiful pure white cattleya with soft yellow markings in the throat of the lip. C. Mossiæ alba and C. Warneri alba were the parents. A.M., R.H.S., April 1. Mons. Firmin Lambeau, Brussels.

CYMBIDIUM HUMBLOTI.

A strong-growing tropical species from Madagascar, its stout, broad leaves like those of some angræcums, its spikes suggesting a branched cymbidium, and its flowers, by their appearance and colour,

reminding everyone of Cœlogyne pandurata. The spike exhibited was about four feet long, and had six branches, each bearing about a score of flowers and buds. The colour is pale apple-green with blackish markings upon the greenish yellow lip. Mr. C. Curtis, the old Veitchian collector, remembers finding this species in Madagascar forty years ago, but he was unable to bring home live specimens then. F.C.C., R.H.S., April 1. Messrs. Charlesworth and Co., Haywards Heath.

CYPRIPEDIUM ROUNDHEAD.

The florists could find little or no fault with this hybrid between C. nitens and C. Earl of Tankerville. The flower has a rounded, shapely appearance; the broad dorsal sepal is white, with greenish yellow base and centre, and over the coloured portion dark red-purple spots are freely strewn. Both petals and lip are greenish-yellow, heavily shaded with bright red-brown. F.C.C., R.H.S., April 1. Lieut.-Colonel Sir George Holford.

LÆLIO-CATTLEYA DOMINIANA SOUTHFIELD VAR.

A splendid flower, of large size, and with a very fine ruby-purple lip. The sepals and petals are light rose-purple on a creamy-white ground, but the bright colouring is somewhat streaky. F.C.C., R.H.S., April 1. W. Waters Butler, Esq., Southfield, Edgbaston, Birmingham.

ODONTIODA KEIGHLEYENSIS IGNITA.

In this neat form of the hybrid between Cochlioda Noezliana and Odontoglossum cirrhosum, the flowers are larger and more shapely than in the original cross, and of a brilliant crimson-scarlet colour. A.M., R.H.S., April 1. Messrs. J. and A. McBean, Cooksbridge, Sussex.

ODONTIODA COOKSONIÆ RALLI'S VAR.

A charming variety with rounded flowers borne on a strong spike. The colour, crimson-scarlet, is very vivid, and distinctly enhanced by the white apex to the lid. A.M., R.H.S., April 1. Pantia Ralli, Esq. (gardener, Mr. Hunt), Ashtead Park, Leatherhead.

ODONTOGLOSSUM EXIMIUM WARNHAM COURT VAR.

A very beautiful odontoglossum derived from the fine O. crispum Luciana and a good form of O. ardentissimum. As shown in our illustration on p. 235, the flowers are of fine size and excellent shape. The blush ground colouring is heavily blotched over with rich crimson-purple; the apex of the lip is white. F.C.C., R.H.S., April 1. C. J. Lucas, Esq. (gardener, Mr. Duncan), Warnham Court, Horsham.

DOUGLASIA LÆVIGATA.

A pretty, densely tufted alpine plant from the Oregon mountains of North America. It closely resembles an Androsace. The tiny leaves are surmounted by small umbels of purple-rose flowers, each a little less than half an inch across, and with a rose-red eye. A.M., R.H.S., April 1. Mr. Maurice Prichard, Christchurch.

NARCISSUS WHITE EMPEROR.

This is not a white counterpart of the well-known Emperor daffodil, but is a rounder and more refined flower. It has broad, rounded, cream-white perianth segments, and a wide trumpet, prettily frilled at the mouth. White Emperor was raised by the Rev. G. H. Engleheart, who stated that it was of pure Ajax parentage; the majority of those who saw the flower also agreed that this was a trumpet variety, but some sticklers for rule used finely graduated measures, and proved to their own satisfaction that it was a Giant Leedsi variety. Three members of the Daffodil Committee were deputed to classify the variety, but could not agree, though we understand the majority favoured the trumpet rather than the Leedsi classification. Anyhow, it is a beautiful daffodil, and goes to show how crossing and recrossing the various varieties and types is breaking down even recent definitions; consequently new varieties will have to be arbitrarily placed in one or other of the nine groups into which daffodils are at present classified. A.M., R.H.S., April 1. Messrs. Cartwright and Goodwin, Kidderminster. Also shown by Mr. C. Bourne, Bletchley, who, with Messrs. Cartwright and Goodwin, hold the stock.

PRIMULA VISCOSA OTHELLO.

Scarcely so robust as the foregoing, but extremely free-flowering, this variety should find great favour in the rock garden. It bears many-flowered trusses of deep rich purple colouring. A.M., R.H.S., April 1. Mr. James Douglas, Great Bookham.

PRIMULA VISCOSA JEAN DOUGLAS.

This very fine primula is really a hybrid between P. viscosa and the alpine auricula named Innocence. Of robust growth, the plant exhibited bore three fine trusses of bloom, the large one containing over a score of flowers. The colouring is bright purplish-rose, with white eye. There was some doubt expressed as to the identity of this plant, and it was at first considered identical with P. viscosa Mrs. Berkeley, but subsequently it was found distinct, and to have been raised at Great Bookham. A.M., R.H.S., April 1. Mr. Jas. Douglas, Great Bookham, Surrey.

SENECIO STENOCEPHALUS.

A strong growing species from China and Japan, and one that promises to be of value for the semi-wild garden, and possibly for the waterside. It has handsome, bold, reniforme leaves with deeply toothed margins, and these often measure 16 inches across. The golden ray florets are usually five in number, and the flowers are placed closely together in sturdy racemes a foot or more in length. Bot. Mag., t. 8472.

ROSA SERTATA.

This very handsome Chinese rose has very small leaflets, and large rose or rose-purple flowers, and makes a graceful shrub 3ft. to 5ft. high. The blooms measure upwards of two inches across, and have a dense central cluster of golden stamens. It flowers about mid-June, and its blooms are followed by deep red fruits, so that in autumn its bright hips, glaucous stems, and dainty leaves render it a very attractive shrub. Bot. Mag., t. 8473.

AMORPHOPHALLUS CORRUGATUS.

Though the genus of Amorphophallus is of little value in gardens, it has the distinction of containing the largest flower known—using the word flower in its widest sense, of course—this being produced by the huge A. titanum. A. corrugatus is from Siam, and has a green-purple shaded, white-mottled spathe. The spadix has a dull yellow apex, with a cluster of rosy male flowers below, and a group of dull purple female flowers at the base. Bot. Mag., t. 8475.

ASTER PURDOMI.

Collected by Mr. W. Purdom, in Northern China, when travelling for Messrs. J. Veitch and Sons. A. Purdomi promises to be a very useful and beautiful garden plant, and one especially suitable for the rock garden. It is a small-growing plant, and has hairy leaves about 1½in. long. The flowers are 2½in. across, pale violet, with yellow centre, carried erect and solitary on stems about six inches high. Bot. Mag., t. 8476.

CŒLOGYNE CRISTATA.

This old and popular garden plant is one of the most beautiful of orchids, and its semi-pendulous spikes of white flowers, with golden-crested lip, are well known for their decorative value. This old species has the honour of a double-page illustration in the Bot. Mag., t. 8477, and the history of its introduction in 1837 is given.

OVER-GROWN CELERY SEEDLINGS.

Cultivators will have raised their batches of celery plants at this time, and experienced growers will not make the mistake of subjecting the resultant seedlings to a too high temperature.

Very frequently one sees the plants drawn up, and then the best results cannot be secured. I do not object to placing the seed pan on the surface of a mild hotbed, nor, indeed, to plunging it to the rim, but I would prefer not to plunge the pan. The mistake is made when the pan is plunged in a very strong heat, the top darkened, and the young seedlings kept in this position for a week or longer. Under these conditions the young plants are much drawn and greatly weakened.

Celery should be raised under cooler conditions, and sown very thinly, being fully exposed to the light from the moment the seedlings break through the soil. Very often a lot of seeds are sown in a small pot or pan, ten seedlings growing in the space where one should be. The cultivator gets all the plants he needs from one corner, and the remainder—ninety per cent.—are thrown away. How much better it would be if a few seeds were scattered evenly all over the surface of the soil. The seedlings would be strong from the very first, and continue to gain strength.

When transplanted all the seedlings selected should be of the same size, so that the matured plants will be so when lifted for use; as, unlike cabbages and similar crops, the matured specimens cannot be gathered here and there. I have found it advisable to grow celery plants on a cool base throughout, after the first transplanting, as many plants grown on hotbeds have "bolted," or been pithy and hollow-stemmed. G. B.

QUERCUS DENSIFLORA.

This is one of the rarest evergreen oaks cultivated in the British Isles, and few examples are known to exist, although two good-sized trees may be seen in the Kew collection. A native of Western North America, it is found from the southern parts of Oregon to Southern California, where, under the most favourable circumstances, it attains a height of one hundred and fifty feet, with a trunk up to four feet in diameter, sometimes clear of branches for half its height. The oblong leaves are from two to five inches long, and between one and two inches wide. When young they are whitish on both surfaces, by reason of the presence of numerous short, felty, grey hairs. With age much of this pubescence disappears from the upper side, but it remains beneath throughout the life of the leaf. The leaf margins are rather prominently toothed, and the veining is very conspicuous. The acorns take two years to mature.

Jepson, in his "Silva of California," says that its bark produces the best tannage known for heavy leathers, and that the trees are usually barked standing. After they are barked they often live two years, and mature a heavy crop of acorns the second year. Sometimes, however, the trees continue to live for an indefinite period after barking. So popular is the bark said to be that 100,000 trees are often sacrificed in a single year for the bark alone. The wood is used, to some extent, for house and wagon building. In California the common names of Tan Oak and Squaw Oak are applied to the tree. W. D.

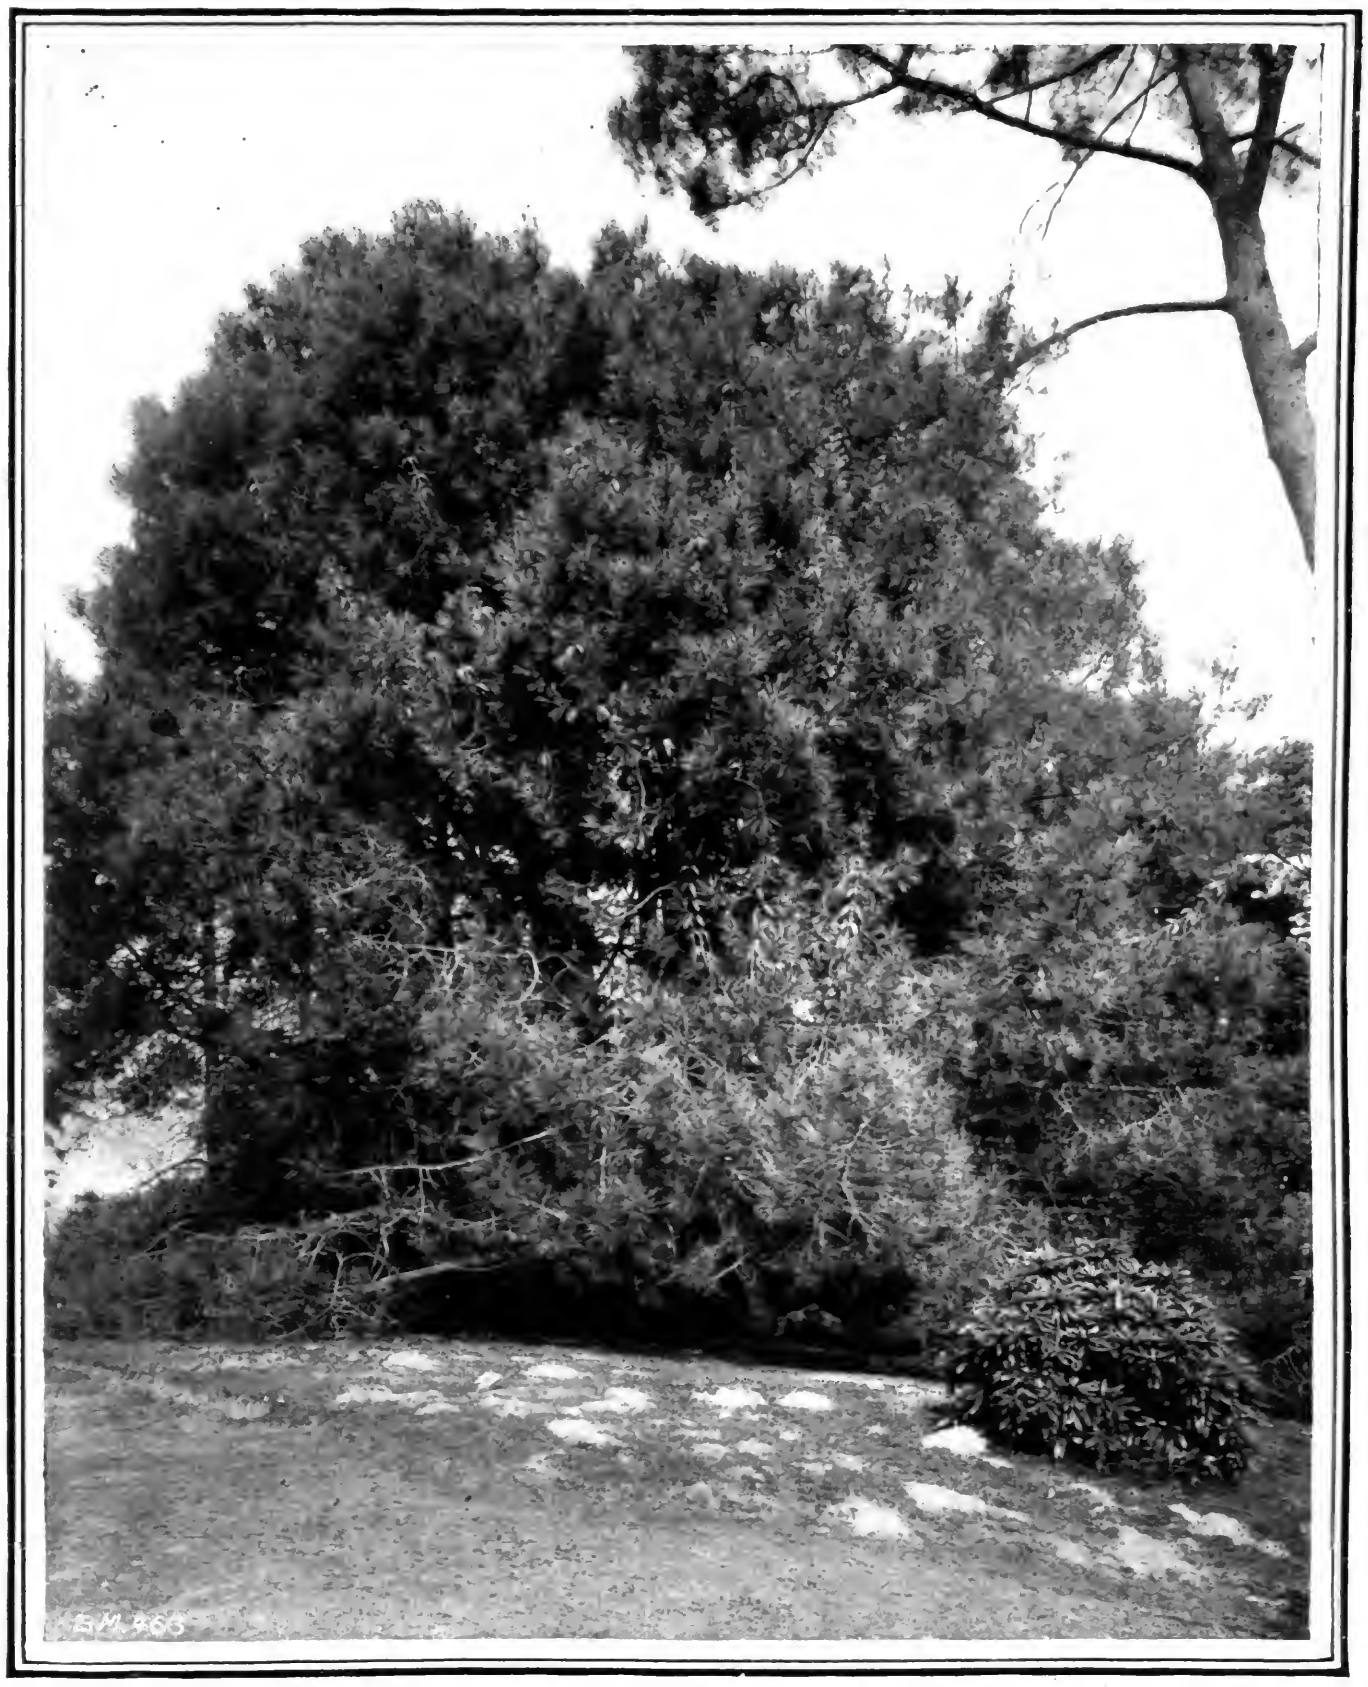
FINE CONIFERS AT BURY HILL.

To those who are acquainted with the southern parts of Surrey it is well known that the interesting and quiet town of Dorking has for its setting some of the most delightful scenery to be found, not only in the county but in this fair England of ours. There may be scenery of greater boldness, but there is none possessing greater beauty, and, whether rambling through the wide-spreading vales or climbing the lofty hills that form so prominent a feature of the landscape, it is not difficult to understand why those who appreciate the many charms of the country should in their thousands annually visit the district. It can also be readily understood why so many stately mansions and important gardens are to be met with around Dorking, more especially by those who appreciate invigorating air as well as great natural pictures of surpassing beauty.

Great gardens abound, and prominent among them are the gardens of Bury Hill, the seat of Robert Barclay, Esq., which, with the mansion, extend over a considerable area of the spur of the range of hills that skirt the southern side of Dorking and continue for some distance in a westerly direction. The mansion and gardens are a mile or more beyond the western boundaries of the town, and, as one enters the park gates and walks or drives along the road that skirts the northern side of the hill on which the one has been built and the other formed, a foretaste is obtained of the distinguishing characteristics of the grounds. The horticultural features of Bury Hill are numerous and varied, but the one that stands out prominently among those deserving of special attention is that formed by the coniferous trees, of which the collection is extensive, and the majority of the specimens quite unique.

These trees were, for the most part, planted in the first half of the nineteenth century, and, as both Mr. Barclay's father and grandfather were keenly interested in conifers, all the finer kinds that were then available were included in the selection made. Others of more recent introduction have since been added, and the collection is thoroughly representative, and as by far the greater proportion of the specimens have assumed noble proportions, they afford object-lessons of much value to planters. It is not difficult for those who have the time to visit a number of large gardens to find a considerable number of trees that have been growing in their present position from twenty to thirty years ; but to find nearly all the leading kinds with an age of sixty or more years elsewhere in any one garden would not be a very light task. In another respect the Bury Hill collection differs materially from those which usually come under notice in visiting great gardens in which conifers have been largely planted. Taking full advantage of the natural features of the ground the trees were so arranged that now they have attained their full development they present much the appearance of a natural woodland, or of a portion of one of the slopes of the smaller mountains in California or some other part of the world on which several species are growing in association.

To make this point more clear it is necessary to state here that the pleasure-grounds extend over a large area of the southern side of the hill, at the foot of which the mansion stands, and that to the south of this there are great breadths of lawn with specimen trees of various kinds and beds and borders for hardy and other plants. There are specimen conifers on the lawn, but the trees forming the collection

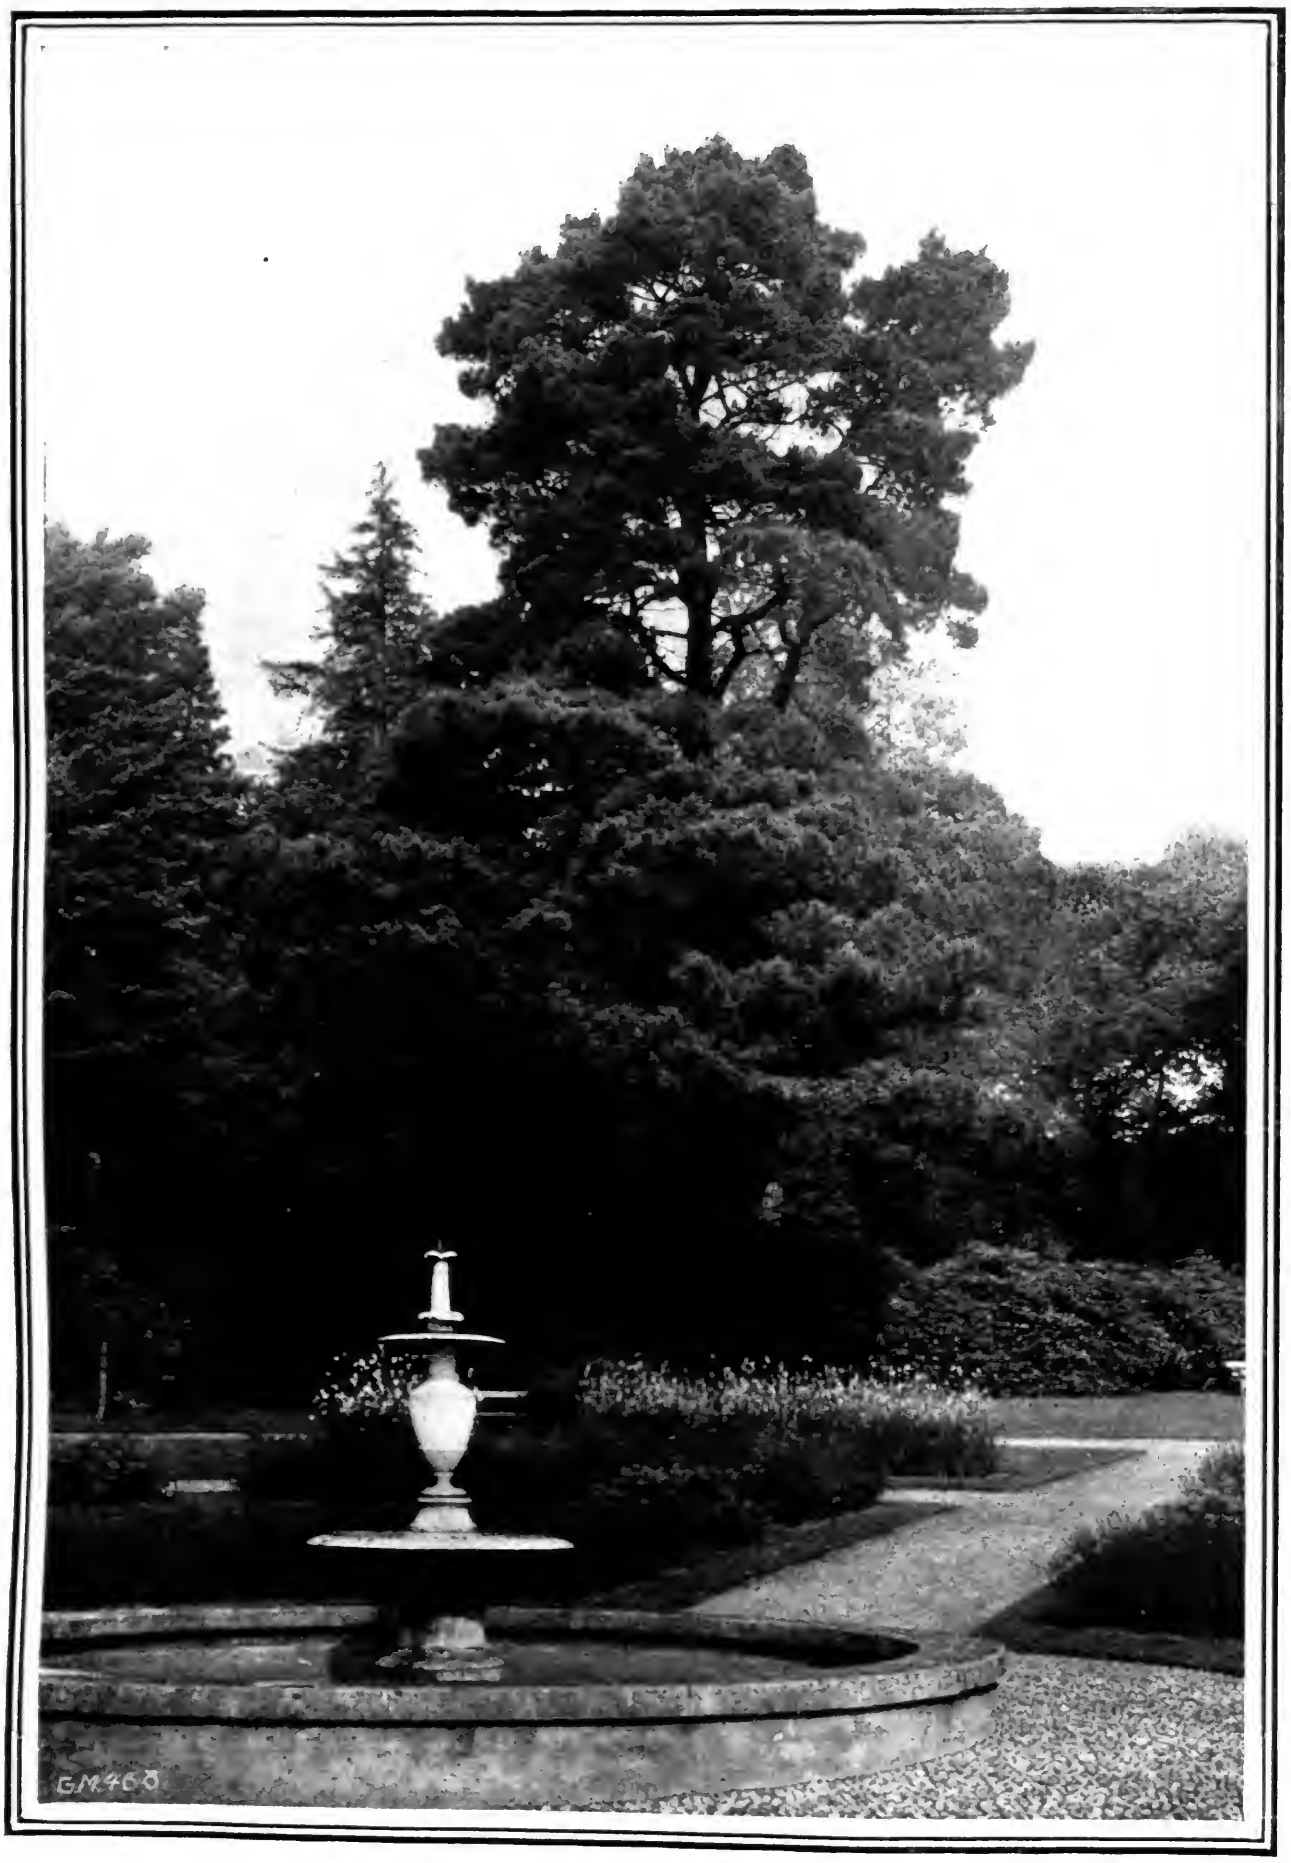


PINUS TUBERCULATA AT BURY HILL.

are mostly growing on the slopes and ridge of the hill, and form a magnificent background to the mansion, which is of grey stone. Since the conifers were given their present position rhododendrons have been freely planted among them, and these now form a remarkably fine undergrowth, and while their rich green leafage is always restful to the eye, they constitute a distinct and immensely attractive feature in their season of flowering. Originally Himalayan species, choice hybrids, and varieties of ponticum were planted, but within recent years Mr. Barclay has had much replanting done for the purpose of giving more space for the development of the choicer kinds, and Mr. Graysmark, the able gardener, would appear to have been remarkably successful in carrying out his employer's wishes. The ponticums have been greatly reduced, with the result that not only is the general effect much improved, but the dimensions which the finer kinds have attained can be readily seen. Of Rhododendron arboreum and its varieties and other Himalayan kinds, there are many specimens of large size, and annually they bloom with great freedom. Growing in the more open spaces are big breadths of daffodils bearing myriads of their golden flowers, and adding appreciably to the pleasure of a leisurely walk among the trees.

The pines are the most strongly represented in the collection, and one of the finest of all the specimens is that of the handsome Monteroy Pine (Pinus insignis), which is growing on the north-eastern margin of the flower garden, and is herewith illustrated. It will be readily seen that a specimen which, as in this instance, has attained its full development under favourable conditions, is remarkably handsome, the effect produced being greatly enhanced by the rich green colouring of the leaves. The tree is 99ft. high, and has a girth of 15ft. at 5ft. from the base of the trunk. Of a widely different character to the foregoing is the fine specimen of P. tuberculata that is growing within a few

paces of the observatory that occupies a prominent position on the ridge. This species is remarkable more for its interest than its beauty, and was introduced by Hartweg in 1847 when engaged in North America as a collector for the Royal Horticultural Society. Dr. Sargent describes it in his "Silvia of North America" as "a tree usually about 20ft. high," in its native forests, and the few specimens in this country are of quite moderate dimensions. At Bury Hill the conditions appear to have been favourable to its development, for the



THE MONTEROY PINE (PINUS INSIGNIS)
In the gardens of Bury Hill, Dorking.

specimen, which divides at a few feet above the ground level, and has several leaders, has attained a height of 60ft. and a spread of 65ft. It has the distinctive characteristic of producing its cones on both the branches and trunk, many of them remaining on the tree twenty-five or more years, some becoming embedded in the bark. The leaves are light greyish-green, a colour that is not particularly attractive.

Remarkably handsome are the specimens of P. excelsa, which is a native of the Himalaya, and has a rather wide range. It is noble in aspect, free in growth, and succeeds in all parts of the United Kingdom. It is distinguished by the spread of its branches, and should therefore be allowed ample room. The trees at Bury Hill were planted in 1846, and all are in a high state of development, the largest having a height of 94ft. There is a good specimen of the comparatively rare P. Coulteri, which was discovered in 1832 on the Santa Lucia by Dr. Coulter, and seeds were subsequently collected by David Douglas, and sent to the Royal Horticultural Society. The tree has a height of 50ft., and a roundish head. If not one of the most ornamental pines, it is not without its attractions, and is well worthy of inclusion in a collection. The New Jersey, or American Scrub Pine (P. inops), is a tree of moderate growth, not specially attractive, but of interest, and in this country the height of fully-developed specimens range from 30ft. to 40ft. That at Bury Hill is 38ft. high.

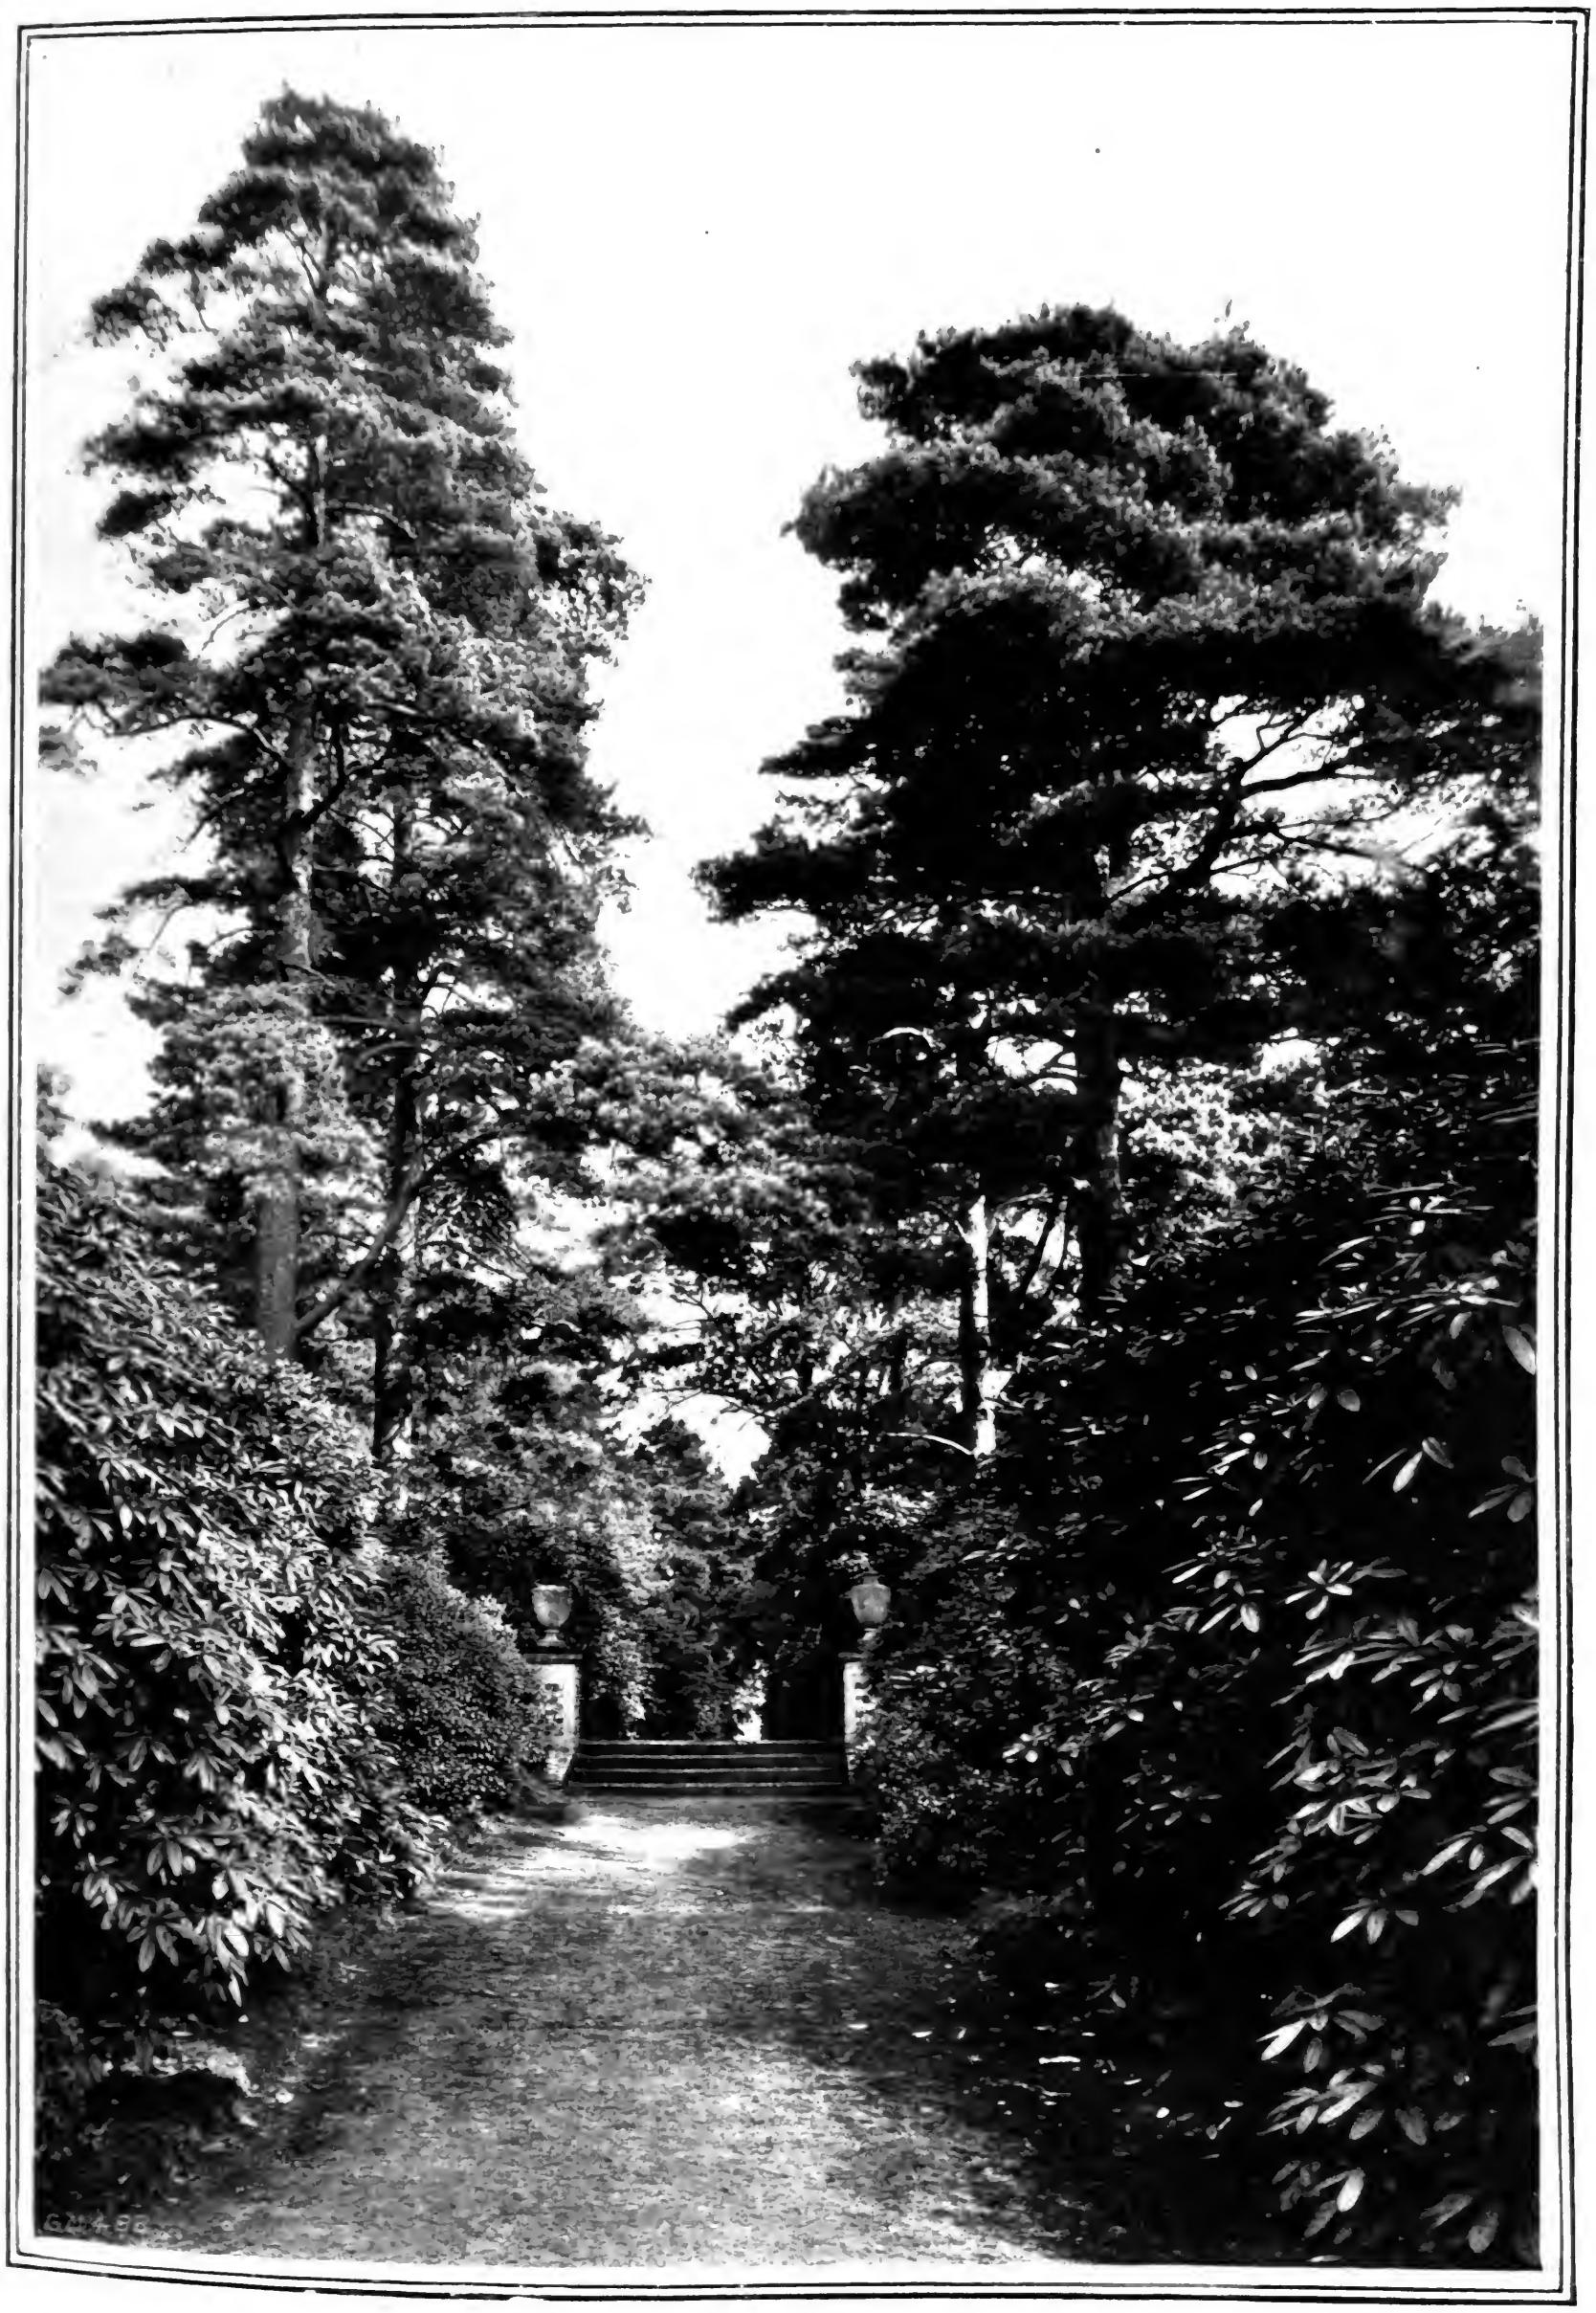
The handsome and tall-growing Sugar Pine (P. Lambertiana) is represented in the collection by a very fine specimen which was planted in 1845, and has now a height of 79ft. It has a columnar habit, a bright green colour, and is distinctly handsome, and bears large cones from which resin exudes somewhat freely. The attractions and interest of the collection is greatly enhanced by the splendidly developed specimens of the Corsican Pine (P. Laricio) and its varieties. Of the specific form the most noteworthy of the specimens is that planted in 1815 and now having a height of 105ft. P. Laricio calabrica is 90ft. high, and is splendidly furnished to a comparatively low level. Well known for its handsome appearance in a comparatively young state, the Corsican Pine becomes highly picturesque as it approaches full development, and standing singly or arranged in groups, old trees produce a fine effect in park scenery, as does the variety mentioned and some other of the forms. Other pines that combine a vigorous growth and strong constitution with a handsome appearance are the Weymouth Pine (P. Strobus) and the Scots Pine (P. sylvestric), of which there are numerous finely-developed specimens. The largest specimen of the Weymouth Pine has a height of 98ft., which is considerably above the average in this country, and among the trees of the Scots Pine, which were planted quite early in the nineteenth century, are some that have a height of 80ft. The picturesque appearance of venerable specimens is well shown in the illustration of the rhododendron walk, but there are a few trees growing lower down the slope that are rather larger.

One of the most noteworthy trees of the lesser-known conifers at Bury Hill is the distinct and handsome P. Montezumæ, a Mexican species discovered at the beginning of the last century, contiguous to the City of Mexico, by Humboldt and Bopland, and introduced to this country in 1839 by Hartweg. Plants were subsequently distributed by the Royal Horticultural Society, and it is probable that this specimen is one of these. The tree is 40ft. high, which is quite exceptional, for the species has some difficulty in contending with the adverse influences incidental to the British climate. The leaves are 9in. or so in length, and bluish-green, and in the young state the tree has a broad pyramidal outline.

Of the Cluster Pine (P. Pinaster) and the Stone Pine (P. Pinea), there are several specimens, and the tallest of the trees of the first-named has a height of 84ft., while the largest of the latter is 80ft. high. The variety of P. Pinaster known as Hamiltoni is represented by a handsome tree of large growth, which was planted in 1846, and is 80ft. high. This form differs from the type in having broader and shorter leaves. The Stone Pine is remarkable for its large round head and deeply furrowed bark, and, as evidenced by the Bury Hill specimen, is one of the most picturesque of the conifers when it has attained a large size. Another pine of noble proportions that is finely represented in the collection is P. ponderosa, of which there is a specimen growing in the heavy soil near the lake. This has a height of 91ft., and occupying an open position, the trunk is well furnished with branches throughout the greater part of its length.

Turning to the choice firs, it is found that the most noteworthy of the specimens of the bold and handsome Douglas's Fir (Abies Douglasi) are the two growing in association with the large example of Cedrus Deodara on the margin of the flower garden not far distant from the specimen of Pinus insignis herewith illustrated. These have a wide spread of branches, and the tallest of the two has a height of

21ft. and a girth of 14ft., 5ft. from the ground. These were planted in 1832, and the growth has therefore been at the rate of nearly 17in. annually. On the ridge some distance from these specimens is the fine specimen of the Weeping Douglas Fir (A. Douglasi pendula) that was illustrated in the GARDENERS' MAGAZINE of January 11, 1913. This latter was planted in 1849, has a height of 70ft., and is one of the most graceful of coniferous trees. A. grandis and A. magnifica, two of the most beautiful of the large-growing kinds are splendidly represented, the finest of the specimens of the former being 96ft. high, and that of the latter 64ft. Of great beauty also is A. bracteata, which possesses much interest for the distinct form of its cones, and the sparing manner in which they are produced. The specimen is 56ft. in height and is perfect in development, the spread of the lower branches being 36ft., and it produced cones for the first time last year, a fact to which reference was made in these pages in the issue of February 22. Noteworthy also is the specimen of the variety of A. concolor known as Lowianum, which has a height of 72ft., and is remarkable for its elegant outline. The chief points of difference between this variety and the specific form are the greater length of the leaves and their darker shade of green.



A BEAUTIFUL WALK IN THE BURY HILL GARDENS.

With noble specimens of the Scots Pine (Pinus sylvestris) and Rhododendrons.

The Common Silver Fir (A. pectinata), which has much value for park planting is evidently at home in these beautiful gardens, for the largest specimen has a height of 123ft., and is in all other respects well developed. Of the handsome Greek Fir (Abies cephalonica) there are three fine specimens, the largest having a height of 91ft., and a girth of 7wt. 6in. at 5ft. from the base.

As so well-known the species of Picea comprise some of the most beautiful of the firs that have not found a place in British gardens, and the majority of the finer kinds that have been long in cultivation are admirably represented. The specimens of the free growing and elegant White Spruce (Picea alba) include one with a height of 109ft., and of the noble Sitka Spruce (P. sitchensis, syn. P. Menziesi) there is a specimen of special interest. The tree has attained a height of 113ft., and was removed from another part of the grounds to its present position in 1856, when it was 40ft. high. The Indian spruce (P. Morinda), which has a wide range in the Himalaya, and was introduced to this country in 1818, is one of the most elegant of the firs, and the finely developed specimen at Bury Hill shows how charming is the effect it is capable of producing in the pleasure grounds. The specimen is 76ft. high and well-furnished with growth to within a short distance of the ground.

Among other trees that must have a brief reference made to them are the three specimens of the Deodar (Cedrus Deodara) which formed part of the first six trees that were introduced to this country. Four of the six were planted at Bury Hill in 1832, and one of these was blown down a few years since. Of the three that remain one has a height of 102ft., and another of 98ft. Cupressus Lawsonianum is found rising to a height of 65ft., C. pisifera squarrosa to 38ft., Thuja gigantea to 86ft., Taxodium sempervirens to 98ft., and Wellingtonia gigantea to 89ft., and all well-proportioned, the last-named being especially so. Very fine also is the handsome Moreton Bay Pine (Araucaria Cunninghami), which flourishes in the Bury Hill gardens, as does the well-known A. imbricata, of which there are several exceptionally fine specimens.

Many more interesting trees might with advantage have been mentioned, and the reference to a considerable number of those included in these notes been considerably amplified, but the limitation of space has rendered this impracticable.

George Gordon.

THE DEODAR (CEDRUS DEODARA) AND DOUGLAS FIR (ABIES DOUGLASI) AT BURY HILL.

NOTES FROM KEW.

Erlangea tomentosa.

As befits a plant that made its first public appearance in this country at Kew, Erlangea tomentosa plays a conspicuous part in the embellishment of the greenhouse there. Not only is it now flowering with great freedom, but for some months it has contributed to the floral display. Apart from the fact that its flowering season extends over six months or so of the dullest period of the year, this Erlangea possesses the merit of being of very easy propagation and culture. It is now too well known to need any detailed description; therefore it will suffice to say that it forms a freely-branched plant of a partially woody nature, and bears a considerable resemblance both in growth and flower to some of the eupatoriums. In the erlangea, however, the flowers are of a kind of lavender tint.

Eupatorium trapezoideum.

Where a large, bold-growing species of eupatorium is desired for a good-sized structure, this species, of which there is a group in the greenhouse, can be well recommended for the purpose. It forms quite a bold, freely-branched plant 4ft. to 5ft. in height, the clusters of white flowers being borne in great profusion.

Oxalis floribunda.

This oxalis forms a very pleasing basket plant in the greenhouse, possessing, as it does, the merit of distinctness from the subjects commonly employed for the purpose. When suspended, the rich green trifoliate leaves, supported by long pedicils, form a very pleasing feature; and, in addition to this, the bright rose-coloured blossoms are freely borne. There is a white-flowered variety (alba), but it is scarcer than the type. A native of Chili, Oxalis floribunda has been known in this country for nearly a century.

Richardia Rehmanni.

When first introduced, about twenty years ago, great interest was centred in this richardia—firstly, on account of the shape of its lanceolate leaves; and, secondly, with regard to the colour of the flowers, which was described as pink. Those first introduced, however, showed but little colour, and that more of a muddy hue than pink. In the T-range there is now flowering the richest-coloured form that I have seen, the spathe being of a deep purplish-rose, with a blotch of purple-crimson at the base. In this form it is certainly a very distinct and fairly ornamental species. K.

Rhododendron Edgeworthi.

The blossoms of this Himalayan species are large and pure white, except for a blotch of yellow in the upper part of the interior of the flower. A notable feature of R. Edgeworthi is the delicious fragrance of the flowers, a feature which is transmitted in a greater or lesser extent to all its progeny, for it has been largely employed for hybridising.—W.

ORNAMENTAL GRASSES.

There are many positions in a garden where ornamental grasses may be used with telling effect, but nowhere do they yield more charming harmonies or greater contrasts than when grouped close to water. Plants that make no claim to attract attention by conspicuous beauty must of necessity call for different treatment than if the effect desired was a floral one, and the commonest error that planters of ornamental grasses fall into is vain repetition, which not only weakens a composition, but produces a sense of irritation.

A typical instance of the misuse of grasses in garden ornamentation is found in the case of the pampas grass. This is one of the few grasses in which the inflorescence attains to conspicuous beauty, and is strong enough in this respect to immediately arrest the eye; consequently, when it appears at frequent intervals it causes distraction, and instead of giving emphasis to the garden scheme, its oft repeated presence becomes a source of weakness, from which the whole scheme suffers. Another grass that frequently suffers in a similar way is Arundo donax, the great reed of the Mediterranean regions. The form known as A. d. macrophylla glauca is a handsome object in any water-garden scene, where it introduces a unique effect. The topmost, undeveloped leaf is erect, like a lance-point, while the fully-expanded leaves suggest pennons, and the softest breeze is able to set all in motion. The glaucous blue-grey colour of the leaves is an outstanding feature of this fine plant. Arundo conspicua is quite distinct from the last named, being more in the way of a small pampas grass, but it flowers in July, whereas the true pampas does not flower until the end of September.

Miscanthus (Eulalias) are useful grasses, frequently used among herbaceous perennials in borders, where they are quite appropriate in large gardens, but lack sufficient merit where the area treated is small. I have used them as a foil to Lilium croceum and varieties of L. umbellatum, the miscanthus widely planted, with liliums between them, and if top-dressed with rich manure each season, the lilies do not suffer from the greedy roots of their companions.

It is this aspect that should have the greatest attention directed to it when introducing grasses, for we are falling into the tendency of regarding and even model. ing our flower borders on the principle of the exhibition table, producing huge banks of colour, that approximate to, if they do not actually reproduce, the gaudiness of an Oriental scheme. This principle, while good in its own place, is quite foreign to the water garden, which depends on more subtle influences for its charm, where light and shade, and the form of leaf contrasts directly with that of the flower, and where every bay and promontory should present a different aspect, inviting comment and sustaining interest from start to finish. Viewed in this manner, grasses occur as foils or monotones that indirectly give emphasis to the higher colours, while in themselves they impart grace and lightness to the scene.

Some grasses, like Carex pendula, C. riparia, and C. japonica; Scirpus zebrinus, Glyceria spectabilis variegata, Juncus effusus striata aurea, J. lacustris, and J. spiralis, Typha angustifolia, and T. minima, will grow either submerged in shallow water or in ground kept continually moist. Arundo donax and its varieties are partial to much moisture in the growing season, but enjoy drier conditions in winter. This applies also to the varieties of miscanthus, and Phalaris elegantissima, and all the bamboos. Planted in ordinary garden soil, in a sunny aspect, Elymus glauca is a singularly beautiful grass; its foliage is intensely blue-grey, while it fills up quickly, and soon forms a thicket some 18 to 24 inches high. Stipa pinnata is also a pretty grass for similar positions.

The silver and golden forms of Dactylis glomerata, and Festuca glauca with its blue-green, thread-like foliage, are three of the dwarfest grasses, frequently employed in bedding arrangements, and valuable at all times for edging or to form a carpet for taller subjects. THOMAS SMITH.

Coombe Court Gardens.

STRAWBERRIES.

The fruiting season of any crop, the harvest of our labours, should be the most enjoyable time in its cultivation. No matter, however, what has been accomplished to advance the crop at any other period in the year, all will be largely wasted if there is neglect during the time the crop is reaching maturity; therefore no details should be neglected.

Of all fruit crops there is, perhaps, no other that suffers so readily if neglected during its fruiting season as does the strawberry. The lack of needful nourishment, either in the form of proper fertilisers, or moisture, quickly has a serious detrimental effect upon it, and, moreover, it is so liable, especially when matured, to be destroyed by birds, mice, slugs, and insect pests, and so easily damaged by wet weather, that usually it is by no means an easy matter to secure a good crop.

With reference to feeding I have found farmyard liquid manure a most valuable fertiliser. There is, however, some difficulty experienced in making use of this owing to the uncertainty of its strength. We once made a mistake in this way when using drainage from stables, which resulted in our main crop being injured. Of this liquid there may be given during the season three thorough applications, viz., one when the plants commence to grow, a second when they commence to blossom, and a third soon after the fruit has set. Soot is another valuable manure for applying at this season of the year, and apart from its manurial properties, it acts as a deterrent to slugs. Nitrate of soda is also invaluable as a manure which can be most conveniently and effectively made use of after being finely crushed. Because of its moisture-retaining properties, this is especially beneficial when used upon light soils, and particularly so in dry seasons. It must be kept from the centre of the plants and the young leaves, otherwise it may cause injury.

Strawberries at no time must be allowed to suffer from want of moisture at their roots, and where necessary efficient supplies of water must be given.

Mulching is another necessary proceeding that renders at least two very useful services: that of keeping the fruit clean and preventing rapid evaporation. Clean straw is the best material to use, although in cases where the fruit is staked, and kept from coming into contact with it, carefully-prepared stable litter will answer. In arranging any kind of mulching material, it should be made level over the whole of the soil surface, and carefully placed under the leaves and close up to the base of the plant. A suitable time to attend to this detail is immediately before the blossoms open.

Fruit grown for dessert or for exhibition should be both thinned and staked, and these operations should be done as soon as sufficient fruit has commenced to swell to furnish the crop required. As a rule, the earliest blossoms to unfold (crown blossoms) produce the finest fruits, and when strawberries are required for exhibition all others should be removed at the time of thinning. It greatly depends upon situation, if it is, or is not, essential to protect the blossoms from frost; in all low-lying places, at any rate, it is advisable to take this precaution. Here it is absolutely necessary to do so, for if it was disregarded the earliest blossoms, and therefore the best of the fruit, would invariably be sacrificed. Strips of tiffany answer well as protectors, and they can be readily placed over, or removed from the rows of plants, while if they are taken care of, they last for many years in good condition.

Repaired herring or pilchard netting gives satisfactory protection from birds, and a good way of making use of the nets, once the fruit commences to colour, is to secure them to a framework formed of stakes having about three feet of their length out of the ground, and placed in rows over the plantations, with lines of galvanised wire secured across their tops, the margin of the netting being pegged to the ground. In connection with this we have for exhibition purposes prolonged the keeping powers of the fruit by placing tiffany, as soon as the fruit has finished colouring, over enclosures of this kind, the sides of the enclosures being left uncovered to allow a current of air to freely circulate. By this means, the fruit is protected from powerful sunshine and heavy rain, and thus kept for a lengthened time perfect in appearance, though the best flavour is not preserved to the same degree. On one occasion, when we exhibited a collection of strawberries at Holland Park, during an unusually wet season, one of my gardening friends asked if our fruit had been grown under glass, and, upon being informed that it was gathered from outdoor plants, replied: "Well, then, you must have been favoured with much better weather than the rest of us have been," but this, nevertheless, was not the case, but the fruit had been efficiently protected in the manner described.

Of depredators other than birds, mice are perhaps the most destructive, but by perseverance with figure four or other traps, baited with cheese, they may be soon got rid of, and the better way of doing this is to clear the quarters before the fruit becomes tempting.

Slugs, as has been intimated, may be checked by dressings of soot or nitrate of of soda, though where the fruit is staked—a profitable practice to adopt in the case of choice dessert crops—they do but comparatively little damage. Millepedes are harmless to staked fruits, and in other cases they may be trapped by pieces of beetroot, or mangel, placed beneath the leaves. Ants are best dealt with by finding and destroying the colony. T. COOMBER.

Hendre Gardens.

LARGE ANNUAL ASTERS.

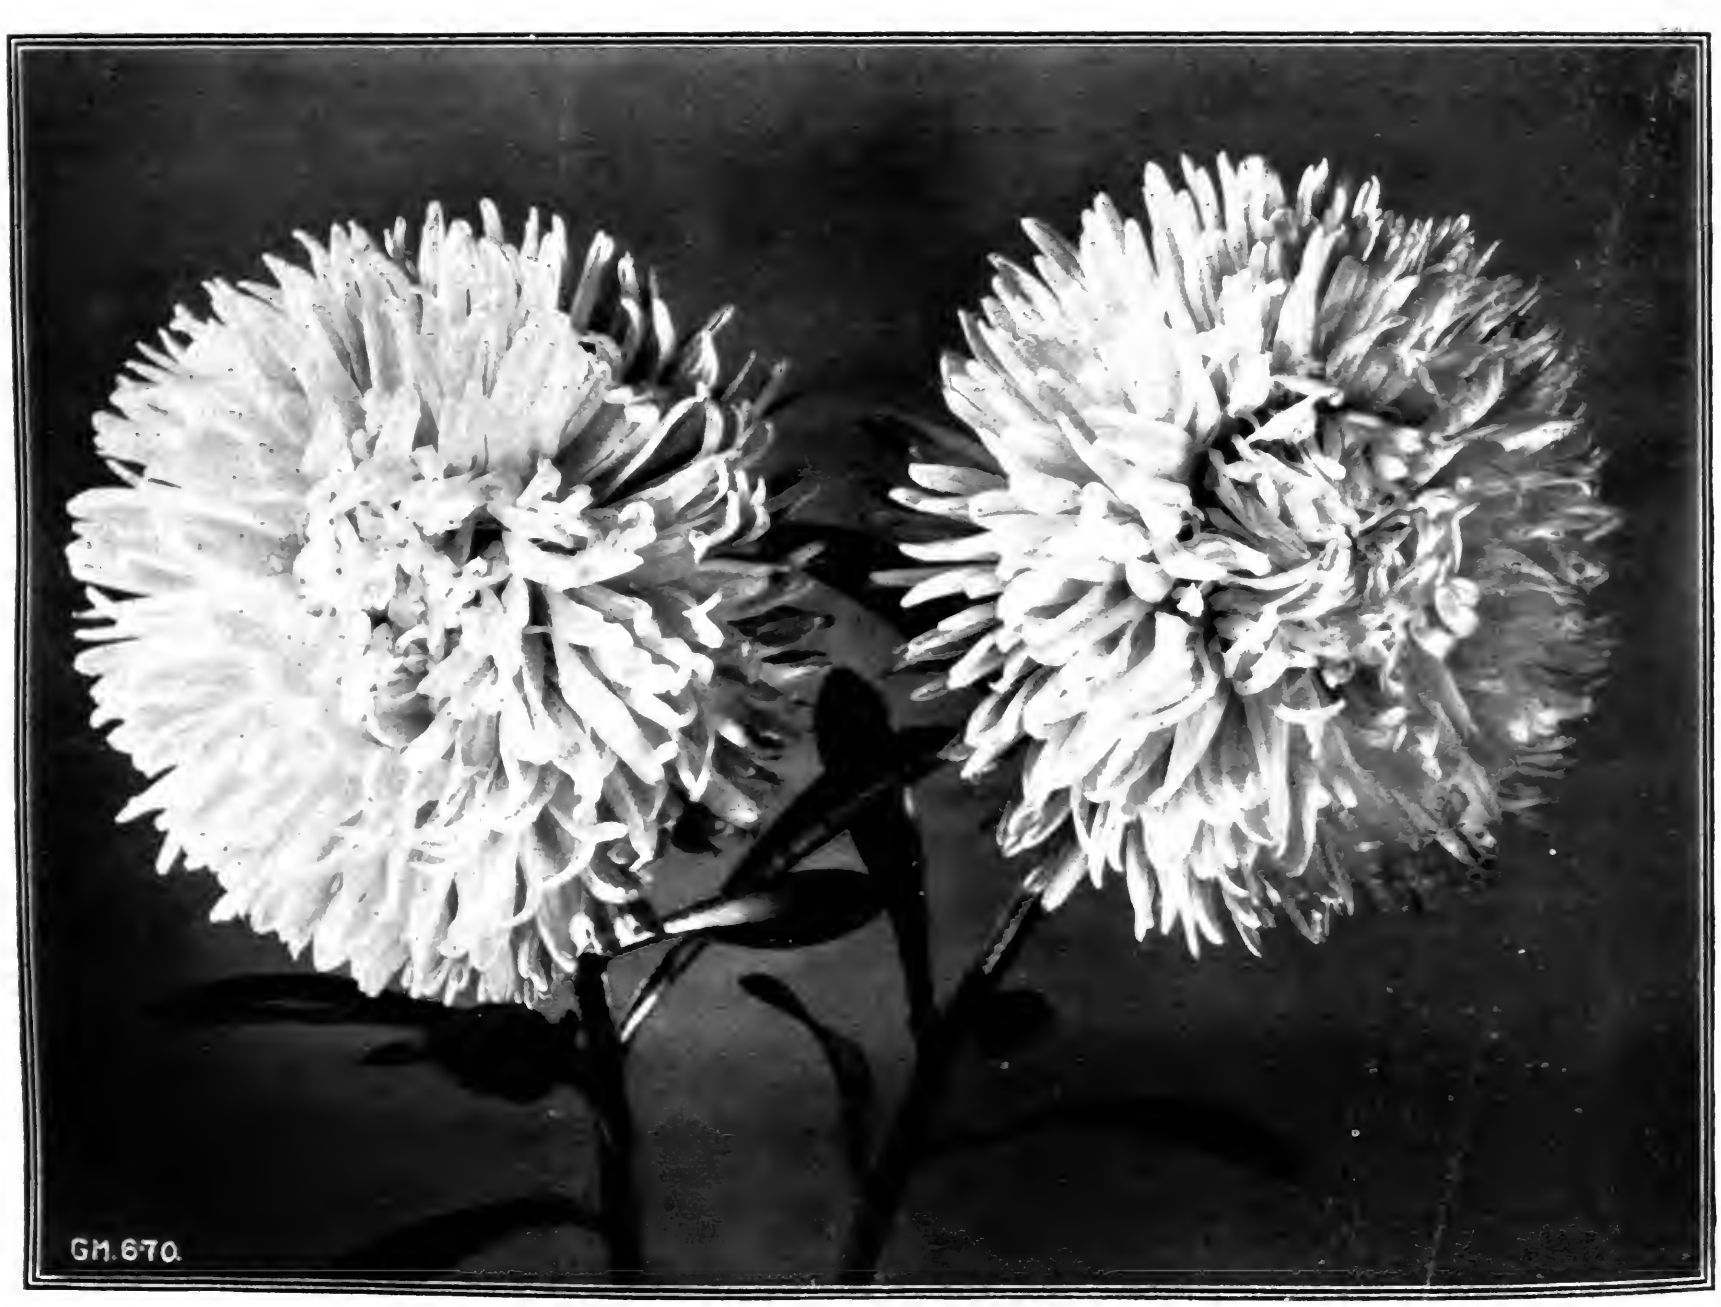
It may appear strange to admit it, but the fact remains that in these times I sow no annual flower seeds beyond sweet peas and asters. A garden of annuals is a delight, but those who, like myself, want to make gardening easy, shirk the trouble, be it ever so little, that many annuals incur. By growing bulbs, herbaceous plants, and roses, I obtain practically all the flowers I desire, and so I worry not about seeds other than those named.

The aster gives the maximum of pleasure with no great amount of trouble, and the flowers are very much below the stocks produced in the United States, where climatic conditions are much more favourable to the highest development of this flower.

It may surprise some to learn that certain American varieties of asters reach nearly four feet in height, and the special market blooms have stems up to three feet in length, while prices as high as four shillings per dozen have been made. This is a very different return from what is usually secured here, where rates rarely exceed six shillings per dozen bunches, or about one gross of blooms. Although I have never been able to equal the American sizes, I have often cut flowers five to six and a-half inches across on stems twenty to twenty-four inches long, and the object I have always in mind when growing flowers is their value for cutting. So far as asters are concerned it is quite a simple matter to get big blooms and long stems if one handles the right types. Moreover, one needs no greenhouse; not even a frame.

I raise my asters, as do most of the Americans, by sowing in the open ground about the first of May. Drills half an inch deep are made between the sweet pea rows, and newspaper is laid over the rows until the seedlings are through. If at all crowded, some of them are pulled out, and later, when carrying a few leaves, and about one and a-half inches tall, they are transplanted to where they are to flower. I always grow one row of asters between each row of sweet peas; the rest of the plants are put where there is room. If there is a spot in the kitchen garden available asters are planted, and these come in useful for lifting when in flower.

Sowing in heat and pricking out is waste of time, and, as often as not, it means drawn, weakly plants, which receive a check when planted out. Asters, if once checked, never make good plants, and by transplanting straight from the seed bed one avoids the second shift. Further, open ground sowing means no trouble from "damping off." When planting out, never set deeply, and remove any foliage that touches the soil. Deep planting, and allowing foliage to decay, invariably results in wholesale dying off, often just when the plants are running to bud.



ASTER PEERLESS PINK.

Flowers blush pink, and when well grown about 5in. in diameter.

by cultivating the giant, mid-season, and late types, one can almost dispense with the early chrysanthemums. Early asters do not appeal to me, neither do the dwarf types. These I quietly ignore, as they are only suitable for edges or bedding, and my garden prohibits their use. Ultra early forms are scarcely required when so many other flowers are available, and so I survey the efforts of those who aim to get asters in June without the least enthusiasm.

The asters I have favoured for some years past are the American forms. Experience has proved that there are no finer seeds than American-grown, and, taken collectively, the American asters are superior to the average European, particularly if one can secure the specially selected stocks such as are grown by the American market men. Asters are very largely grown in this country for the markets, but the quantity and quality of

The best soil for asters is a heavy loam, and plenty of rotten manure should be used, but on no account use fresh manure in the spring. Failing the right sort of manure, use dried blood, or fish manure, with a fair addition of superphosphate. Potash is most essential, and the sulphate form is perhaps the best; use no nitrates whatever, or the plants will run to leaf, and easily become a prey to disease. Lime liberally before planting, and dust lime between the plants several times during the season. Keep the hoe everlastingly on the move, and give plenty of water in dry weather.

Mulching is useful, but I never mulch. Some of the big American growers water their fields by the Skinner overhead system, and along the Pacific Coast water is essential, for there is little or no rain throughout the summer.

The tall varieties of asters require

staking, as the heavy flowers are apt to be damaged or torn about by wind and rain in the autumn.

The following varieties are my favourites, but there are several newer American types I have not yet tried, including the Upright Branching, which are erect in growth, instead of spreading, as are the average branching types. Peerless Pink, a fine giant blush-pink, averages thirty inches tall with blooms five inches across and quite two and a-half inches deep. Marvel Late Branching can be had in azure blue, white, purple, and rose-pink. These are September-October flowering, all very large, and in form similar to Vick's Branching. Another Branching, i.e., Crimson King, Shell Pink, and Deep Rose, form a very fine strain of late bloomers, but there are several other colours. The Giant White and Giant Pink are magnificent forms of the Comet type, and easily lead this section, with the exception of the German Hohenzollern, which is not to be surpassed by any other white Comet variety, but American-grown seed is better than European; at least, that is my experience.

Electric, another German variety, might be called a quilled Comet; the petals are narrow, and very stiff. It is pure white, and comes six inches across, but is rather flat. Mikado Pink, or Rochester, is a gem, with delicate lavender-pink flowers. It is one of the finest asters of the Comet type ever raised, and a great favourite in America. It was raised by Vick, and it is the official flower of the city of Rochester, New York. Violet King, a deep purple of the branching type, has rather narrow petals, but is a very full flower; a real masterpiece, and a great rival of the chrysanthemum, which shows nothing in this colour.

Anyone growing such asters as these can reckon on flowers from four to seven inches across, without the removal of flower buds other than those that may appear on the individual flower stems. The branching types average eight to twelve flowers each. No pinching is necessary with these asters, and, so far as my experience goes, the flowers do not gain much in size if the plants are kept to three or four stems.

T. A. Weston.

DIMORPHOTHECA AURANTIACA.

This is one of the most showy of annuals, and useful both for conservatory decoration and for planting out in the flower borders. The colour of the flowers are a rich orange, with a black blotch at the base of each petal. It requires a position fully exposed to the sun, for if planted in the shade the flowers will only partly open, and the beauty of the plant is not then seen to advantage. From one to two dozen plants should be grown in a group, and then a most brilliant effect is produced; in fact, the colour is quite dazzling. The seeds should be sown in pans, filled with light, sandy soil, and placed in a warm house to germinate. In March or April, when the seedlings are large enough to handle, they should be transplanted into boxes, and allowed to remain in the house until they recover from the disturbance. After becoming fairly established, cold frame treatment is most suitable. The plants may be potted when necessary, grown close for a time, and gradually hardened off.

E. C. P.

ASTER ELECTRIC.
Flowers pure white and about 6in. in diameter.

AMONG THE ALPINE FLOWERS.

". . . Mezereon, too,
Though leafless, well-attir'd, and thick beset
With blushing wreaths, investing every spray." —*Cowper.*

Though the Mezereon has been long in bloom, yet we find it a good companion to the lowlier flowers of the rock garden. If kept well pruned, it associates well with the alpine flowers of the late March and early April time, and we welcome the continuance of its blossoms on their wreathed branches. In various shades of purple or white it is very attractive, and is one of the old-fashioned shrubs we cannot dispense with even at the present day. It has rivals among its kindred, but we cannot safely banish it without losing some of the charm of the garden in spring.

European Dog's-tooth Violets.

So, also, may one say of the old-fashioned dog's-tooth violets, varieties of Erythronium dens-canis, which are in full bloom as this is written. We feel that they are less graceful, and that they have less subtle beauty than their American kinsfolk; but they come earlier, and give us great pleasure by their shapely, reflexed beauty, and their beautifully spotted or marbled leaves. They are so beautiful, with their flowers of crimson, purple, pink, or white, that in the rock garden they cannot fail to please us. They are so cheap, too, these European dog's-tooth violets, even in the case of such named varieties as Humboldt, Franz Hals, Rouge Trappense, and all the varieties of E. dens-canis major, that we can afford to plant them in groups instead of in ones or twos. It seems almost absurd to suggest their inclusion now in face of the exquisite American species, but it is folly to refuse to avail ourselves of good things, even if they are comparatively common and inexpensive. Let the varieties be of the best; give them a fairly good soil on a level part of the rockery, and they will assuredly give a "reaping time of joy."

Saxifraga Burseriana Gloria.

This is, at present, the best procurable form of the charming Burser's saxifrage, and a very beautiful thing it is with its spiny foliage, a picture in itself to the student of leaf-beauty, and its lovely snow-white flowers on wonderfully tall stems for a Burseriana saxifrage. It, like its sister flowers, appears to do best in a moraine or semi-moraine bed, and the writer knows of a very fine plant, which is a joy with its exquisite flowers in a small corner, where it luxuriates with some of its allies in a mixture of loam, sand, lime rubbish broken very small, and sand. For its greater comfort and that of its cousins a sash is placed over the bed in winter to preserve it from the wet of the district. Here it is a dream of loveliness. In this compost, with some fresh soil of the same kind mixed among its rosettes after the flowering is over, and well worked in, it flourishes rarely and well. I believe that it has a rival, but that rival has not yet made its appearance in the market. When "magna" comes forward, it may be that we shall look upon Gloria with compassion as the monarch dethroned: but meantime we do full homage to the beauty of this queen of the Burserianas.

Potentilla Valderia.

Long years ago—among my first Alpine purchases, indeed—I secured a little white-flowered carpeting potentilla with silvery leaves. I can recollect its arrival as one of the "gratis" plants we sometimes see enclosed in a fair order for Alpine flowers; but, to one's discomfiture, it came without a name, and simply under the vague title of "Potentilla sp.," rather an unsatisfactory designation for anyone. Not in the first ranks of Alpines, this small cinquefoil has remained with me for many long years, and is still one of the plants which I should not care to be without. It was some years before I could learn its name, but it is more appreciated now, when we know it by its true title, and not by that elusive and tantalising one of "Potentilla sp.," the resort of the unknowing, and one which is most annoying to the keen alpinist. It is pleasant to notice that it is now appreciated in high quarters, and to observe it more frequently in gardens than before. It comes very early—March had not begun when its first white flowers opened on the silvery carpet this season. It is very hardy; it appears absolutely indifferent to sun or shade; stands drought well, though happier with plenty of moisture at the roots; and is, therefore, a plant for the many. Let me emphasise, however, that it is not a potentilla which we would include among the six choicest of its race. Yet it is one of the earliest, one of the most reliable, and, with its silvery look and its white flowers, is not to be looked upon with disrespect.

Mazus pumilio.

Many of us will follow with special interest the record of the behaviour of the lovely Mazus rugosus, so well described and illustrated in the Gardeners' Magazine the other day, and its beauty will tempt many of us to embark upon its cultivation. It appears a fitting time to recall the notice of the alpinist to its more familiar ally, Mazus pumilio, a plant which has been for a good many years in cultivation, but which is not too frequently met with now. It is, indeed, less plentiful than it was when I first obtained it, some thirty years ago, fired by the drawing in "Wooster's Alpine Plants" to own this lovely little flower. It was impossible for a lover of Alpines to see the coloured plate without seeking to make the real plant his very own. So it was bought and grown, only to find, however, that, like most other flowers of its class, it has a way of its own, and that it is a little difficult to keep in a wet winter. It is a dainty creeping plant, with small wrinkled leaves and very beautiful flowers of purple and white, on short stems. For a sheltered nook in sandy soil, Mazus pumilio is a little beauty, loving, however, the protection of a glass in wet winters, and then giving its lovely little flowers happily in June and July.

Other Flowers.

Of many other flowers one would fain speak, were it not for the rigid limitations of space. Aubrietias, now begun to bloom, give bright colouring: arabis is in sheets of snowy-white; primulas easy, and primulas choice and difficult; saxifrages in many forms; old-fashioned lungworts; dainty rock tulips; bulbs of other kinds not a few, with a galaxy of lesser beauties, adorn the garden. Over all there is yet the golden and silvern glory of the narcissus in its many forms. Charming in the grass, the smaller narcissi are no less lovely in the rock garden. S. Arnott.

GARDEN DAHLIAS.

April is possibly the most important month in connection with the preparation of dahlia plants intended to give a display of bloom during the summer and autumn. If the best results are to be obtained the plants must now receive the most assiduous attention, but with work pressing on all sides this is sometimes a difficult matter, and yet it must be remembered that a check in any form may have serious consequences, and few subjects resent neglect more than dahlias. Take care that the plants do not suffer from want of water, and potting must be attended to before there is any danger of the plants becoming rootbound, but, undoubtedly, what will cause the most serious check of all, if it makes it appearance, is red spider, and once the plants are badly attacked they rarely do much good after.

Proper attention at all times, in the way of watering, potting, spraying, and ventilation, is undoubtedly the best preventive. Greenfly, which sometimes appears on the young growths, may easily be kept at bay by fumigation, or dusting with tobacco powder.

All plants, whether grown from cuttings, pot roots, or old tubers, should now be growing well, and ready for their final potting about the third week in April. This allows a month to five weeks before the transfer to flowering quarters, and in this time they will make fine plants, all well rooted. The size of the pot, of course, entirely depends on the requirements of the plant, and varieties vary in habit and vigour. The earliest rooted cuttings, which should have received several pottings, will take eight-inch pots. Pot roots should have at least seven-inch pots, and old tubers generally require pots seven inches and upwards in diameter.

It must not be thought, however, that good plants are impossible in pots of lesser size. Thousands of plants will be sent out this month, and early in May, in small pots, by dahlia specialists, and these, if well rooted, as they probably will be, should be immediately transferred to larger pots. The mistake is often made of keeping them in the small pots as received until planting time, and a check is the result, from which they are slow to recover, and their period of blooming is considerably shortened. The great value of fine, well-rooted plants is that they are so much better prepared to face the possibility of warm weather in June, and grow right away, whereas it is a great strain on small plants, and the season is advanced before they commence to grow freely.

A good compost for final potting consists of three parts fibrous loam, one of flaky leaf-soil, and one of old mortar and brick rubble, the latter passed through a quarter-inch mesh sieve. After potting the plants should be kept close, slightly shaded from strong sun, and occasionally sprayed. A house with slight heat is preferable, but a cold frame, with every advantage taken to conserve sun heat, and well covered at night with mats, will answer very well.

After a week or ten days commence to gradually harden the plants, eventually exposing them fully. All plants should be in cold frames by the first week in May.

GARDEN GLADIOLI.

Lovers of the gladiolus have been provided with a new interest now that seed is offered that will give plants to blossom in five to six months' time. This strain, too, gives large blooming spikes of innumerable colours. All that is necessary is to sow in glass-covered pans, or singly in small pots, of very sandy compost, keeping these in a cold frame or cool greenhouse, or even in a sunny room window, in March; no bottom heat or forcing on must be attempted as this invariably defeats its object, if not resulting in absolute failure. Some gardeners may prefer to sow out of doors in April, where plants are wanted, as the undisturbed seedlings will bloom well within the five months. The best method of all is to sow in drills along a border, very sparingly, having first introduced a compost of fresh turfy loam, with a sixth part of coarse sand, and a seventh part of hop manure. The last especially suits the constitution of the gladiolus.

Seedlings raised singly in pots, then shifted on, as they require, until they can be turned into the beds or borders in May being more guarded from root disturbance than seedlings raised in pans, will blossom sooner.

Gladioli corms can be planted throughout March, April, and May.

It is not generally recognised that the corms of Gladiolus Lemoinei can safely be left in the ground all winter. These should therefore be employed in lavish quantity for the decoration of shrubbery glades and bank sides and summits, where constant lifting and replanting is not desirable. The colours of the hybrids include numerous shades of yellow, rosy-crimson, mauve, and cream, all blotched effectively on the lower petals. Probably the finest type is Gladiolus Childsi, for the spikes are extraordinarily long, and the blooms of great size, in keeping with the vigorous habit of growth.

The vermilion of Gladiolus Brenchleyensis is well adapted for making a gorgeous note in a landscape, one of the loveliest of Gloucestershire gardens being famous for the great displays of it in borders adjoining a pergola clothed only by cream, white, and yellow roses and mauve clematises. Massed in the borders of a house front, against a white or grey building, it is certain to create autumn splendour that will be welcomed by every passer by.

The early-flowering varieties are now numerous, for in addition to The Bride (white) and Rosy Gem, which used to be the sole representatives, we may plant the peculiarly brilliant Fire King, a combination of pinky-salmon, cerise, and deep scarlet; Prince Albert, a red with white flakes; and Insignis, a crimson marked with purple; while Blushing Bride, a white with carmine blotches, reminds the observer of the popular old-fashioned kind of primulia. This is also one of the very best for gathering, as it lasts even better than others, and all gladioli are long-lived in water.

The soil for gladioli can scarcely be too rich, but it must be deeply dug, and should be well hoed each month, as the growth of leaves and flower stems is infallibly checked if the earth is allowed to form a hard cake on the surface or become a sour mass around the plants. Before hop manure came to the fore many growers found that their gladioli did best in soil liberally mixed with cow manure and old cocoanut-fibre refuse, the latter serving to supply the fibrous dryness that prevented the former from being too damp and heavy. Stable manure suits gladioli well when suitably decayed, and used without straw, as this latter is apt to rot and spoil the corms. The practice of putting half a handful of coarse sharp sand beneath the corms at planting time is an excellent one.

In serried ranks, or ribbon lines, of different colours, the gladiolus gives a glorious show, especially on either side of a grass glade; if the borders and the grass walk are waved the display will, of course, be infinitely more pleasing, or waved lines of the flowers, in straight borders, can be recommended as sure to mitigate much of the undesirable formality.

A large bed of mixed gladioli on a lawn forms a beautiful feature, either with or without a sowing between all the bulbs of the larger Quaking Grass (Briza maxima) or the Mist Grass (Agrostis nebulosa). In a large stretch of open ground can be lavishly planted with the hardy herbaceous Gladiolus Lemoinei and gypsophilas of perennial nature, the appearance in summer and autumn will be of a magnificent floral field, and harvests of blossom will be yielded.

M. H.

NOVEL HERBACEOUS BORDERS.

The mixed herbaceous border is no longer in the fashion, and this not on account of the fickleness of public taste, but because its various demerits have presented themselves forcibly to the growing intelligence of gardeners, both professional and amateur. To arrange a border so that summer blossoms are bound to appear against the dying-down stems and foliage of spring bloomers, to place glorious autumn beauties, such as chrysanthemums, among the (by that season) overgrown clumps of summer-blossoming plants, is to give the kinds their worst chance of attaining perfection and being perfectly appreciated. The best modern method is probably the planting of separate and shorter borders with spring, summer, and autumn flowers, leaving a sufficiently wide belt in front to fill with some plant to give gay colour earlier or later than the others, preferably both, or at least to yield a pretty foliage display.

The summer flowers should be accompanied by crocuses and variegated arabis for a broad edging; for example, the autumn flowers may follow a fine show of pinks, or an invariably excellent scheme is to make the forefront of all the borders into pansy beds, including the bedding pansy, or tufted viola. In rich, well-hoed soil the pansy family will be in bloom from March to December, if given reasonable care; and the plants are easy to tend when massed thus beside gravel or grass walks. Liquid manure and soot water should be given, a mulch of old manure in March and another in August. Shoots must be reduced to prevent both over-flowering and overcrowding, and dead blossoms must not be allowed to form debilitating seed vessels. Under this careful culture the quality and quantity of the bloom harvest is certain to be consistently excellent; the paths will be popular walks during the months of the year solely for the sake of the pansy edgings. Herbaceous plants behind may either exhibit magnificent hues and general attractiveness, or be in the stages of foliage development, or of deterioration, but the garden will possess a fair feature in the same locality.

Another new idea is to keep the perennial varieties by themselves, only carpeting with a contrasting dwarf plant, instead of setting groups at intervals along the whole length. A six-foot space, for example, would be given up to phloxes, the ground around having been earlier a bed of different-coloured pinks; another space would be the home of delphiniums and double daisies, a third of chrysanthemums and dianthuses, a fourth of sunflowers and arabises, a fifth of Oriental poppies and Sedum spectabile, a sixth of hybrid pyrethrums and dwarf campanulas, and so on.

Some gardeners like better to pair the dwarf and the tall perennials so that they blossom together; this enables colour harmonies and contrasts to be arranged, and if the spaces are alternated so that spring is fair in one, summer beautifies the next, autumn is magnificently adorned in the third, and evergreen foliage subjects with such winter bloomers as hypaticas, crocuses, Christmas roses, yellow aconite, and snowdrops are clustered in the fourth, the border as a whole, is delightful to visit at all times. The short stretches that are unornamental are easily forgiven for the sake of the more numerous ones that are gay. For, though we may designate a delphinium a summer flower, a chrysanthemum an autumn one, these plants are but specimens of countless ones which, if generously managed, will blossom over a more prolonged season. Many chrysanthemums begin in July, many delphiniums, after being cut down and manured in June, are, as in this year, observable forming new blossom spikes in September.

The free use of flowering shrubs is now generally adopted in herbaceous borders of fine dimensions. The advantages are undoubted. Not only do many species carry evergreen foliage to set off a foreground of perennial flowers, but berries are produced that stud the branches as with jewels during the most colourless months of the year. Then the shelter thus obtained for low plants enables many delicate species to be cultivated where winds would otherwise wreak devastation, and in scorching sunshine, or spells of drought, the occasionally light shade from the shrub branches is of incalculable benefit.

Borders of separate colours commend themselves to many tastes. They are most suitable in fine pleasure-grounds where all planting of the "spotty" order is out of place. A mass of scarlet, royal blue, azure, yellow, orange, rose, white, cream, mauve, violet, lavender, salmon, maroon, or carmine will be visible right across a belt of parkland from the roadway, or from quite distant windows of the mansion, whereas a mixed herbaceous border will scarcely seem of any tint. Perhaps the better plan is to mingle two harmonious colours, or use cream or white with each gorgeous hue. Scarlet is never so brilliant as when snowy flowers are close by; blue never delights the eye as fully as when cream is its undergrowth or background. Sloping herbaceous borders, against walls, or fences cannot be too highly recommended. The flowers, rising in tiers, one above the other, can be viewed with a freedom never offered by level planting; the height introduces an aspect of majesty, and the blossom trusses of one altitude serviceably hide the bare stems or too prolific leafage of plants slightly taller.

E. G.

Richardia Little Gem. — This pretty little form of the old Richardia (or Calla) æthiopica was twenty years or so ago much sought after. Now, however, it does not seem to be so much thought of, perhaps owing to the fact that it often fails to flower freely. It seems to devote its energies to the production of offsets, and unless these are removed flowers will be but few. Single crowns in four-inch pots will flower well, and the plants are then very pretty.—T.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

MILTONIA VEXILLARIA, in its varied forms, and the different hybrids which have been added to the large-flowered section, are exceedingly useful subjects for decorative and exhibition purposes, and where suitable conditions are provided, there is little difficulty found in their cultivation. A cool intermediate house suits them, but many successful cultivators of M. vexillaria place their plants under the same treatment as the odontoglossums, soon after the plants pass out of flower. Cultivators differ as to their method of treatment. Some advocate repotting in the month of September, soon after the new growths make their appearance, while others prefer to repot early in spring, and in the neighbourhood of London and near other large towns with smoke and fog-laden atmosphere I certainly would advise spring potting. My reason for this is that, after autumn potting, the plants do not resist fogs and damp, dull weather during winter so well as when left without disturbance until the spring, and the plants do not commence rooting as a rule before that period at which the pseudo-bulb commences to form in the advancing growth, about the end of March.

SPRING POTTING. — An advantage obtained by potting in spring is that the new roots at once grow away into the new compost, and so the plants become well established by the time they produce their flowers. The pots used should be sufficiently large to give a reasonable shift, and be filled to two-thirds their depth with crocks or chopped bracken roots. The compost may consist of good fibrous peat, broken oak or beech leaves, and chopped sphagnum moss, in about equal portions, with sufficient sand and broken crocks added to render this porous. The compost should be pressed moderately firm, and a layer of living sphagnum should be spread over the surface. When watering soft water should always be used, for if hard water is applied it will soon destroy the moss, and decay thus set up quickly spreads to the remaining portions of the compost, and causes the whole to become unsuitable for the roots. Thrips are the most dreaded of all insects in the cultivation of miltonias, and regular fumigation, dipping, and spraying must be resorted to to keep these pests in check.

AFTER FLOWERING.—The most critical period in the cultivation of M. vexillaria is usually between the time plants pass out of flower and the production of new growth. At this period they need careful watching because they are liable, with the least excess of moisture, to damp, and the foliage to become disfigured by spot. I have frequently noticed that where the flower spike has not been removed by cutting it off near the base, sufficient moisture accumulates to cause the leaves to rot away, and the decay may quickly spread through the leaves to the pseudo-bulb.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

CELOSIA PLUMOSA.—To obtain good plants bearing well-developed plumes, it is essential that from the seedling to flowering stage they receive no check. Raised in seed pans, as soon as the seedlings can be handled they should be carefully and not too firmly pricked off into thumb pots in a light sandy compost. A cool stage or ash bottom should be provided for them in the intermediate house, not too far from the glass. In bright weather they should be syringed occasionally, the atmosphere and surroundings being kept in a condition conducive to steady growth, and some shading from bright sunshine given. When well rooted they should be potted, and by no means be allowed to become root-bound until in the flowering pot. For this and the final potting a good fibrous loam, with leaf-mould and sufficient sand to keep the whole porous, will be suitable. The worst enemy is red spider, which must be kept down by careful spraying. As the plumes are developed, the plants may be gradually hardened for the flowering house or for the decoration of the dwelling-house.

CROTONS AND DRACÆNAS.—Where rung or notched, and mossed as recommended, these will shortly be ready for removal from the parent plants. This should not be done until the roots are showing freely through the moss, and then great care will be necessary if all the foliage is to be retained. Pot up and at once place in the propagating pit or under handlights in the cucumber or melon pit, shading and spraying frequently until established. Crotons potted in early March are making rapid growth, and will benefit if full advantage is taken of bright sunshine. Ventilate carefully, closing the house early, at the same time damping down and syringing with tepid water. To keep them clean it is advisable to spray the plants monthly with an insecticide, choosing a dull day for the purpose, afterwards syringing with clear water so that the foliage may not be damaged.

GENERAL REMARKS.—Seedlings such as asparagus, smilax, grevilleas, Clerodendron fallax, and others should be potted up as soon as they can be handled and not allowed to become crowded or drawn in the seedling stage. Keep them close and shaded until well established, when, with the exception of C. fallax, they may be removed to a slightly cooler house. Pot up cuttings as they become ready; they will suffer if allowed to remain long in the cutting pots. Saintpaulia ionantha from leaf cuttings are growing nicely, and should be reduced to a single crown when large enough. Keep a sharp look-out for insect pests, spraying or fumigating as may be necessary. When fumigating take care the house and plants are dry or ill effects may follow. With increased sunshine and longer days, temperatures may be proportionately raised, and fire-heat must be used judiciously.—H. Prime, Hatfield House Gardens.

FRUITS UNDER GLASS.

EARLY VINES.—As soon as the grapes in the earliest houses have finished stoning examine the bunches, and remove any small berries which were overlooked in thinning, and otherwise finally trim up the bunches. Examine all ties at this stage, especially on young vines, to see they are not too tight, and keep a sharp look-out in all dry corners for red spider. If this puts in an appearance sponge the leaves carefully at once with warm soapy water; the best preventive is to keep the vines healthy by timely inside mulchings, feeding with warm diluted liquid manure, and syringing if really necessary with clean, soft tepid water. If the vines are moderately cropped and in good health, laterals will continue to grow freely; pinch the stronger, and allow the weakest full freedom.

SUCCESSION HOUSES, where the vines are in various stages, will now require incessant attention, as nothing pays better than performing each operation at the proper time. After disbudding, the shoots push on quickly and soon require stopping, tying, and divesting of all superfluous bunches. The principal care at this stage is to keep the shoots from the glass. Some vines are more tractable than others, but pressure at first should be very slight, and later the shoots may be tied into position without fear of injury. I am not a believer of too restrictive training, but some judgment is necessary, and I like to throw as much strength into the bunches as possible by careful pinching; any vacant spaces can be covered later by tying down the leading laterals.

POT FIGS.—The earliest of these will now need plenty of warm diluted liquid and other stimulants, as pots full of roots require an unfailing supply of rich food to obtain the best results. Plenty of atmospheric moisture is also necessary during the flowering stage and throughout the last swelling as ventilation and fire-heat are increased. Remove all weak growths and pinch gross shoots, as exposure to sun and light are essential to colour and flavour. Allow a night temperature of 65 degrees with a little ventilation, and 75 to 80 degrees on bright days.

SUCCESSION HOUSES.—Trained figs will now require constant attention in thinning out and tying down the shoots. Extension training, where space admits, is the simplest and best for growing good figs, the old branches must be well thinned at the winter pruning, and the trees fed liberally. Where the roots are kept within bounds rich mulchings and liquid feedings are necessary for the surface roots. Shut off fire-heat during the day, and ventilate at 70 degrees, increasing this up to 80 degrees, closing early in the afternoon, together with a free use of the syringe. — F. Jordan, Warter Priory Gardens.

THE FLOWER GARDEN.

WATER LILIES.—The water lily is the most beautiful of all aquatics, and when once established gives little trouble beyond that of keeping them free from weeds and the ravages of water fowl and rats; but when they are grown in ponds somewhat limited in extent, it becomes necessary at times to regulate them, especially in cases where a collection of several varieties is grown, as the stronger habited kinds crowd out the weaker and more delicate ones. If overcrowding is allowed, the graceful setting of the leaves on the water is at once lost, and the number of flowers greatly diminished. In some instances shade from overhanging trees is responsible for much rank growth of foliage at the expense of flowers, so such positions, if possible, should be avoided when establishing new colonies. When treating for overcrowding, thin out by reducing some of the plants. A long-handled Canterbury hoe will be found a most useful implement for this purpose in places where the water cannot be drawn off. The cultivation of nymphæas in artificially constructed ponds or fountain basins is a little more exacting, as usually the boundaries of such structures are composed of cement, thus depriving them of their natural rooting medium—mud. In such instances suitable material has to be applied when planting, and should be either added to or partly renewed each season if the plants are to be kept in a flourishing condition. This is best carried out at this time of the year, which is also suitable for introducing new plants.

BEDDING PLANTS.—The space allotted to summer bedding plants under glass is at this season taxed to its utmost, and constant care and judgment are needed to keep the many different subjects from becoming overcrowded and drawn. Some will be far enough advanced to be removed to temporary structures, where they can be provided with sufficient protection to ward off frost and heavy rains. Zonal and ivy-leaved pelargoniums may be so treated. Specimen plants of fuchsias, heliotropes, swainsonias, etc., should now be well fed to encourage all the growth possible before it becomes necessary to harden them off. Seedling lobelias, pyrethrums, asters, antirrhinums, etc., pricked out in frames should be encouraged by taking advantage of all bright days to damp the plants over just previous to closing the frames early in the afternoon.—T. B. Field, Wych Cross Place Gardens.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Caledonian Horticultural Society.

The spring show of this society was held in the Waverley Market, Edinburgh, on the 9th and 10th inst. The competitive entries did not differ much from last year's, and were above the average. The trade was well represented, and the spacious hall therefore had a very brilliant aspect. Narcissi were scarcely so numerous as on some former occasions in the nurserymen's exhibits, but there was a fine display of bulbous plants generally, and cinerarias were to the fore, and produced a distinct note of colour. Alpine plants, too, were particularly good. The weather was favourable, and there was a good turn out of visitors at the opening ceremony, which was gracefully performed by the Marchioness of Linlithgow. Lord Provost Nicholson occupied the chair, and introduced her Ladyship.

PLANTS.

For the group of orchids, on a space not exceeding 12 feet by 6 feet, variety, quality, and effective arrangement to be considered, for which, along with the first prize of £3 3s., Messrs. Sander and Sons, St. Albans, offer a cup of the value of 25 guineas (to be won thrice before it becomes the property of the competitor), Mr. James Smith, gardener to R. Brooman White, Esq., of Arddarroch, Garelochhead, was the only entrant, and was awarded the first prize. The exhibit consisted of choice odontoglossums and cypripediums.

For four stove or greenhouse plants in flower, Mr. Geo. McKinna, gardener to Sir Robt. Usher, Bart., Norton, Ratho, was first, and Mr. Andrew Findlay, gardener to A. Drybrough, Esq., Gogar Park, Midlothian, second. Mr. McKinna was also first for six plants in bloom (hyacinths and tulips excluded), and Mr. A. McMillan, gardener to the Earl of Home, K.T., Douglas Castle, Lanark, second.

Mr. Kidd, gardener to Lord Elphinstone, Carberry Tower, Musselburgh, was the only entrant for two greenhouse rhododendrons, and was awarded the first prize; and Mr. McKinna was the only entrant and was awarded first prize for four hardy rhododendrons.

For four Azalea indica there were five entries, and Mr. A. McMillan carried off first honours; Mr. Robt. Whannell, gardener to Colonel More Nisbett, The Drum, Midlothian, second; and Mr. McKinna third. Mr. Whannell and Mr. McMillan were the only entrants for two Azalea indica, and were awarded the first and second prizes respectively. For six hardy azaleas Mr. Kidd was first, Mr. McKinna second, and Mr. McMillan third. For four orchids, distinct, Mr. R. McAndie, gardener to Sir A. B. Milne, Bart., Inveresk Gate, Musselburgh, was first; Mr. Albert Jeffs, gardener to R. Hindle, Esq., Edinburgh, was second; and Mr. A. Findlay third. Mr. W. G. Pirie, gardener to C. W. Cowan, Esq., took first prize for a single orchid, Mr. McAndie second, and Mr. Jas. A. Sword, gardener to G. D. Mackay, Esq., Inveralmond, Cramond, third.

There were five entries for three exotic ferns, distinct, and the first, second, and third prizes were to Messrs. J. McNeill, gardener to Major Thorburn, Craigerne, Peebles, A. McMillan, and Thos. Hermiston, gardener to R. A. Robertson, Kirkland, Gogar, respectively. Mr. Hermiston was also first for three adiantums, and Mr. McMillan third, the second prize being withheld. There were three entries for six hardy exotic ferns, but all were disqualified, two on account of tenderness, and one because it included British species. Mr. Wm. Robertson, gardener to Miss Balfour-Melville, Pilrig House, Edinburgh, was first for six dwarf hardy ferns; Mr. Jas. Turnbull, gardener to Alec. Cowan, Esq., Valleyfield, Penicuik, second; and Mr. A. Johnstone, Hay Lodge, Edinburgh, third.

In the class for four foliage plants (exclusive of palms), Mr. John Thorn, gardener to Mrs. Hutchison, of Carlowrie, Kirkliston, was first, Mr. McKinna second, and Mr. A. Knight, gardener to Sir Wilfrid Lawson, Brayton, Carlisle, third. Mr. Thorn was also first for six foliage plants with a very fine lot of crotons and dracænas, the second and third prizes falling to Messrs. Knight and McMillan respectively. Mr. McMillan took first place with a nice lot of plants in the class for six table plants; Mr. McKinna was second; and Mr. P. Hills, gardener to Sir Geo. Bullough, Kinloch Castle, Island of Rhum, third.

For three dracænas Mr. Thorn was first, Mr. McKinna second, and Mr. McMillan third. Mr. Knight took first honours for three crotons, Mr. Thorn being second, and Mr. McMillan third; and in the three classes for palms (four, six, and one), Mr. McMillan took premier place.

There were three entrants for twelve roses in not less than six varieties, and the first prize was awarded to Mr. Thorn; Messrs. W. Galloway (gardener to the Earl of Wemyss, Gosford) and W. Young (gardener to Mrs. Fleming Hamilton, Craighlaw, Kirkcowan) being second and third respectively. There was no entry for H.P. roses.

Mr. Thorn was first for six H.T.'s, and Mr. W. T. Galloway, gardener to Mrs. Dewar, Drylaw House, Midlothian, for two climbing roses.

There were two entrants for four pots of amaryllis, Mr. James Todd, gardener to P. Roy Geddes, Esq., Parkneuk, Colinton, being first, and Mr. J. McNeill, Craigerne, second.

In the classes for pelargoniums, Mr. Wm. Brow, gardener to Mrs. Hog, Gogar Burn, Midlothian, was first for four ivy-leaved and four show, and Mr. R. Whannell was first for four zonal varieties.

Mr. D. McLean, gardener to the Right Hon. R. C. Munro Ferguson, M.P., Raith, Kirkcaldy, was first for four caladiums. Cinerarias made an excellent show. Mr. Brow was first for six large-flowering, Mr. Thorn second, and Mr. Geo. Wilson, gardener to R. S. L. Hardie, Esq., Ashley, Ratho, third. Mr. Robert Stuart, gardener to Viscount Maitland, Thirlestane Castle, Lander, took first place for six plants of stellata forms with well-flowered specimens, Mr. Brow being second, and Mr. G. Wilson third.

Mr. Jas. Turnbull, Valleyfield, was first for Japanese maples. Mr. T. Galloway was first for one deutzia, and Mr. G. McKinna for two deutzias. Mr. McKinna was also first for three Guelder roses and three lilacs; Mr. W. T. Galloway was first for three Viburnum plicatum, and Mr. J. McNeill for two hydrangeas. Mr. Brow was first for three marguerites.

There was a good show in the two classes for astilbes, but dissatisfaction was expressed by several of the exhibitors that the prizes had been awarded to plants which were not in full flower. Mr. McKinna was first and Mr. McLean second in both classes. Mr. James Cossar, gardener to Miss Watt, Spott House, Dunbar, took first place for two dicentras (Dielytras).

Mr. A. Dickson, gardener to M. G. Thorburn, Esq., Glenormiston, Peebles, was first for two pots of mignonette; Mr. R. Whannell for three pots of lily of the valley; Mr. D. McLean for six gloxinias; Mr. J. B. Hamilton, gardener to Miss Paterson, Southfield, Liberton, for six cyclamen; Mr. Wm. Brow for six calceolarias; Mr. D. McLean for six streptocarpus; Mr. R. Whannell for four clarkias; and Mr. Knight for four schizanthus.

In the class for three plants introduced since 1907, Mr. J. Thorn was placed first with the following: Nephrolepis Marshalli, Dracæna Bruanti, and Croton Mrs. T. Sanders. Mr. W. Robertson was second with Primula Bulleyana, P. Unique, and P. malacoides, and Mr. A. McMillan third with Nephrolepis Marshalli, N. Smithi, and Dracæna deremensis Warwicki.

Mr. Wm. Brow was first for six pots of Primula obconica; Mr. A. Dickson, Glenormiston, for six pots of P. Sieboldi; and Mr. Wm. Robertson for six pots of P. japonica. Mr. Dickson was also first for six pots of single Primula vulgaris varieties, and Mr. J. Cossar for six pots of polyanthus. Mr. W. Robertson was the only entrant for six pots of primulas, distinct species, and was awarded the first prize. He showed P. rosea, P. helvetica (seedling No. 1), P. nivalis, P. frondosa, P. Forbesi, and P. mollis. In the auricula classes Mr. W. Robertson was first for six and three pots respectively of alpines, and also for six show varieties, one green edge, one white edge, and one grey edge. Mr. J. Cossar was first for the single self.

The alpine plants were very good. There were two entrants for twenty-four distinct kinds, and the first prize went to Mr. W. G. Pirie, Dalhousie Castle, Mr. A. Dickson, Glenormiston, being a good second. Four entered in the class for six, and Mr. Pirie again took first place. Mr. Turnbull, Valleyfield, was second, and Mr. A. Dickson third.

Mr. J. Wilson, gardener to Sir John Gilmour, of Montrane, was first in both the polyanthus and garden narcissi classes, and he also took first place for six pots of tulips. For six pots of spring bulbs (excluding narcissi and tulips), Mr. A. Dickson, Glenormiston, was the only entrant, and he was awarded first prize. Mr. Wilson was also first for six pots of hyacinths, for which there were only two entries.

GARDEN PLANS COMPETITION.

Prizes for the best garden plans were awarded, in order of mention, to Mr. Hugh G. Oliver, Royal Botanic Gardens, Edinburgh; Mr. J. W. Forsyth, Markyate, Herts; and Mr. Archibald Macey, Godington Gardens, Ashford.

CUT FLOWERS.

In the class for narcissi, twelve bunches in not less than six species or varieties, Mr. W. G. Pirie took first place, the second prize falling to Mr. A. McMillan, who was the only other entrant.

In the rose classes, Mr. Wm. Young, Craighlaw, was first for twenty-four blooms, in not less than eight varieties, and Mr. P. R. Hills, Kinloch Castle, the only other entrant, second. There were three entrants in the twelve-bloom class, in not less than six varieties, Mr. D. Kidd being first, Mr. Young second, and Mr. Hills third. Mr. David Fraser, gardener to Mrs. Callander, Cramond House, Midlothian, was first for twelve blooms of Gloire de Dijon; Mr. John Hood, Helensburgh, for twelve blooms of Maréchal Niel; and Mr. W. G. Price, Dalhousie Castle, first for twelve blooms of any other variety than the above.

Mr. A. Williams, gardener to Lord Strathcden and Campbell, Hartrigge, Jedburgh, was first for three vases of Malmaison carnations, and also for two vases of carnations, exclusive of Malmaisons.

Mr. James Wilson, Montrane, was first for four vases of carnations, exclusive of Malmaisons. Mr. A. Dickson, Glenormiston, was first for six vases of hardy spring flowers.

Mr. D. Kidd was first for three vases of parrot tulips, and Mr. D. McLean for six vases and three vases respectively of any tulips other than parrot varieties.

Mr. G. McKinna was first for twelve trusses of hardy rhododendron flowers, and Mr. D. Kidd for twelve trusses of greenhouse kinds. Mr. D. Mackay, gardener to Chas. Dickson, Esq., Lasswade, was first, and A. Jeffs second for six spikes of orchids.

In the bouquet, etc., classes Mr. A. Holmes, Bellevue Bank, Helensburgh, was first for one white hand bouquet, and one coloured hand bouquet; Mr. McAndie was first for six buttonhole bouquets; and Mr. J. B. Hamilton for one lady's spray.

There were four entries in the decorated dinner table class, but two prizes only were awarded, the first going to Mrs. J. Wilson,

Montrane, and the second to Mr. John Hood, gardener to T. G. Bishop, Esq., Dalmore, Helensburgh.

For three vases of daffodils, arranged for effect, Mr. W. G. Pirie was first, and Mr. A. Dickson was first for three bowls of the same. Mr. James Wilson was first for two vases of lilac.

FRUIT.

Fruit was limited in the schedule to two classes—strawberries and bottled (fresh) fruit. For the former, Mr. G. Anderson, gardener to the Right Hon. A. J. Balfour, M.P., Whittinghame, East Lothian, was first with a very fine dish of Royal Sovereign. Mr. T. McPhail, gardener to Mrs. N. Hamilton Ogilvy, Archerfield, East Lothian, carried off the first prize for six bottles of fruit, for which there were four entries. Mr. J. K. Brown, gardener to J. Oswald, Esq., Dunnikier, Kirkcaldy, being second.

VEGETABLES.

For the collection of vegetables, six distinct kinds, there were two entrants, and Messrs. R. Stuart, Thirlestane, and D. Kidd, Carberry Tower, were placed first and second respectively. Mr. Stewart was also awarded the first prize for a collection of salad plants, Mr. W. F. Staward, gardener to Major-General Sir F. Lloyd, K.C.B., Aston, Salop, being second. Mr. Staward was also first in the single dish classes for two cucumbers, six tomatoes, two bunches of new carrots, six lettuce, and six new turnips. Mr. Cossan was first for fifty pods of French beans, six stalks of rhubarb, and three cabbages. Mr. J. K. Brown was first for twelve forced potatoes; Mr. D. Fraser for 1lb. mushrooms; Mr. Pirie for six heads of seakale; Mr. R. Staward for two bunches of radishes; and Mr. J. Patisson, Rutherford, Roxburgh, for six leeks.

NON-COMPETITIVE.

Messrs. Wm. Cutbush and Son, Highgate, London. — Perpetual-flowering carnations, flowering shrubs, and alpine plants. (Silver-gilt medal.)

Messrs. Dobbie and Co., Edinburgh.—Cinerarias, calceolarias, roses, hyacinths, narcissi, tulips, etc., and potatoes. (Gold medal.)

Messrs. Storrie and Storrie, Glencarse, Perthshire.—Cinerarias (radiata), ornamental borecoles, and Primula obconica gigantea. (Silver-gilt medal.)

Messrs. J. and A. Glass, Edinburgh.—Perpetual-flowering carnations, roses, etc. (Gold medal.)

Messrs. John Forbes, Hawick, Lim.—Alpine and show auriculas, alpine plants, violas, etc. (Silver medal.)

Messrs. Cunningham, Fraser, and Co., Edinburgh.—Collection of choice alpines, arranged on rockery. (Silver-gilt medal.)

Mr. David King, Osborne Nursery, Edinburgh.—Group of tulips, narcissi, and other spring flowers, with background of palms, etc., and flowering shrubs, artistically arranged on floor. (Gold medal.)

Mr. Clarence Elliot, Six Hills Nursery, Stevenage.—Alpine plants arranged on rock work. (Silver medal.)

Messrs. Thyne and Son, Dundee.—Alpine plants. (Silver medal.)

Messrs. Reamsbottom and Co., Geashill, King's County.—St. Brigid anemones. (Bronze medal.)

Messrs. Hogg and Robertson, Dublin.—St. Brigid anemones, narcissi (including new seedlings), and May-flowering tulips. (Silver-gilt medal.)

Messrs. R. B. Laird, Dickson, and Sons, Lim. Edinburgh.—Large exhibit of flowering shrubs, artistically arranged on the floor. (Gold medal.)

Mr. D. McLeod, Chorlton-cum-Hardy.—Orchids.

Messrs. Dicksons and Co., Edinburgh.—New seedling amaryllis, rhododendrons, standard geraniums, roses, etc., artistically arranged on floor. (Gold medal.)

Messrs. Young and Co., Hatherley, Cheltenham. — Perpetual-flowering carnations. (Silver-gilt medal.)

Messrs. J. Piper and Son, London and Barnes, Surrey.—Alpine plants, etc. (Silver medal.)

Messrs. Sander and Sons, St. Albans.—Orchids. (Silver-gilt medal.)

The Liverpool Orchid Nursery (Cowans), Lim.—Orchids. (Silver medal.)

Mr. Theo. E. Dawes, Syderstone Nurseries, Norfolk.—Dawes "Challenge" rhubarb. (Silver medal.)

W. B. Boyd, Esq., Faldonside, Melrose.—Saxifrages and primula.

Mr. T. Highgate, Hopetoun Gardens, Queensferry.—Brachyglottis repanda.

SPECIAL AWARD.

First Class Certificate.—Awarded to Cypripedium Rothlow (Cypripedium Rothschildianum × C. Lowianum). Exhibited by the raiser, Mr. W. Sharp, Freeland Gardens, Forgandenny.

Cornwall Spring Flower Show.

Held at Truro on April 8 and 9, the principal Cornish spring flower show was of unusual interest because the earliness of the season permitted the display of a larger number of flowering trees and shrubs than is usually the case, even in "the delectable Duchy." Daffodils were good and numerous, both trade and amateur growers and raisers contributing excellent exhibits that included not a few new varieties. The rhododendrons were a special feature, their colouring attracting general attention. One particularly good exhibit from the famous gardens of T. B. Bolitho, Esq., at Trewidden, Buryas Bridge, R.S.O., gave striking evidence of the kindly climate of Cornwall, as every truss of bloom had been gathered from out of doors. We present our readers with an illustration of this exhibit, and regret to state that our detailed report of the show has not reached us at the moment of going to press. The presence of an influential deputation from the Royal Horticultural Society lent special interest to the show on this occasion.

SIX VASES OF RHODODENDRON FLOWERS, CUT FROM THE OPEN.
Exhibited by T. B. Bolitho, Esq., Trewidden, Buryas Bridge, at the Cornwall Spring Flower Show, Truro

The Horticultural Club.

On Tuesday, the 1st instant, this club held its usual house dinner at the Hotel Windsor, Mr. G. Munro, V.M.H., taking the chair, and a fair number of members and guests, including some ladies, being present. After the dinner an interesting lecture was given by Mr. J. Edmund Clark, entitled "Some Nature Notes in South Africa," illustrated by a number of lantern slides prepared from photographs taken by the lecturer. These represented a large number of views depicting various aspects of the country and its flora and vegetation generally, including Table Mountain from many points of view, but unfortunately many of the slides were very imperfect as regards illumination and detail, which considerably detracted from their interest.

Royal Horticultural Society.

SCIENTIFIC COMMITTEE.—March 18.

Present: C. E. Shea, Esq. (in the chair); Messrs. E. M. Holmes, A. Worsley, W. Hales, G. Gordon, and F. J. Chittenden.

DAHLIA PLANTS FAILING.—Mr. Mas- reported that the Dahlias sent from Edinburgh in which the buds had failed to start were attacked by the fungus Sclerotinia sclerotiorum.

LATHYRUS SATIVUS (POISONOUS). — Mr. E. M. Holmes showed seeds of Lathyrus sativus and those of Pisum sativum and P. arvense from India for comparison, in order to draw attention to the fact that seeds of the former plant were being sold (under the name of Mutti) for cattle food instead of the latter. They were imported from India and were now to be obtained in various markets. The seeds of L. sativus are poisonous, though the symptoms of poisoning do not always manifest themselves very quickly, and the actual poisonous substance has not been isolated.

HOLLY GROWING ON SHINGLE BEACH.—A correspondent sent a photograph of a fine holly growing on a shingle beach at Lydd, Kent, where also several other unusual plants are to be found growing wild. The bush is a large one, and looked well in the past year.

ALLEGED POISONING BY FERNS.—Mrs. S. Edmonds sent an account of the death of two cats, supposed to have been caused by eating the fronds of ferns in a dwelling-house. One had died, and a second, which later betrayed the same symptoms, which were those of an irritant poison, was killed, as recovery was deemed impossible. The first was not examined, but the second was, and pieces of a fern frond were found in the stomach. The fern was sent for examination, and proved to be Nephrolepis exaltata var. todeaoides. No record of this fern or any of its congeners being poisonous was known to any member of the committee, but the committee would be glad to learn whether animals having access to it have been known to be poisoned. The evidence in the present case seems far from conclusive, but as cats very frequently nibble ferns, and this nephrolepis is very widely cultivated, no doubt if it is really poisonous other cases may be heard of.

SCIENTIFIC COMMITTEE.—April 1.

Present: G. Gordon, Esq., V.M.H. (in the chair); Messrs. A. Worsley, R. A. Curtis, W. Hales, G. Massee, and F. J. Chittenden (hon. secretary).

FASCIATED STOCK.—Mr. H. Stuart Thomson sent from Carquieranne, South of France, part of a fasciated example of Matthiola sinuata bearing hundreds of flowers, and having a stem about $2\frac{3}{4}$ inches in width. Though fasciated plants are very frequently shown before the committee, perhaps more frequently than those showing any other aberration of growth, stocks have rarely or never been exhibited in this condition. The present specimen was growing on the cliff outside an hotel garden, and others there showed a similar habit of growth.

LOCUSTS AND COCONUTS.—Mr. Gilliat sent a note concerning the destruction of seedling coconuts over an area of 500 acres in the Federated Malay States, where the trouble from this pest has recurred in a second year. The use of paraffin had been unsuccessfully tried, and it was suggested that Paris green or lead arsenate should be used, either as a spray or by drenching some locusts collected and slightly crushed beforehand with this poison. Some species of locust are cannibals, and it might be possible to check their ravages by collecting and poisoning some of them in this way.

MALFORMATION IN DOUBLE PRIMULA.—Dr. J. MacWatt, Duns, sent a curious flower from a double primrose seedling; the calyx was much larger than usual, and had double the usual number of teeth. It was surrounded two separate and distinct double corollas, separately inserted on the receptacle and normal in every other respect.

Dundee Horticultural Association.

"The Vine" was the subject of a lecture delivered by Mr. Thomas Wilson, head gardener, Glamis Castle, at the monthly meeting of this society in the Technical College on the 4th inst. Dealing with his subject in an interesting and instructive manner, the lecturer gave sound practical hints on the formation of borders, the planting and care of young vines, training, pinching, pruning, cropping, and thinning of the fruit bunches; the peculiarities of certain varieties were pointed out, and the best methods of preventing and combating diseases and insect pests were described, while the rejuvenation of old vines was also touched upon, although the lecturer rather preferred to plant anew. A lengthy and profitable discussion ensued.

Two exhibits were staged, a good double-spathed arum from Mr. James Bethel, The Grange Gardens, and a well-flowered cyclamen from Mr. I. Staward, St. Fort Gardens, the latter receiving a cultural certificate. Votes of thanks to lecturer, exhibitors, and chairman, Mr. Wm. Christeson, closed the proceedings.

Croydon Gardeners' Society.

A few days ago Mr. Montagu Allwood lectured before this Croydon Society, and his subject was "Perpetual Carnations." There was a very large attendance, and at the close of the lecture Mr. Allwood had to answer a large number of questions. Mr. T. Butcher exhibited forced flowering shrubs; Mr. W. Coles displayed flowering bulbs grown in fibre, and Mr. T. H. West sent excellent trusses of Primula obconica flowers.

Bristol Gardeners' Association.

The recent fortnightly meeting of this association was held at St. John's Parish Rooms, Clifton, Mr. Thoday presiding over a large attendance, when Mr. White, from the Bristol Amateur Horticultural Society, gave a lecture on "Curious Plants." The prizes given by Messrs. Ayres, Binfield, and Woodward, for three vases of stove and greenhouse cut flowers (orchids excluded) were won by Messrs. Scott, Baston, and Jennings. A hearty vote of thanks was accorded Mr. White.

BORDEAUX MIXTURE.

Owing to the good results given by lime and sulphur as an insecticide and fungicide, there has been a great falling off in the use of the Bordeaux mixture. There is no question about the value of both mixtures, but the latter has lost in popularity in Canada owing to its russeting he skin of the apples in many of the best standard varieties. Perhaps too little attention has been given to the preparation of Bordeaux. The general way is to mix it by guess-work, the grower forgetting that the best results are only obtainable where care is exercised in the preparation of any spray mixture.

Bordeaux is a long-established mixture, and we have varying proportions of its ingredients. This is due in part to the desire to arrest the injurious effects above-mentioned. The standard formula is 4lb. bluestone, 4lb. lime, 40 gallons water, known as the 4-4-40. However, formulæ 4-4-50; 2-4-50; 3-5-50 apparently have given good results. Some authorities claim that it is not the strength of the application that does the injury, but that too much spray has been applied. This is a point of considerable interest, for it has been noticed where thorough heavy spraying with Bordeaux is done the greatest injury has resulted.

The point to be most careful of in making is not so much the formula used (if it has been tried), as the way to mix it. The effective part of a good mixture is the blue precipitate which will settle to the bottom of the tank when allowed to stand. This is the portion we are most concerned about. To be of most benefit, then, this precipitate should be as fine as possible, or, in other words, remain in suspension as long as possible.

To get the copper sulphate crystal into solution most quickly, break it into small particles, place in a bag, and suspend in water. If possible, secure the sulphate in the granular form, as it is more easily dissolved. The most convenient way is to mix proportionate amounts of bluestone and water; dissolve 50lb. in 50 gallons of water. Then when this is wanted for use the desired amount can be taken out by measuring, as a gallon of the liquid contains one pound of bluestone. It is necessary to use a tub or barrel to contain this mixture as it is very corrosive to tin or iron.

While the copper sulphate is dissolving, slake the lime, which should be perfectly fresh and in large lumps, by adding small amounts of warm water until it is powdered, then make into a paste. The important operation now is in mixing, or rather in not mixing, the concentrated solutions, for when concentrated solutions are mixed a very heavy precipitate is formed. For this reason the bluestone should be diluted to 20 or 25 gallons with water, the lime to a similar amount, and then the two liquids poured at the same time into the spray tank. Always strain the liquid through a fine wire screen into the tank.

NEW BOOKS.

COMMERCIAL GARDENING.

Edited by John Weathers, F.R.H.S. (The Gresham Publishing Company, 34 and 35, Southampton Street, Strand, London). Four vols. Price 9s. each.

Considering the enormous development which market gardening has undergone during the past thirty or more years, it may appear somewhat surprising that not until the appearance of this work should a book of a really comprehensive character have been published for the guidance of those who are engaged in this and other branches of commercial horticulture. It has, of course, to be remembered that the cultivation of plants, flowers, fruits, and vegetables for profit has now assumed such immense proportions and become so varied that but few writers would be prepared to undertake the difficult task of writing or editing a book in which the several branches of this great subject would be dealt with in a manner commensurate with their relative importance. Fortunately, not all have shrank from the arduous task, and the editor may be commended for the public spirit he has evinced, and be congratulated on the success he has achieved.

The work is published in four volumes of convenient size for everyday use, and within the 1,000 pages may be found information on the various matters to which those engaged in commercial gardening must give their attention. This information is not only given in a manner that it may be readily understood, but it is remarkable for its soundness. This is exactly what might have been expected, for the editor has had a practical experience in the commercial side of horticulture, and he has had the help of a score or so of writers who occupy a high position among those who are engaged in market culture and the nursery trade.

A mere enumeration of the contents of the work would form a lengthy, if not tedious list, and it must suffice to say that they include all that is of importance in the selection, the cultivation, and the selling of the various products of the nursery and market garden. The text is elucidated by a profusion of illustrations, which are not only of a high class, but have evidently been selected with due regard to utility.

To those who are engaged in commercial gardening the work is a necessity, and it is well deserving of the attention of those who have the management of private gardens, and are desirous of embodying in their practice some of the methods of the grower for market.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the Gardeners' Magazine, 148 and 149, Aldersgate Street, E.C.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the Gardeners' Magazine, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the Gardeners' Magazine. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to druw attention, correspondents are requested to distinctly mark the paragraph.

ORIGIN OF MADRESFIELD COURT GRAPE.—N. K. D., Chester: I shall be greatly obliged if you will give me the origin of Madresfield Court grape, as I propose making some grape crosses, and should therefore be glad to know the parents of this fine variety.—Madresfield Court grape was raised by Mr. William Cox, who was head gardener to Earl Beauchamp, at Madresfield Court, Worcestershire. He crossed Muscat of Alexandria with Morocco, and thus produced this excellent grape. Madresfield Court gained a First-class Certificate from the Royal Horticultural Society in 1868.

PROPAGATION OF SEMPERVIVUMS.—S. E. G., Topsham: Please state in an early issue the best means of increasing stock of the various sempervivums, or houseleeks.—These interesting plants may be propagated from seeds sown, as soon as ripe, in pans of sandy soil, in a cold frame. They may also be increased readily by detaching the young plantlets that appear around the base of the parent stem, or from the axils of the lower leaves.

MILDEW ON ROSES.—W. S., Chingford: I have a few roses in pots, and most of them are doing well; but several plants have what I suppose to be mildew on the foliage. I am an amateur, and have derived very great benefit from the instructions given in the Gardeners' Magazine, which I have taken regularly during the past two years, therefore I take the liberty of asking what should be done with the affected plants.—Dry flowers of sulphur applied by means of special bellows, or a puff-ball arrangement, is an excellent remedy for mildew. Dust the sulphur on leaves and shoots so as to form a thin coating. A second application may be necessary in the course of a week or so. Sulphide of potassium is another excellent remedy, and is made by dissolving a half-ounce of sulphide in hot water, and adding tepid water to make up one gallon. It is a good plan to place the sulphide in about a pint of water, in an earthen jar, standing the jar in a vessel of water over the fire and allowing the sulphide to dissolve by the boiling of the water in the jar.

SEEDS OF A MEXICAN SHRUB.—A. P. C., Blackwater: Some seeds of a Mexican shrub have been sent me, and the only name given is Montanoa, but I am told the leaves are handsome, being much divided, but that the flowers are not very showy. With this meagre information, is it possible for you to determine the plant, and suggest how it should be grown?—We feel certain you have seeds of Montanoa bipinnatifida, a tender shrub with handsome bipinnate leaves. It grows six or eight feet high, and is sometimes used during the summer to lend a sub-tropical effect to warmly-situated gardens. Sow the seeds at once over gentle bottom heat, and as the plants grow give them additional root room and cooler quarters until they are hardy enough to be stood out of doors, say, in July, or they may be kept for the adornment of the conservatory. If a root is placed in heat in January new growths will appear, and these may be propagated easily after the manner of dahlias. Single-stemmed plants grow in this way and gradually hardened off for the conservatory or the flower garden are very effective. Rich loamy soil provides a suitable rooting medium. Montanoa bipinnatifida is a member of the Natural Order Compositæ, and it is sometimes known as M. heracleifolia, or Polymnia grandis.

STOCK SOLUTION OF POTASSIUM SULPHIDE.—M. E. J., Morpeth: Can you tell me whether it is possible to make up a stock solution of sulphide of potassium, from which one could easily prepare a spraying mixture without the trouble of dissolving an ounce or two of the sulphide as the material was needed? Last year I found this fungicide extremely useful, but the preparation of a few gallons every week proved very irksome. Any help will be greatly appreciated.—It is generally considered that freshly-made solution is the most effective. We are not aware that any definite experiments have been made to prove or disprove this. A stock solution will keep good for a considerable time, provided it is kept in a dark place. If a pound of sulphide is boiled as advised in the answer to "W. S.," and made into a stock solution of three pints, then two fluid ounces of it should be added to a gallon of water for spraying. The addition of the whites of a couple of eggs to the stock solution will lend just sufficient adhesiveness to the spraying mixture.

HYACINTHS FAILING TO FINISH THEIR SPIKES.—S. T. S., Tamworth: Some of my hyacinths have failed to finish their spikes this year. Growth was first-rate, and the spikes seemed to be of good size and strength, but the apex failed to develop properly, and numerous flowers did not open at all. I enclose one or two examples, and shall be very glad to learn the cause of this failure.—The failure is not necessarily due to any cultural error, but is most likely the result of improper ripening of the bulbs last summer. You will remember that the season was not a good one for bulbs, as the spring was early and warm, causing premature growth and a rapid development of foliage that was detrimental to the formation of the embryo spike for another year and the consolidation of the bulb. Then followed a long cool, wet season, and so the bulbs did not have that decided rest which is essential to their well-being in the future. We have seen many spikes similar to those sent, and we believe the explanation we have given is the correct one in such cases.

MOLTKIA.—N. T. D., Westcott: A friend has sent me a little shrubby plant which is said to come from Dalmatia. It bears some resemblance to a rosemary, and my friend tells me it is called a Moltkia. Will you please tell me the correct name, if that is possible from this meagre description, and also say what position in the garden the plant should occupy. For the time being it is in a cold frame.—So far as we can determine we believe your plant is Moltkia petræa, also known as Lithospermum petræum and L. rosmarinifolium. This little shrub has a strong resemblance to a dwarf rosemary bush, and has greyish linear leaves. From May onwards to July it should produce flowers that are rosy purple at first but change to rich violet-blue. Give it a sunny position in sandy soil, either in the border or on the rock garden. During the summer take a few cuttings and place them in very sandy soil in a close frame.

SOWING SALSAFY.—C. M., Salisbury: What is the best time to sow salsafy? I have delayed sowing because previously many of the plants ran to flower.—A good time for sowing salsafy is the third week in April; sown at that date there is little likelihood of the plants running to flower.

SELECTION OF EARLY-FLOWERING CHRYSANTHEMUMS.—F. H., Lincoln: Please give me a selection of a score or two dozen varieties of good early-flowering chrysanthemums.—The following are all excellent varieties: Almirante, chestnut-crimson; Bronze Goacher, bright bronze; Caledonia, white; Carrie, deep yellow; Chatillon, salmon on gold; Cranfordia, golden-yellow; Cranford Pink, soft pink; Ethel Blades, chestnut-scarlet; Goacher's Crimson, rich crimson; Goacher's Pink, rich pink; Harrie, bronzy orange and gold; Horace Martin, yellow; Leslie, brilliant golden-yellow; Marie Masse, mauve; Nina Blick, reddish bronze; Norbet Purvis, salmon; Normandie, pink; Perle Chatillonaise, cream and peach-pink; Polly, orange; Provence, rich pink, gold tipped; Ralph Curtis, cream-white; Roi

"ABOL"

— INSECTICIDE —

Now acknowledged to be the world's Best Pest Destroyer — Safe, Certain, Reliable and

NON-POISONOUS

The great remedy for all Garden Pests, MILDEW on ROSES and other plants.

Used at the Royal Gardens, Kew, White City and Hampton Court Gardens.

LAYERING FORSYTHIAS. — G. P., Christchurch: A friend of mine tells me that forsythias can be easily multiplied by means of layers. Is this right, and, if so, how should I proceed?—The forsythias may be propagated either by layering or by means of cuttings. The latter may either be green shoots struck in summer under handlights, or ripened wood inserted in autumn and kept in cold frames all through the winter. Layering is the easiest possible method of increasing stock, and any long shoot may be pegged down for the purpose. There is no need to notch or "tongue" the nodes, or joints, as roots come quite naturally.

PLANTING MONTBRETIAS.—S. T. B., Oswestry: I have recently taken over a new garden, and, fortunately, the soil and general conditions are good. Montbretias have appealed to me in recent years, and so I propose to plant some if the season permits. Kindly tell me the best time to plant.—Planting may be done at once if soil and weather are favourable, but any time during April will do very well. In addition to the newest variety Star of the East, excellent sorts are Prometheus, George Davison, Hereward, Lord Nelson, King Edmund, Lady Hamilton, Westwick, and Germania.

NAMES OF PLANTS.

H. T. S., Ware. — Hardenbergia Comptoniana.

C. H., Hailsham.—1, Prunus avium; 2, Berberis stenophylla; 3, Primula rosea.

E. D., Dorchester.—1, Prunus persica fl. pl., var. carnea; 2, Anemone hepatica; 3, Erica mediterranea.

S. W., Ripon.—1, Euphorbia splendens; 2, Asplenium nidus; 3, Begonia metallica; 4, Leea amabilis; 5, Helxine Solieroli.

M. N. R., Hitchin.—1, Magnolia stellata; 2, Primula frondosa; 3, Doronicum plantagineum; 4, Berberis stenophylla; 5, Scilla biflora.

P. C., Merstham.—1, Mahonia aquifolia; 2, Cupressus macrocarpa; 3, C. torulosa; 4, Monochætum Hartwegianum; 4, Dendrobium bigibbum.

D. D. F., Llandaff.—1, Erica carnea; 2, E. Veitchi; 3, Anemone nemorosa; 4, A. apennina; 5, Amelanchier canadensis; 6, Corylopsis spicata.

B. L. A., Cirencester.—1, Probably Helianthemum vulgare, send when in flower; 2, Omphalodes verna; 3, Streptocarpus Rexi; 4, Dracæna Lindeni.

A. A., Exmouth.—1, Prunus subhirtilla; 2, Ligustrum lucidum; 3, Erica carnea; 4, Anemone pulsatilla; 5, Vaccinium pennsylvanicum; 6, Veronica Hectori.

TRADE NOTE.

A USEFUL WEED KILLER.

Good gardeners will all agree that tidiness and neatness are two of the principal assets of a successful gardener, and it may therefore be argued that preparations which tend towards the achievement of such desirable results are worthy of the attention of horticultural enthusiasts. Feeling assured of this we are glad to have the seasonable opportunity of referring to the well-known and effective "Eureka" Weed Killer, made by Messrs. Tomlinson and Hayward, Lim., Lincoln. This preparation has stood the test of time, and is esteemed because it can be used with comparative safety under almost any conditions. One or two applications on paths or walks at the present time will have a permanent effect, not only in removing existing eye-sores, but in preventing their recurrence for some time to come. The "Eureka" Weed Killer is supplied through agents, but if any difficulty is experienced in obtaining, write to the makers, who have a useful range of sundries required by all gardeners.

FORTHCOMING ENGAGEMENTS

NEXT WEEK.

MONDAY, April 14.—Annual meeting of the United Horticultural Benefit and Provident Society at the Royal Horticultural Hall, Westminster, at 8 p.m.

TUESDAY, April 15.—Royal Horticultural Society's Daffodil Show; Narcissus Committee meets at 11.30 a.m.; Fruit, Floral, and Orchid Committees at 12 o'clock; Scientific Committee at 4 o'clock. Lecture at 3 p.m. on "The Origin of Life: Why it is Undiscoverable," by Rev. Professor G. Henslow, M.A., V.M.H.

WEDNESDAY, April 16.—Second day of Royal Horticultural Society's Daffodil Show. Primula Conference at Royal Horticultural Hall, from 11 o'clock to 1 o'clock, and 2 p.m. to 4 p.m.
Royal Horticultural Society of Ireland, Spring Show.
County Clare Spring Show.

THURSDAY, April 17.—Ipswich Spring Show.
Linnean Society Meeting.

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.
Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.
Ealing Horticultural Society, July 9.
Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.
Ulverston Rose and Sweet Pea Show, July 18.
Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.
Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.
Tunbridge Wells Flower Show, July 23 and 24.
St. Quintin Horticultural Society, July 24, in the Gun Club grounds, Wood Lane, W.
City of London Rose Show, July 26, at Cannon Street Hotel.
Worth Horticultural Society, July 30.
Datchet Horticultural Society, August 4, at The Lawn.
Oswestry Flower Show, August 4.
Ranmoor Floral and Horticultural Society, Aug. 4.
Bletchley and Fenny Stratford Horticultural Society, August 4, at Bletchley Park.
Swanage Horticultural Society, August 4.
Westbury Horticultural Society, August 6.
Horsley Horticultural and Cottage Garden Society, August 16.
Aynho Horticultural Society, August 19.
Brighton Summer Show, August 19 and 20, in the Dome and Corn Exchange, and on the Western Lawn.
Kiddington Horticultural Society, August 21.
Ashton-under-Lyne Horticultural Association, September 6.
Maidenhead Chrysanthemum Show, October 30, at the Drill Hall.
Bath Chrysanthemum Show, November 5 and 6, at the Roman Promenade.
Brighton Chrysanthemum Show, November 11 and 12, in the Dome and Corn Exchange; thirty-first exhibition.
Bedford Chrysanthemum Show, November 12.
Chester Paxton Society's Chrysanthemum Show, November 18 and 19, in the Town Hall, Chester.

MARKETS.

COVENT GARDEN.

Flowers.

A steady demand prevails for daffodils, tulips, carnations, and roses. White flowers have been in great request this week.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Beauty and Utility.

If we study the beauty of infinite forms of life which exist upon the surface of the earth and in the depths of the ocean, the beneficence which underlies the whole scheme of creation is emphatically brought home to us by so much of this beauty appearing to be absolutely independent of actual utility, and, to that extent, a free addition to the joy of existence. For the mere practical working of the vital forces organisms of the simplest possible character, devoid of any special charm of form or colouration, are as fully qualified as the most complex. A simple nucleated cell, as in amœba, which may be described as a shapeless morsel of jelly with a dot in the centre, is as devoid of any element of beauty as may well be conceived, yet it can move itself, feed itself, asd reproduce itself to perfection, so that as a fundamental of vital action, beauty or æsthetic charm is totally unnecessary. Nevertheless, starting with some such elementary life beginning, we see, as evolution proceeds, that in the simple agglomeration of cells, symmetry of form and regularity of arrangement speedily produce organisms of great beauty. Take, in the plant world, the volvox found in stagnant water. Here we have a wonderfully perfect sphere formed of a multitude of single cells, each provided with a cilium of microscopic filament, and by means of their united action the sphere revolves in its watery realm, as majestically as a world might do in its ethereal one, while, wonderful to relate, we can detect through its translucent emerald walls smaller spheres built on like lines which are eventually destined to free themselves and imitate their roving progenitor. No jeweller could equal so beautiful a gem, yet, charming as it is, it cannot excel the shapeless amœba in its powers of motion, assimilation, and reproduction. Its charm, to the human eye, when adequately viewed under the microscope, can hardly involve any utility to itself; it is a thing apart, engendered in our mind, due to the action of the great laws of Nature, which of themselves have determined our ideas of what we call beauty, and require a liberal education to properly appreciate. The untutored savage probably sees little or no beauty in his surroundings, the grandest landscape only appeals to him as a hunting ground, while, on the other hand, as we know, he and his squaws may, in their own opinion, decorate and "beautify" themselves in fashion which we ridicule as "hideous." Where, however, Nature is left alone, if "hideousness" appears, as it certainly does in some of her productions, they are the exceptions rather than the rule, and there is no doubt that in most cases their ugliness, from our point of view, has been an evolutional factor, protective or otherwise. In this connection, could we meet with Dame Nature as an actual personality, we would welcome from her an article for our columns on that floral "beauty" which our florists have in many cases evolved from her normal and simpler gems, though we very much doubt that it would meet with her unqualified approval. Since, however, man came on the scene as a potent evolutional factor, his "taste" as regards the "beauty" of the floral world, to say nothing of the animal one, from which he has also evolved some marvels, "beauty" has become a distinctly useful character in securing reproduction, and what he considers improvement in a vast number of plants, which otherwise, as wild ones, would have been comparatively rare, and wholly neglected. Nature, it is true, can still rival his best productions with many of her entirely unsophisticated ones, but these last are becoming fewer and fewer in comparative ratio with those which, starting as purely normal forms, have yielded to the persuasion of the selective cultivator, and are being replaced by plants of enhanced beauty derived from them. Or they may be, as in the begonias, due to combinations of several species whose complex offspring far and away eclipse in beauty, size, colour, and diversity anything that unaided Nature would have been likely to effect even by æons of evolution. Beauty here has undoubtedly been a useful factor, and has, in point of fact, determined the existence of a myriad forms, where, without its attraction, only a very few would have seen the light. The immense utility of cultivated flowers for decoration is, of course, outside the point of view we have started with, only the utility of beauty to the plants themselves being regarded as a vital factor.

MR. P. RUDOLPH BARR,
Who has been awarded by the R.H.S. Narcissus Committee the Barr Memorial Cup for the ensuing year.

Mr. P. Rudolph Barr, who is well known as the senior partner in the firm of Messrs. Barr and Sons, Covent Garden, and for his work in connection with daffodils, was on Tuesday last awarded, by the Narcissus Committee of the Royal Horticultural Society, the Barr Memorial Cup for the ensuing year. This cup, which was founded last year by public subscription to commemorate the splendid work accomplished by the late Mr. Peter Barr, V.M.H., in the course of his long and active life, in developing and popularising daffodils, is held for one year, and the first recipient was the Rev. G. H. Engleheart, V.M.H., who was one of the first of the amateurs to recognise the possibilities

of the creation of new narcissi. It is of much interest that the love for, and interest in, the daffodil which were evinced by the late Mr. Peter Barr should have been inherited by his talented sons, and that, as the result of this affection, combined with judgment of a high order, the firm should now be as closely identified and as actively engaged in the creation and distribution of new forms as at any period in its history. Apart from the commercial aspect of these beautiful flowers, Mr. Rudolph Barr has for many years past devoted much personal attention to them, and has long been regarded, and properly so, as one of the leading authorities on them. His thorough acquaintance with varieties was well shown by the valuable service he rendered in the classification of daffodils which was accomplished by the Royal Horticultural Society's Narcissus Committee a few years since, and it has also been exemplified in no uncertain manner by the success he has achieved as a raiser.

Appointment of Assistant Inspectors of Horticulture.—Three Assistant Inspectors of Horticulture have been appointed in the Horticultural Branch of the Board of Agriculture. These are Messrs. R. H. Lock, Sc.D., J. Snell, B.Sc. and H. V. Taylor. Dr. Lock was for some years Curator of the Cambridge University Herbarium, and during the past four years has been Assistant Director of the Royal Botanic Gardens, Ceylon. Mr. Snell has for some time been Lecturer on Botany at the Birkbeck College, and Demonstrator in Histology at the Middlesex Hospital. Mr. Taylor was educated at the Royal College of Science, South Kensington, and at the time of his appointment held a scholarship at the college, awarded for the purpose of studying plant diseases. Mr. Snell and Mr. Taylor are the sons of farmers.

Lingering Winter.—The weather experienced during the closing days of the week ended April 12 was wintry in character, and did considerable damage to tender vegetation over the greater part of England. On the 11th inst. there was a comparatively heavy fall of snow in the more easterly and northern parts of the country, and daffodils were weighed down by their fleecy covering, and suffered accordingly. On the 12th inst. the temperature was exceptionally low for the season throughout the day, and during the night there was a severe frost, which did much damage to plants in bloom. In the Royal Gardens, Kew, Magnolias conspicua and Soulangeana in the azalea garden, which were then in full bloom, had the greater part of their flowers destroyed, as did the elegant Magnolia stellata. The group of the double-flowered peaches near the Victoria Gate, which were then at their best, had many of their blossoms injured, and thereby bereft of much of their beauty. Ornamental crabs, of which several were coming into bloom, also had their flowers damaged. During the 12th inst. the mean temperature at Kew was 41 deg., or about 14 deg. below the average. The weather records of the metropolis during the past 40 years show that such low day temperatures in April are very rare. In fact, in the whole of the past four decades there were in the metropolis only three days in April with a lower temperature. These were April 13, 1892, when the shade temperature was 40 deg.; and April 5 and 6, 1911, when it was 38 deg. It is of some interest that on the two last-named dates the thermometer was higher in London than in some parts of the South of England. For example, on April 5, 1911, the temperature in the Isle of Wight was 35 deg., at Weybridge it was 34 deg., at Worthing it was 32 deg., and at Tunbridge it was 31 deg. Night frosts were of exceptional severity in the early part of April two years ago, and extended over a wide area, and did an immense amount of damage to fruit crops; and in the Channel Islands the potato crops were seriously injured. As indicating the variability of the weather in April, it may be mentioned that on April 25, 1874, the shade temperature in London was 80 deg., and on April, 1893, it was 82 deg. There can be no doubt that considerable damage was done to the blossom of fruit trees in flower, and we shall greatly appreciate communications from our readers with reference to the damage done.

American Gooseberry Mildew in Kent.—A report showing the serious spread of American gooseberry mildew in Kent was submitted to the Kent County Council at Maidstone at their meeting for the current month by the Diseases Committee. According to this report there is now a total infected area of 3,353 acres. The report mentioned that an unsatisfactory feature with regard to the disease was the great difficulty inspectors had in inducing growers to comply with notices requiring them to cut out the diseased shoots within a prescribed time.

THE BARR MEMORIAL CUP.

Forestry at the "Royal" Show.—As for some years past the Royal Agricultural Society will give special attention to forestry at the annual exhibition which this year will be held at Bristol in July. The schedule of the forestry exhibition, which will be arranged in the showyard contains twenty-two sections, more than half of which are competitive. In the several sections may be shown seedling trees, transplanted trees, boards of different kinds of timber, tree guards, field and hunting gates (which must be made by the exhibitor's own estate staff), fencing of home-grown and foreign woods, specimens showing damage done by insect and fungoid pests, the effects of pruning, creosoting and other means of wood preservation, and photographs, plans, maps, and models. The schedule for the forestry competition beyond the boundary of the showyard contains four classes for plantations, the final crop of which is to be hard woods, and four to plantations in which conifers are to be the final crop. There is a class for plantations of the rarer conifers, such as the Douglas fir, the Sitka spruce, the Japanese larch, and the Corsican pine, and also one for the best example of systematic management of existing woodland areas. Home nurseries have three classes set apart for them. Schedules may be obtained from Mr. T. McRow, secretary of the R.A.S.E., 16, Bedford Square, London, and the entries must be received by Mr. McRow not later than May 20.

Mr. Joseph Smith, the superintendent of the Public Gardens of Eastbourne, celebrated his 80th year the other day, and received many congratulations, among them being those from the employees of the Corporation under him. Mr .Smith has held his present position nearly 28 years, and of his achievements during this period may be mentioned the planning and formation of the gardens on the sea front, which from the first have proved an immense attraction. He is as alert and active as the average man twenty years his junior, and personally superintends the whole of the work that is being done in the open spaces belonging to the town. Mr. and Mrs. Smith celebrated their golden wedding about a year since, when the respect in which they are held was evidenced by the public presentations made to them.

The Rose Annual for 1913 has been issued, and the members of the National Rose Society, who receive a copy as part of their yearly privileges, will have full justification for indulging in a strong sense of satisfaction. The publication is more bulky and more profusely illustrated than either of its predecessors, and the high quality of both illustrations and text has been maintained. The half-tone blocks are this year supplemented by four coloured plates of subjects photographed in their natural colours at the society's autumn exhibition. These comprise a pyramidal arrangement of the rich yellow Rayon d'Or, a basket of twelve blooms of the brilliant crimson-scarlet Hugh Dickson, the first prize eighteen blooms in the nurserymen's section, and a basket of the orange-pink Irish Elegance.

British Association.—Sir Oliver Lodge has been elected president of the British Association in succession to the late Sir William White, for the meeting which will be held at Birmingham in September next.

The Gardens of Skibo Castle, the Sutherland residence of Mr. Andrew Carnegie, are remarkable for their roses, for these fragrant flowers have been planted in prodigal profusion, and thrive amazingly under the conditions that obtain in the northern part of Scotland. Rambling and dwarf roses are both grown in large numbers, and with an equal amount of success. Of great beauty is the effect produced by the roses that fill the eight large beds which encircle the fountain that forms so conspicuous a feature of the gardens. Each bed contains about 450 plants, and conspicuous among the varieties are Madame Abel Chatenay, Madame Ravary, Frau Karl Druschki, Juliet, Lady Battersea, Mrs. John Laing, and Richmond. There are rustic posts rising to a height of eight feet, clothed with Dorothy Perkins, Blush Rambler, Hiawatha, and other varieties of the same class, a hedge composed of the richly-coloured Gruss an Teplitz, and a pergola some 600 feet in length, on which the various climbing and rambling roses are displayed to the greatest advantage. Most delightful also is the effect produced by the roses that clothe the balustrades which support the terrace

...ays. Of the many varieties grown, Countess of Gosford, Frau Karl Druschki, General McArthur, Hiawatha, La France, Liberty, Juliet, Madame Abel Chatenay, Richmond, and White Killarney are special favourites with Mrs. Carnegie.

Fruit Growing in Western Australia.—In the course of his evidence, recently given before the Federal Fruit Commission, Mr. J. F. Moody, the Fruit Industries Commissioner in Western Australia, stated that this year there are 25,000 acres in the State under fruit, as compared with 22,000 acres in the previous year, showing an increase in planting at the rate of 3,000 acres per annum. Referring to the quality of the fruit grown in Western Australia, as compared with that of the Eastern States, he said that the chief difference was that most fruits in the Western State had a much tougher skin, and it was just this difference which gave the Western Australian product its superior export value. He believed that Western Australia was destined to become one of the leading fruit-exporting countries of the world, not excluding America. The Chairman of the Commission, who is a prominent fruit-grower of Sydney, commended generally the quality and character of the orchards and the up-to-date methods employed.

The Bletchley and Fenny Stratford Horticultural Society, which holds its fourth annual exhibition on August Bank Holiday (August 4) in the grounds of Bletchley Park, kindly lent by Sir Herbert Leon, Bart., is a society that has come into front rank with marvellous rapidity. About 140 classes are provided for garden produce, in addition to divisions for poultry, honey, and industrial work. The horticultural section is by far the largest, but considerable attention is devoted to athletic sports, and to the exhibition of horses and ponies. That the whole affair is a great attraction for the Bletchley district will be gathered from the statement that in 1912 the gate money amounted to £415 8s. 6d., and entrance fees to £36 9s. 10d. Subscriptions and special prizes added £129 2s. 6d. to the receipts, and other items brought up the income to £853 15s. 8d. for that year. After distributing £213 10s. in prizes, paying £26 10s. for bands, £113 17s. 2d. for printing, stationery, and advertising, £89 6s. 1d. for tents, etc., presenting the secretary with an honorarium of £50, and defraying a number of petty expenses, the society wound up the season with £110 16s. on the right side, which, with £9 11s. 5d. brought forward, gave the committee £120 7s. 5d. in hand to start with in 1913. Well done, Bletchley!

Horticultural Education in America.—Discussing why it is that graduates from horticultural schools do not gravitate to the best positions in nurseries, the Editor of "The National Nurseryman" (U.S.A.), considers that "the boy who goes through the public school, then through the high school, and then to a horticultural college, is too long before he gets in contact with the soil and hard productive work. There is rarely a position open on a nursery for such a man, and few have grit to begin at the bottom and work up, even with their educational equipment. The educational method is wrong; there is too much horticultural book learning in the beginning. The ideal course would be a good common school education followed by four or five years apprenticeship on a good nursery or horticultural establishment, followed by a two-year course at an experiment station or college. This is the plan followed by Kew Gardens, and is eminently successful as far as turning out practical, well-equipped men is concerned. Encourage the boys to take a four year course on the nursery before they are twenty-one years of age, and then when they do take their horticultural course at college it will count for something, and will not spoil them as practical nurserymen. It is essential they work at 'the bench' at the same time they are studying, before they get too old, and the horticultural schools only play at work."

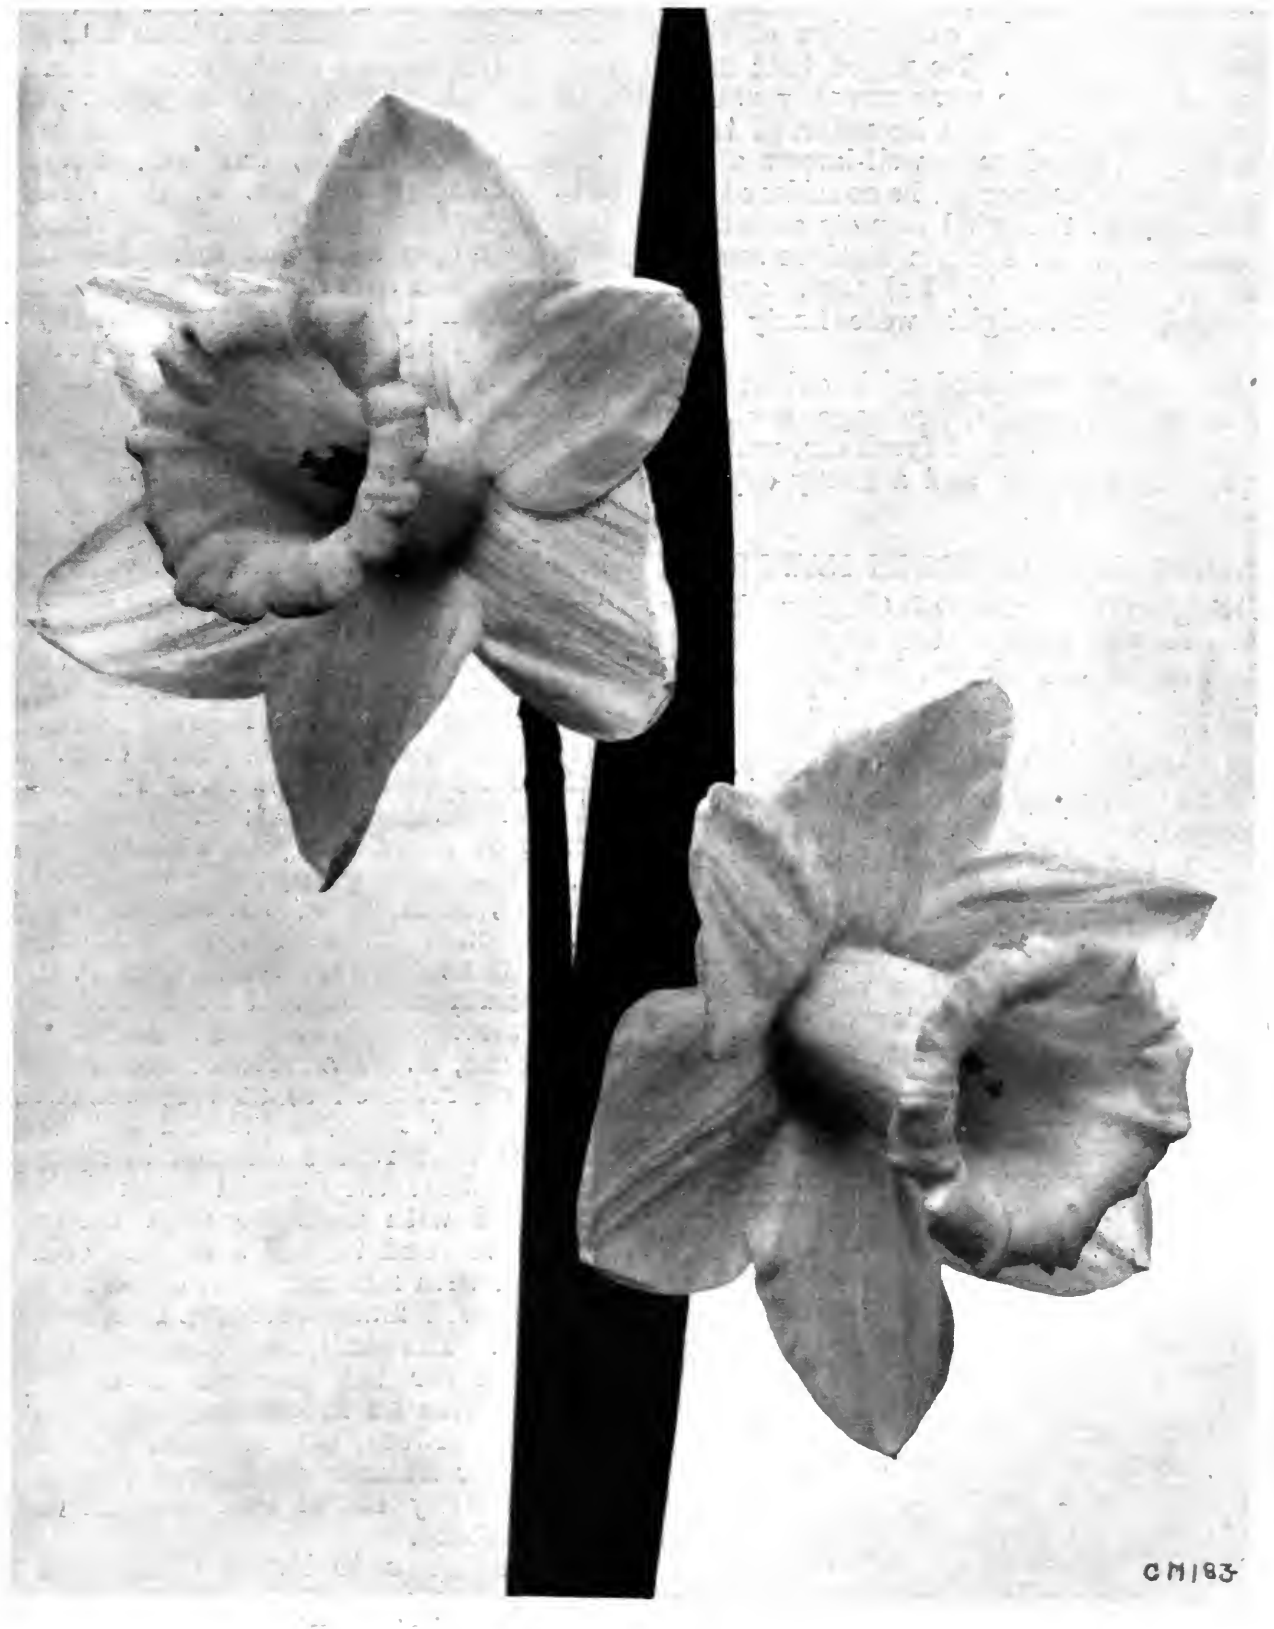
Wintry Weather in Norfolk.—Our Norwich correspondent writes: Norfolk, and especially that part of the county around Norwich, felt the full effects of the wintry weather experienced on the 11th inst. The fall of snow was equal to an average depth of about five inches, and with a strong wind blowing much damage was done to the spring flowers in the majority of gardens. The narcissi appear to have suffered the most severely from the inclemency of the weather, and, generally speaking, the flowers were at their best, but the weight of the snow brought them to the ground, and thousands were utterly ruined. On the morning of the 12th inst. a frost followed, but previous to this much damage had been done to the plum blossom by cutting winds, which had shrivelled tender subjects as if they had been burned."

PRIMULA CONFERENCE.

There was a fair gathering at 11 a.m. on Wednesday, April 16, when Sir John T. D. Llewelyn, Bart., of Penllergare, Swansea, opened the Primula Conference in the Lecture Room at the Royal Horticultural Hall, Westminster. Among those present were: Professor I. Bayley Balfour, Sir Harry J. Veitch, Rev. W. Wilks, and Messrs. H. J. Elwes, R. Wallace, D. Houston, W. Hales, W. Irving, R. L. Harrow, A. Watkins, W. Watson, E. H. Jenkins, C. E. Pearson, F. Chittenden, J. Fraser, Miss Willmott, J. B. Farmer, etc., etc.

Sir John said that it was in 1886 the previous Primula Conference was held under the auspices of the Royal Horticultural Society, and since that time our knowledge of primulas had advanced greatly, and justified the present conference. A great love of primulas had developed meantime, and there had been large discoveries of new species in China, especially in Western China. He referred to the losses sustained in the primula world since the previous conference, and cited Sir J. D. Hooker, Shirley Hibberd, Dr. Masters, Rev. F. D. Horner, B. Simonite, and Jas. Douglas.

Sir John dealt with the garden value of the primula, and, instancing the development of many species in the hands of the florists, pointed out the possibilities of the future with the newer introductions.



NARCISSUS MRS. ERNST KRELAGE.

A very beautiful Ajax variety, white, with creamy-white, frilled trumpet, and of splendid proportions. A most refined flower, although also a large one. A.M., R.H.S., in 1912; and F.C.C., R.H.S., April 15, 1913. Messrs. E. H. Krelage and Son, Haarlem, Holland.

A collection of natural hybrid primulas from Mr. R. Farrer; some from Kew; a fine series of new species from the Edinburgh Botanic Gardens; and a large number of primroses, single and double, from Dr. MacWatt, illustrated the various lectures.

EUROPEAN PRIMULAS.

Dr. J. MacWatt, of Duns, Berwick, who for many years has taken a keen interest in hardy primulas, and has formed a large collection of species and geographical forms, and has also taken up garden primroses and raised a number of double forms, showing distinct colouring, read a lengthy paper upon "European Primulas," and illustrated his remarks with a large number of lantern slides. Some of the slides illustrated specimens growing in their native homes, while others represented specimens growing in Dr. MacWatt's garden.

Many rare species were dealt with, and some directions for the cultivation of these rare kinds were given. He urged that not a few kinds in commerce were wrongly named, notably P. viscosa, which he referred to P. hirsuta, but P. frondosa, a well-known alpine gem, and a popular species, he considered was correctly named, though botanists sometimes think otherwise. P. hirsuta Balfouriana, P. Allioni, P. minima, P. Palinuri, and P. acaule Evelyn Arkwright were finely illustrated.

Dr. MacWatt concluded with cultural remarks as to soil, shade, drainage, etc., and he emphasised the need of fresh air, moisture in spring and summer, and a fairly dry condition during winter.

EUROPEAN HYBRIDS IN NATURE.

Mr. Reginald Farrer, of Clapton, Yorks, who has ranged most of the European Alps in search of alpine plants, has become intimately familiar not only with the species of primulas, but with the vast number of natural hybrids to be found in nature. His paper was a delightful one to listen to, and it conveyed a vast amount of first-hand information, together with opinions respecting the origin of many kinds, formed as a result of close observation during his plant hunts. He pointed out that crosses between primula species of different sections were rare and problematic; between species of the same subsection crosses are rare, except in the subsection Auricula. The two most prolific plants were, Mr. Farrer declared, undoubtedly P. minima and P. Auricula, these having a wide range, and thus coming into contact with many species that are more or less local. P. Auricula crosses freely with P. hirsuta (P. viscosa of gardens), and Mr. Farrer urged the use of the name pubescens for the whole large range of these hybrids, many of which, notably "Mrs. J. H. Wilson" and "The General," are of great garden value. He said that the most wholesale parent was P. minima, and all its hybrids are of use and interest, but, curiously enough, while P. minima crosses readily with very many species, it appears to spurn the attentions of P. Auricula. Mr. Farrer considered P. intermedia, P. Steini, and the fragrant violet-coloured P. glutinosa as the finest of the natural hybrids. P. viscosa he considered was also a common parent. He referred to many kinds which might be hybrids between certain species, but which he did not feel sure of at present; however, he believed there were many good natural hybrids yet to be determined.

To his entertaining and instructive paper Mr. Farrer appended a table of primula crosses, the genus being suitably divided into its several sub-sections. He concluded by asking for a wider cultivation of these natural crosses, and urged that certain hybrids, such as Kellereri, Forsteri, pubescens, Heeri, and the magnificent intermedia, should rank, for show, ease of culture, and general garden value far above any of the species, except spectabilis, Clusiana, marginata, carniolica, piedemontana, hirsuta, and Auricula.

Mr. Farrer is an enthusiast, and he glorified his subject so admirably that one began to imagine every primula was a yard high, with flower heads two feet across, and blooms not less than three inches in diameter; indeed, it almost seemed that this world was made especially for primulas, and all other flowers were accidental, but, after all, the enthusiast makes for progress.

CHINESE AND JAPANESE PRIMULAS.

The afternoon session began at 2 p.m. Professor Bayley Balfour did not read his paper on "Japanese Species of Primula," but referred to the newer Chinese species, as they were portrayed upon the screen. He pointed out that owing to recent explorations there were now about 150 Chinese species known, many of these having been originally found by Roman Catholic missionaries. So far, however, only a small part of China has been carefully explored, and the introduction of many species to cultivation was due to Messrs. J. Veitch and Son, through their collectors, Messrs. Wilson and Purdom, and to the Messrs. Bees, through Mr. Forrest and Mr. Kingdon Ward. At present, the Professor said, Mr. Kingdon Ward was still collecting in China, and Mr. Forrest was also collecting for Mr. J. C. Williams, of Caerhays Castle, Cornwall, so many other species might be hoped for. He said that Yunnan had provided a large number of the known Chinese species, but by means of a map he showed that at present we are only touching the fringe of Chinese primulas.

Professor Balfour is an enthusiast, and his observations upon the species illustrated were great appreciated. He showed P. sinensis and P. obconica, and noticed that the former, stable in the wild state, had varied greatly under cultivation, whereas the opposite was the case with P. obconica, and yet the two species grew side by side in China. He drew attention to P. obconico-Listeri, a species likely to prove of great garden value because it had the good points of P. obconica minus its stinging hairs. P. Veitchi, of the cortusoides section; P. pycnarova, and a series of woodland plants comprised in the P. geranæfolia group; the beautiful spicate species, such as P. Littoniana, P. spicata, P. nessensis, P. secundiflora, and P. pinnatifida; the miniature kinds, like P. umbrella, P. membranifolia, and P. Kichenensis; and the stronger-growing P. serratifolia, P. Beeseana, P. pulverulenta, and P. Bullyana, were all referred to as very beautiful.

Professor Balfour pointed out that some species were rather difficult to manage, and he felt that they would often do better if supplied with moisture from below instead of above, and that if a longer, cold resting period, with less moisture, could be provided, he believed many cultural difficulties would vanish. The statement that £3,000 had been granted for the erection of a large cool-house, with an indoor rockery, at the Edinburgh Gardens, was received with applause. Professor Balfour considered that in such a house many choice species could be grown successfully.

In addition to living plants and lantern slides, Professor Balfour had a large collection of photographs or rare species showing the latter as growing or as dried herbarium specimens. The lecturer was very heartily applauded at the conclusion of his remarks.

Mr. Elwes suggested a refrigerating apparatus to keep such a house as Professor Balfour had suggested sufficiently cool to ensure the plants having a long rest. He also drew from Professor Balfour the remark that collectors aided the cultivator greatly if they noted, not merely the altitude at which species were found, but also the special conditions under which the plants were growing naturally.

PRIMULAS FROM A GARDEN POINT OF VIEW.

Mr. Craib's paper, a technical one, bringing Sir G. Watts' synopsis up to date, was in the absence of the author, taken as read.

The Rev. W. Wilks read Miss Gertrude Jekyll's paper on "Primulas from a Garden Point of View," which dealt with primroses and polyanthuses in their various colour forms, alpine and border auriculas.

This short paper formed a fitting conclusion to the conference series, because it described how gardens had been and could be beautified with hardy primula species and the host of garden forms now available, especially when these were planted with a free hand, and proper sites were selected for them.

Sir John Llewelyn proposed a vote of thanks to those who had contributed papers, and this was seconded by Mr. R. Wallace, and heartily accorded. A similarly hearty vote was accorded the veteran chairman.

CARNATIONS DUCHESS OF DEVONSHIRE AND FAIRMOUNT.

On referring to the Gardeners' Magazine of March 15, I was interested in Mr. M. Allwood's article, "Perpetual-flowering Carnation Novelties for 1913." While I agree with the writer to a great extent, I must take exception to his criticism on Duchess of Devonshire, and also the optimistic and somewhat inflated character which he gave to Fairmount.

With reference to the former variety, Mr. Allwood is good enough to admit that this deep crimson is of beautiful form. However, he says "it is not quite so free-flowering as some of the varieties." I should be glad to know how Mr. Allwood arrives at this conclusion. How many plants has he grown?

As the raisers and disseminators of Duchess of Devonshire, my firm claims that it is the best all-round crimson carnation for private collections. In my opinion, no crimson variety has yet reached high-water mark of perfection, but it is claimed for the variety that it is free-flowering, and makes a beautiful plant, such as the average private cultivator delights to look upon; and I further state that it would give more flowers over any given period than any other crimson variety in existence.

It would be superfluous to give my own experience in growing the Duchess of Devonshire, but I might say that, with the large number of professional gardeners and amateurs who have grown the variety, it is a great favourite.

Last week I was in the North, and went to see a large private collection of perpetuals in the vicinity of Warrington, where even Mr. Allwood will admit conditions, owing to the chemically-charged air, are not quite ideal. This collection contained a large number of plants of Duchess of Devonshire, and the owners immedately stated that it was the best all-round crimson that he had ever grown.

I could also give numerous other opinions of gardeners who are well up in the carnation world, to say nothing of the constant reference in your columns, and other of the principal gardening papers which report shows. This must prove, by the accounts given, that Duchess of Devonshire has come to stay.

With reference to Fairmount, Mr. Allwood says that the growth is strong and healthy, and that the variety is likely to supersede the popular variety Mikado. My experience in growing Fairmount is limited, as we have only a few hundred plants. However, I have already seen enough of it to be able to say that it is nothing like so free-flowering as Mikado, and, in my opinion, it cannot lay claim to being a healthy grower. In expressing this opinion, I have in my mind stocks that I have seen growing in different parts of the country.

I think that if Mr. Allwood were to try a fresh stock of Mikado, he would very soon alter his opinion of this magnificent forerunner of the mauve varieties. Mikado will outlive Fairmount, and many other mauve-tinted varieties of recent introduction, although it is not by any means a faultless carnation.

C. H. Taudevin.

DECORATIVE DAHLIAS.

What are known as decorative dahlias have come to the front in recent years, and, notwithstanding their having to enter into competition with the extremely popular cactus section, are more largely cultivated year by year. In common with other members of this family considerable diversity is seen both as regards size of flowers and stature, but, without exception, they well deserve the appellation decorative, being capable, under favourable conditions, of producing a gorgeous display and fine effect in the garden. There is much to recommend the bringing together of these plants in substantial masses, such as large isolated beds, stretches of border, groups in the shrubbery, etc.

Here in Bermondsey extensive borders 200 feet by ten feet are planted with ten-week stocks, and among them are arranged solid blocks of dahlias, every section being represented in the most suitable varieties. It is only fair to say that the decorative kinds are second to none; in fact, those groups stand out in conspicuous fashion, and fully demonstrate their value for garden decoration. Further, they require little or no thinning of either growths or flowers, while they possess a strong constitution and stout habit of growth.

It is worthy of note that small plants form large tubers by the end of the season, so that it is possible to work up a big stock from cuttings in the usual manner. It is well known that a number of varieties in other sections fail in this direction, the tubers being little more than enlarged stems the first year. In writing of varieties it must be stated that one or two new introductions are of great merit. Messrs. Cannell and Sons have shown well a new creation, which bears the name of Queen Mary. The blooms are large, with broad florets, and a bright pink shade. Another acquisition is found in Useful, which was raised by Mr. J. T. West, and produces rose-mauve flowers on long and stiff stems.

Too much cannot be said in favour of Kaiserin Augusta Victoria, of spotless purity and wonderfully floriferous habit. It has figured largely in the London parks and gardens for some years, and attains to a height of about three feet. Souvenir de Gustave Doujon is now well known and widely distributed. It forms a capital background plant, with its seven-feet stems, surmounted by orange-red flowers of immense proportions. Messrs. Ware, Lim., have supplied a sport from this variety, a fine flower with white-tipped florets. I procured a few plants of La France last season, and was much impressed with its beauty and colouring, namely, soft rose. In some instances the blooms were tipped with silver. In Brentwood Yellow we have an ideal plant for bedding or front row work. It grows to about two and a-half feet in height, and produces immense flowers of a soft golden colour—a splendid acquisition. Scarcely second to the foregoing is Yellow Colosse, although it flowers less freely in town gardens. The last-named is content with a three-feet stature. Further comment is needless. Attraction, raised by Mr. Turner, is to be recommended, the beauty of its crimson-maroon flowers being enhanced by the presence of rose colouring at the tips of the florets, while the flowers are of great size.

Then we have Loveliness, which is worthy of its name, and must find a place in every garden. Its colouring may be described as an art shade, and what a valuable variety to supply decorative material as cut flowers.

DECORATIVE DAHLIA USEFUL.
Flowers, rose-mauve. Raised by Mr. J. T. West.

Certainly one of the most charming varieties is seen in Jeanne Charmet, in lilac and pink, the basal part being more or less suffused with gold. Built on the same plan as Souvenir de Gustave Doujon are the blooms of Mdlle. Helene Charmet, and, these being pure white, it may well be associated and rub shoulders with it. And yet another is Papa Charmet, with crimped, broad-petalled, crimson-maroon flowers. A group of this variety strikes a rich note.

As a town plant I cannot say much in favour of Madame Van Der Dael, and great is the pity that its beautiful silvery-pink blossoms are not more freely produced so placed. On the other hand, Moda Lumeire is a huge success. Delice, Phenomené, Le Grand Nainton, and Gloire Lyonaise extend the list, and each and all are worth attention, and prominent positions in the garden.

WALTER H. AGGETT.

LATE GRAPES.

Vines in late houses should now be helped forward by a moderate use of fire-heat, early closing, and good syringing twice a day; better results follow the use of a little fire-heat in March and April than double the quantity in September and October. Late grapes enjoy a temperature suitable for muscats, and as soon as the bunches are prominent 58 to 65 degrees at night may be allowed according to the outside temperature, closing with plenty of sun-heat and the usual rise during the day. Another great help at this season is a good mulching of fresh short stable manure with plenty of droppings in it: this not only acts as a stimulant, but affords a never-failing source of atmospheric moisture. Pay careful attention at all times to ventilation; a little should always be allowed at night, as it is an excellent preventive of scalding and disposes of condensed moisture.

F. JORDAN.

SOME GOOD ALPINE FLOWERS.

Convolvulus Soldanella.

A good plant we but seldom see at its best in the rock garden is one of our native flowers, Convolvulus Soldanella, a non-climbing species of the highest beauty. We seem to be too good to it in the garden, and it does not always flower there with the freedom with which it blooms on some of the sand dunes of our coasts, or the shingle which fringes some of our shores. It is a delight to come across it there, and the writer well remembers his disappointment at the result of a search in vain for it on some sand hills where it had been once recorded. It is so beautiful, with its big flowers of pale-purple or pink—large for the size of the plant, which is rarely a foot high. The secret of success is to secure small plants in pots, and to plant them out in almost pure sand, so thoroughly drained that all the surplus water passes away, or to put it in a well-drained moraine. Rich soil is its detestation, and moisture at the roots is its horror.

Coprosma acerosa.

In this New Zealander we have a curious, yet pretty plant, with narrow, pointed leaves, which are nearly evergreen. It is of straggly habit, and looks best when trailing over the rocks. Its main beauty lies in the pretty, oval, blue berries which succeed the insignificant flowers, and very attractive, indeed, do these appear on a good specimen. To see it best the plant should be well up on the rockery, and if it grows too large it should be cut back. In some places it has been found a little tender, and in all parts it ought to have a sunny, sheltered situation, where it is protected by other parts of the rockwork from the northerly winds. It must have a good root run, and should be planted in loam, leaf-soil, and plenty of grit. It is raised from seeds or cuttings.

Sedum cyaneum.

One may go through a good many rock gardens of considerable importance without ever seeing Sedum cyaneum, a species of considerable beauty, and one which has been greatly prized by many connoisseurs. This may be because of its comparative rarity, and its rarity is probably due to its tendency to tenderness in many gardens. This Bluish Stonecrop is a native of Eastern Siberia, and possibly dislikes our wet winters more than sheer cold. We have seen it in some northern gardens, but in most of these it was sheltered from the winter rains by a sheet of glass, under which it proved hardy. The writer knew a keen alpine grower who prized the possession of Sedum cyaneum so greatly that he would never part with any of his plants, or even cuttings—a bit of stinginess not often seen among those who have kindred tastes. Sedum cyaneum is only three or four inches high, and has thick, blunt, entire, opposite leaves and heads of purplish-blue flowers. The name of cyaneum suggests a brighter colour than the flowers really are. It is increased by pieces taken off and rooted in sandy soil. It prefers a gritty loam and sand, and should have a due south aspect.

Mazus pumilio.

The Dwarf Mazus first appealed to the writer a good many years ago from seeing it figured in Wooster's "Alpine Plants," then just published. The desire to own it was soon gratified, and, though one has seen many more showy alpines, yet Mazus pumilio fulfilled all one's expectations. But it was not found very easy to keep in wet winters when on the lower levels of the rock garden, but we discovered that it was necessary either to plant it on a sloping part, or to mulch it well with fine grit in autumn, so as to prevent it from damping off. Some cover their plants with a sheet of glass, raised a little above them, but this is not absolutely necessary, although a good precaution, especially if the mulching is added. This Mazus is a low-growing, creeping plant belonging to the Figworts, and it bears above its wrinkled leaves rather pretty flowers of pale-purple or violet with a white throat. The leaves lie quite flat on the soil. In the moister and shadier parts of the rock garden it requires a soil of very sandy loam with plenty of grit added, and a top-dressing of pure grit, but in sunny exposures it may have loam, leaf-soil, sand, and grit in about equal proportions. S. Arnott.

EXHIBITING AND JUDGING DAHLIAS.

The following is the text of a lecture delivered at the National Dahlia Society's Conference by Mr. C. G. Wyatt, of Salisbury:

The subjects placed in my hands to deal with are "Exhibiting and Judging Dahlias," and thought at first sight they would appear to be of the same character, and are, of course, always intimately connected, I purpose to deal with each separately, in order that our minds may be centred on one point at a time.

There is no shadow of a doubt that by far the greater part of the dahlia enthusiasm we have seen, the large amount of time and money spent, and the thousand pleasant reminiscences in the dahlia world, have been in direct association with the exhibition table and its surroundings, and, although great men among dahlias to-day are seemingly bent on bringing into greater prominence the value of the dahlia as viewed at a distance, perhaps as a plant in its entirety, in other words, for garden decoration, we can not lose sight of the fact that the dahlia is pre-eminently a flower for exhibition, a thing of beauty in every solitary blossom, and, like a charming maiden, her beauty is in her face, and not in the clothes she wears.

Perhaps in the whole realm of floriculture no flower exists which more quickly and more certainly shows the effects of good culture, almost incessant watchfulness, whole-hearted love for its care, its protection, and well-being, than the dahlia.

But I shall be wandering from my subject if I say anything more in regard to that. The old adage says: "First catch your hare, then cook it." Well, if I may say so without disrespect to those models of beauty we have in our minds, I have simply to deal with the cooking after being caught, leaving the forces which brought the flower to be a fit subject for a Royal Court function to other hands.

Before I say anything of the immediate presentation before the eyes of all beholders, I had better deal with the preliminary necessities for showing, of boxes and boards, of tubes and corks, of wires and fixtures, and these must, of course, differ according to the class of flower with which we are dealing. The sizes of boards and stands have been decreed by the National Dahlia Society, so it behoves all new exhibitors to take care that the size and height of their stands conform to the regulations, or they may find the space allotted to them is insufficient, and may, in fact, land their exhibit in that most deplorable of all happenings, disqualification.

Show and fancy dahlias will, of course, be exhibited on boards, and are prepared by the stem being pushed through a hollow cork as far as it will go, until the flower is held erect by it, when pieces from the end of the stem are pushed into the lower end of the cork holding it firmly in place, and the cork can then be fitted into the tube, and all is ready for the exhibition board.

Cactus dahlias, if to be shown on boards are dealt with in the same way. If to be shown in bunches, this will necessitate wire frames to hold them in position, the stems and wire frame being bound up together with raffia and placed in the tube. Pompons and singles are treated in the same way in smaller frames.

I do not intend to dwell longer on the modus operandi of preparing flowers for exhibition. Exhibitors know the method well, and the advice I would give to a would-be exhibitor is to make his way to some important show an hour or two before judging time, go amongst the exhibitors with his eyes open, and ocular demonstration will teach him far more than the most explicit verbal instructions could do, and he will see there is no trick or difficult manipulation needed, but that the whole preparation is simplicity itself.

I could wish it were the fashion amongst exhibitors to keep the flowers farther away from the boards, so that they may present a more natural and a less cramped appearance, but at present there seems to be no intermediate stage between placing the flowers nearly flat on the boards and raising them on long stems in vases, where, if the face of the flower is turned and fixed straight upwards, it seems to have an unnatural stiffness about it, and if, on the other hand, the flower faces downwards, nine-tenths of its beauty is neither seen nor appreciated, for the most admirable part of a dahlia is in the centre of its face, and only a small portion of its beauty lies in its exterior.

As regards the time for cutting dahlias for show, I may say we invariably cut them as soon as possible after daylight appears on the day preceding the show. Immediately after being cut the flowers are carefully carried to a cool shed and placed in stone bottles filled with water; water is plentifully sprinkled on the floor and benches, and here in the cool and the shelter, the work of preparation goes on through the day. Oftener than not the railway journey to the place of exhibition takes place that evening.

Let me advise all exhibitors to keep their eyes on the boxes whenever possible during the journey, and especially on arrival at the terminal station, or before one is aware of it the boxes will be out on the platform, stood on end, or may even be upside down, and when this occurs, unkind thoughts, ruffled tempers, and expressions more forcible than polite are imminent, and it has been said that porters surely miss a money tip and but barely miss a boot tip on such occasions.

But let us hope no untoward incident has occurred, and that the flowers have arrived at their destination in good condition. Now place the boxes in an airy, cool position, but on no account spray them or leave them damp, or they will quickly shed their florets and spoil the chances of a prize.

The first work in the morning will be to select the actual position for each exhibit, then proceed to arrange the flowers, having due regard to colours, placing light and dark ones alternately. Care should be taken that the colours do not clash; purple and mauve shades require special watching in this respect, for if brought into proximity with a scarlet the effect is disastrous. Take care that whites, yellows, and very pale shades are evenly distributed or the stand will have a one-sided, badly-balanced effect. Now be careful to name each flower correctly, and the neater and less conspicuous the name card is the better the flowers will look. Many a good stand is made hideous by badly-written, misspelt names on unsuitable material.

Above all, think more of the exhibit than of the prize, keep a cool head, and centre your whole attention on what you do, or some foolish mistake at the last moment is likely to happen, such as putting two flowers of one variety in a stand, or transposing the positions of two flowers and leaving the original names where they were, so that both flowers are wrongly labelled.

(To be continued.)

SELECT POMPON DAHLIAS.

In writing about these delightful little Dahlias one is not confronted on taking up the pen with the task of differentiating between varieties that are best suited for the production of attractive colour effects in the garden, and those which by reason of their exquisite colouring and perfect modelling are able to render good service on the exhibition stage. Why there is no reason to arrange the pompon dahlias into two distinct groups can be stated in a few words, and these should have the most careful attention from those who are interested in garden management. To be brief, all the finest of the varieties included in the section happily combine an excellent habit, with abundant flower production and blooms closely approaching perfection in form and highly attractive in colour. If it is also stated that the exquisitely formed flowers are carried well above the foliage on erect stems, it will at once be seen that these varieties afford excellent material for indoor decoration. All the varieties are not equally suitable for the supply of cut flowers for decorations, but this is not a consequence of the imperfect development of the blooms or of a weakness of stem. It is simply owing to certain of the colours being less pleasing in rooms than others, the rose-coloured and purple shades, for example. In the garden and on the exhibition stage blooms of these colours are all right, but in the subdued light of the living-room they are dull and unattractive.

To raise and prepare a stock of plants is a very simple matter. Not taking an active part at competitive gatherings beyond assisting in the judging and discussing with my friends the relative merits of varieties new and old, there is not in my case any occasion to consider which of the methods of propagation is the most conducive to the perfect development of the centre of the blooms. My practice has for many years past been to start the roots in shallow boxes partly filled with a mixture of loam, leaf-mould, and sand, and the results have been so satisfactory as to render change unnecessary. The roots are taken out of the store early in March, and placed in a structure in which a temperature of about 55 degrees is maintained. For convenience of potting later on, the tubers are shortened to one-half their length with a sharp knife, the cut being made at right angles. The cut ends are dipped in lime, and the roots are stood in the boxes, without soil, for the cut ends to become dry. At the end of seven or eight days sufficient of the mixture mentioned is filled in about them to reach to the base of the stems.

The first growth on each root is rubbed off when about an inch in length, and this check will cause other buds to shoot into growth. Later on, when the shoots are about two inches in length, they are reduced to two or three each by the removal of the most weakly. The next step is to put the roots into six-inch pots, using a compost consisting of loam, well-decayed manure, and coarse silver sand. They are kept close for a few days, and then the ventilation is gradually increased to harden the new growth. When this has been accomplished, the dahlias are removed to an unheated frame, where they remain until bedded out. In the meantime, they receive free ventilation during the day and efficient protection from frost at night. Plants now growing in small pots will, if they are at once shifted into others five or six inches in diameter, a rich compost being used, be in splendid condition for bedding out five or six weeks hence.

DECORATIVE DAHLIA QUEEN MARY.
Flowers bright pink.

Turning from the plants to the beds and borders in which they are to be grown, it should be first stated that previous to planting the soil should undergo a thorough preparation. In other words, a rather liberal dressing of manure should be applied and the ground be dug over to a depth of not less than twelve inches, the manure being well mixed with the soil in the process. In common with other dahlias the pompons require a soil for their successful cultivation that is moderately rich, but not, as some writers on these flowers would imply, reeking with manure. The big holes filled with manure which are so frequently recommended are not only unnecessary, but most undesirable. When arranged in beds wholly devoted to them, plants prepared as here advised should be put about thirty inches apart each way. Those on the other hand, that are kept in three-inch pots will have ample room if eighteen inches apart, and if with single stems and in five-inch pots put them two feet apart. Pompon dahlias are useful also for brightening up the mixed flower border late in the summer, and in my garden those used for this purpose are planted about six feet apart along the front line. The best time for planting is the end of May, and in planting the soil should be pressed firmly about the roots.

The following varieties are of high quality, and afford a wide range of colour, namely, Annie Holton, crimson, the florets tipped with white; Captain Boyton, maroon-crimson, one of the very best of the dark varieties; Daisy, amber and salmon, distinct and attractive; Glow, coral-red, very pleasing; Douglas, maroon, shaded crimson; Edith Bryant, pale yellow, margined with crimson, an effective combination of colour; Florence, lilac colour; H. E. Searle, rich orange; Ideal, clear yellow; Mars, brilliant scarlet; Montagne Wootten, white, margined with lake; Nerissa, soft rose-pink; Queen of Whites, pure white, very fine; San Toy, white, margined with carmine; Tommy Keith, cardinal-red, tipped white; and Whisper, clear yellow, margined with bronze. White Aster is an exception to the foregoing inasmuch as the flowers are not of exhibition form. They are, however, light and elegant and of quite exceptional value for floral arrangements. In the garden they are most effective, and the variety may be described as one of the most useful of the white pompon dahlias for beds and borders. J. R. S.

CYPRIPEDIUM SPECTABILE.

For a cool situation in a half-shady spot there is scarcely anything more beautiful among hardy flowers than a good group of Cypripedium spectabile. It is the finest of the North American species, and the showiest of the hardy orchids, having large flowers of a blush-white shade, overlaid with a lovely rose tint, these being carried on tall stems that vary from eighteen inches to thirty inches, according to the situation.

It succeeds best in a compost of peat and loam, in equal parts, and must not suffer from lack of moisture during the growing period, although in the winter it enjoys rather drier conditions. The best planting season is in spring, when the increasing sunheat begins to make the soil warmer, as this ensures a full season in which the plants become established. This cypripedium is very effective when intergrouped with Gillenia trifoliata and the foreground planted with dodecatheons and trilliums, all of which succeed under similar conditions. Thomas Smith.

Coombe Court Gardens.

THE ECONOMICS OF BRITISH WILD FLOWERS.

There are undoubtedly numbers of people who believe the value of plants to man begins and ends with the vegetables in the garden, and the fruit in the orchard.

But there are many British wild plants that are of equally as much value to the manufacturer as are tea, coffee, cotton, and the innumerable other valuable plants that grow abroad in the hotter regions of the earth, e.g., rubber.

In England we can number plants that produce gums, resins, and turpentine. Quite a number yield oils. Then, every colour of dye is furnished by different well-known British plants. Even marking-ink can be made from oak, and many other plants beside the elm serve for tanning leather. Everyone knows how stringy a nettle is, who has to root one up, and many other plants yield fibres or bast, while flax has been grown for linen from a time wrapt in obscurity before the Romans came.

Whole books might be written upon the question of plants suitable for use as drugs. Even in the time of Bacon superstition reigned supreme in this realm of knowledge, for by a crude kind of logic human symptoms were read into plant peculiarities, and the two were regarded as connected beneficially for the patient, with ludicrous results, such as the necessity of using yellow juices to cure jaundice. But in spite of this ignorance a fairly large number of plants have important principles, which are efficacious and of value to the physician, some being astringent, others, as henbane, narcotic, or sedative as bittersweet. The salts of lemon, so useful for removing ink, can be prepared from common sorrel. Doubtless many of the vagrants who are to be seen frequently with a pipe in their mouth know that coltsfoot leaves yield a sort of tobacco. Every summer brings with it, not only the scent of new-mown hay and roses, but a host of other delightful perfumes. Valuable ointments are also to be derived from various plants, as well as soaps.

The plants useful for edible purposes, either as fodder, cereals, bird-seed, fruit, to make jelly from, yielding tubers, spices, flavouring materials, sago, sugar, honey (by help of the bees), the score or more vegetables, old-fashioned pot-herbs, salads, pickles, confectionery, beer, wine, spirits, tea (of a sort, produced by holly), sloe, rosebay, tansy, horehound, coffee, and jalep, are probably better known to most people than any other group of useful plants.

We are but just realising the necessity of replacing our valuable timber supplies as they are used up, by the planting of young trees in the place of full-grown timber, and it is probable that few people know the peculiar use to which each of our trees may be put, for each is more suitable for one purpose than some others. Field maple is adapted for making furniture and bowls, cups, and similar light articles. Rakes are made from the wood of the sloe. Pipes (and cabinet work generally) are made of cherry wood. The wood of the bird cherry is very prettily veined, and used for the handles of tools. Yokes and the cogs of mill wheels have been made largely from the white beam tree. Mountain ash is very hard, and takes a good polish.

Hawthorn is equally hard wood. From the cornel spear shafts were made, also bows, cog wheels, skewers used by butchers, and ramrods. The ash is another hard wood used for making agricultural implements, packing cases, hop poles, walking sticks, hoops, and baskets. The keels of ships used to be made from elm, but steel has now replaced the wood almost entirely except for fishing boats. The birch is another tree which supplies the agriculturist with handles for implements. Piles under water are made of alder, which stands inundation well, and turnery bowls and kneading troughs are made from it as well. Posts and rails are made of oak, and beams in old buildings are usually oaken also. Furniture, screws, piles, and sabots are made out of beech. Walking sticks, crates, and hurdles are made of hazel wood. Hornbeam supplies material for agricultural implements, mill works, and yokes.

The willow and osier are used as supports of vines, for wickerwork, panniers, and chairs. Ships were largely constructed once from Scotch fir, and tar, pitch, and turpentine are derived from it. Small articles are constructed of juniper wood. Bows were made of yew wood. Fine-grained woods were used in the early days of wood engraving, such as lime, box, and pear, and mathematical instruments also are made of boxwood.

Inlaid work, such as Tunbridge ware, is made from holly. For turning sycamore is best, and it is useful as a veneer. Traveller's joy has been used in place of willows for basket work. Broom and ling are employed for thatching in some districts. Besoms are made from the broom, ling, birch, and butcher's broom. Skewers and toothpicks are made from the spindle tree. Gorse and sweet gale, in addition to timber trees, are used as fuel or firewood. For drawing, the spindle tree yields a good charcoal, and for gunpowder, buckthorn, field maple, cornel, alder, beech, and hazel are employed.

Miscellaneous, indeed, are the uses of plants, and whilst numbers are used as garden flowers, many more are fitted for the purpose. Some serve as ornamental shrubs, mistletoe having a unique use at Christmas time. Fuller's teasel did duty, before the stocking machines came into use, for carding wool. Rush bottoms of chairs are made from rushes. Rennet is derived from lady's bedstraw and butterwort (formerly). Soda is procured from sea blite and salt wort, both maritime plants. Rushes were used in the old rush-lights, and reed mace has served for flashing the lights of fireworks, and, with the bulrush, for making casks watertight. Grass-wrack is used for packing glass, cotton grass for stuffing mattresses and for wicks.

To protect the East Coast (and other parts) from denudation sedges and grasses have been planted, as well as shrubs, to encourage the sand which accumulates to become permanently fixed.

A. R. Horwood.

Leicester Museum.

Cedronella triphylla (syn. Dracocephalum canariense).—Plants with sweet-scented foliage are appreciated by most people, but for some reason or other this good old member of the Labiate family has almost dropped out of cultivation. It was commonly known as the Balm of Gilead, and was met with in most greenhouses, a few sprays mostly forming part of the old-fashioned nosegay. The flowers are not showy, but the leaves, when gently rubbed, give off a very pleasing fragrance. It is a plant of half-shrubby character, and may be readily increased from cuttings of the young shoots. It is a native of the Canary Islands, and introduced in 1697.—S. W.

CORDON MELONS.

There are important advantages to be derived from the training of melons upon the cordon principle even by cultivators who have no other convenience than the ordinary frame for their culture. Of the advantages to be gained from this system over that which may be termed fan training, that may be considered, there is the earlier production of fruits, and the consequent saving of labour and fuel, together with the benefit to be derived from being able to clear away the plants, and thereby make room, at an earlier date, for succession crops. Moreover, there is the possibility of growing greater variety in a given space than can otherwise be done.

The best and most convenient kind of structure in which to grow cordon melons are lean-to or hip-roofed houses or pits with south aspects. There is here an inexpensively-built pit of this description that answers its purpose admirably, from which we usually, without difficulty, gather the first crop of fruit during the last week of April or early in May, and the latest in November. This pit is a lean-to, ten feet in width, with a sunken path at the back, and a bed heated with pipes in the front, with its surface on a level with the outside ground. The pit has no front glass, but air is admitted by ventilators placed in the front wall, close to the surface hot-water pipes. This structure is specially arranged, not as an ideal one, but merely in order to show that melons can be produced in fine condition throughout the season by moderate means.

Houses or pits of this kind should, of course, be provided with trellises, that are placed about fifteen inches from the glass, and the plants should be arranged along the front of the house upon the bed. If the melons are planted out, a low ridge, or hillocks, of compost should be provided for them, to which top-dressings of fresh compost could be added at suitable intervals in order to meet the plants' requirements. Should pot culture be preferred the pots must be firmly plunged in their positions. The plants may be raised in the ordinary manner singly in two and a-half inch pots, and if they are to be grown as single cordons, which is an excellent method to adopt, and certainly the best if ripe fruit is required at the earliest possible date, they should be planted out from their seed pots at two feet apart, and trained upon their trellis until they have reached the desired height, before being stopped.

If double cordons are preferred (by which method fewer plants for a given space are required, and each one, if planted out, has increased rooting space devoted to it—conditions of doubtful advantage) the plants should be placed four feet apart, be stopped as soon as they have developed four rough leaves, and each have two growths trained from it. The principal growths should be secured to the trellis at two feet asunder, have their points stopped, as in the case advised for single cordons, their laterals thinned and stopped, in the case of those producing the fruit, at one leaf beyond the fruit. Three fruits to a single cordon, and five or six fruits to a double cordon, provided fruit of excellent quality is desired, are sufficient for a crop, while for exhibition purposes it is advisable to allow one fruit only to each single cordon plant.

In the cultivation of cordon melons in ordinary unheated pits or frames it is a good plan to form a ridge of compost throughout the length of the frame, narrower at the back than the front, upon a carefully-prepared bed of fermenting material. Double cordon plants should be used, and be planted two feet apart, which is invariably equivalent to two plants to a light. The stems of each plant should be trained, one directly to the front and the other to the back, and be stopped when they reach the sides of the pit. By supporting the stems with bricks, or with something of that kind, so that they are kept from coming into contact with the bed, there will be less likelihood of canker, and if the laterals are raised upon small forked sticks the blossoms will be kept dry, and the fruits will the more readily set.

T. COOMBER.

The Hendre Gardens.

ŒNOTHERA TARAXACIFOLIA.

The dandelion-leaved evening primrose is not very much grown, though it is by no means the least beautiful of the family. It is a trailer, somewhat similar in growth to Œ. macrocarpa, but with larger and more vigorous leafage, while its enormous pure white flowers are very conspicuous in the twilight of the summer evenings, and not altogether devoid of beauty the following morning, when they become pink. A bank, or a piece of rockwork, clothed with this œnothera is very effective, yielding a succession of blossom from midsummer to Michaelmas.

It has the advantage of doing well in damp and shady places—situations to which few purely summer-flowering plants are partial. It can also be used as a surfacing plant between tall bedding plants, such as fuchsias, balsams, zinnias, etc., or along the front of mixed borders, with a few short sticks to assist it to cover any vacant or thin places. It does not, however, do well amongst greedy perennials, as it is a lover of good things in the way of food and moisture, though an excess of these, accompanied by too much shade, will result in gross growth and too little blossom.

In light soils this œnothera may be regarded as a perennial, though not a long-lived one, and, in general, it is best treated as a biennial, or even as an annual, for if sown in February in heat and pricked off into pots it may be had in flower by the end of June, plants rased in this way growing very vigorously, and producing enormous blossoms. Or it may be raised in July, and pricked out on a nursery bed, care being taken not to move the plants late in the autumn, as this is fatal to their standing the winter, the early spring being a better time for the operation. Those with wet soils would do better to keep plants in sixties through the winter in a frame, as not many plants are often wanted, a half-dozen spreading over a good deal of ground by the latter part of the summer.

ALGER PETTS.

DAFFODILS IN THE TURF.

For the spring garden the varied forms of the narcissus are invaluable, not alone for the borders, but for naturalising in the grass, the latter method, now so largely followed, not only creating a most pleasing effect, but also being, in many cases, better suited to the requirements of some varieties than culture in tilled ground. As an instance of this two kinds may be specially cited, namely, the Tenby daffodil (N. obvallaris) and N. pallidus præcox, both of which generally succeed better in the grass than in worked ground. Several of the smaller and less vigorous kinds are well adapted for the rock garden, such as the tiny N. minimus, that in the south-west often expands its little yellow trumpets before the end of January in company with the snowdrops; the varied forms of the hoop-petticoat daffodils (N. corbularia), golden, sulphur, and white, the variety of N. triandrus known as Angel's Tears, and N. t. pulchellus, though the latter, being of stronger constitution, succeeds equally well in the border, as well as the quaintly-formed N. cyclamineus, which delights in a moist root-run.

Many of the golden and bicolor varieties of the trumpet daffodil are well suited for naturalising in the grass, such as the deep yellow Golden Spur, N. maximus, Emperor, and Queen of Spain, an attractive variety, bearing clear yellow flowers of peculiarly distinct form, the trumpets lacking the flanged rim possessed by all other varieties of this section. Of bicolors Horsfieldi, Empress, and grandis form a fine trio, and when planted in quantity have a striking effect. They are very similar in size and colour, and, attaining perfection in the order in which their names are given, extend their display over a considerable period. The old double daffodil also succeeds well in the grass, though it lacks the grace of form of the single varieties.

Sir Watkin is the most vigorous of the incomparabilis section, and is well fitted for naturalisation, while many of the numerous varieties of the same class, though of less robust growth, make themselves equally at home. The star daffodils (Leedsi) are particularly graceful and delicate, with their narrow cream-white petals and slender stems, and never reveal their attractions so fully as when growing on a grassy slope, while the Poet's narcissus, when planted in thousands, creates one of the loveliest spring pictures imaginable.

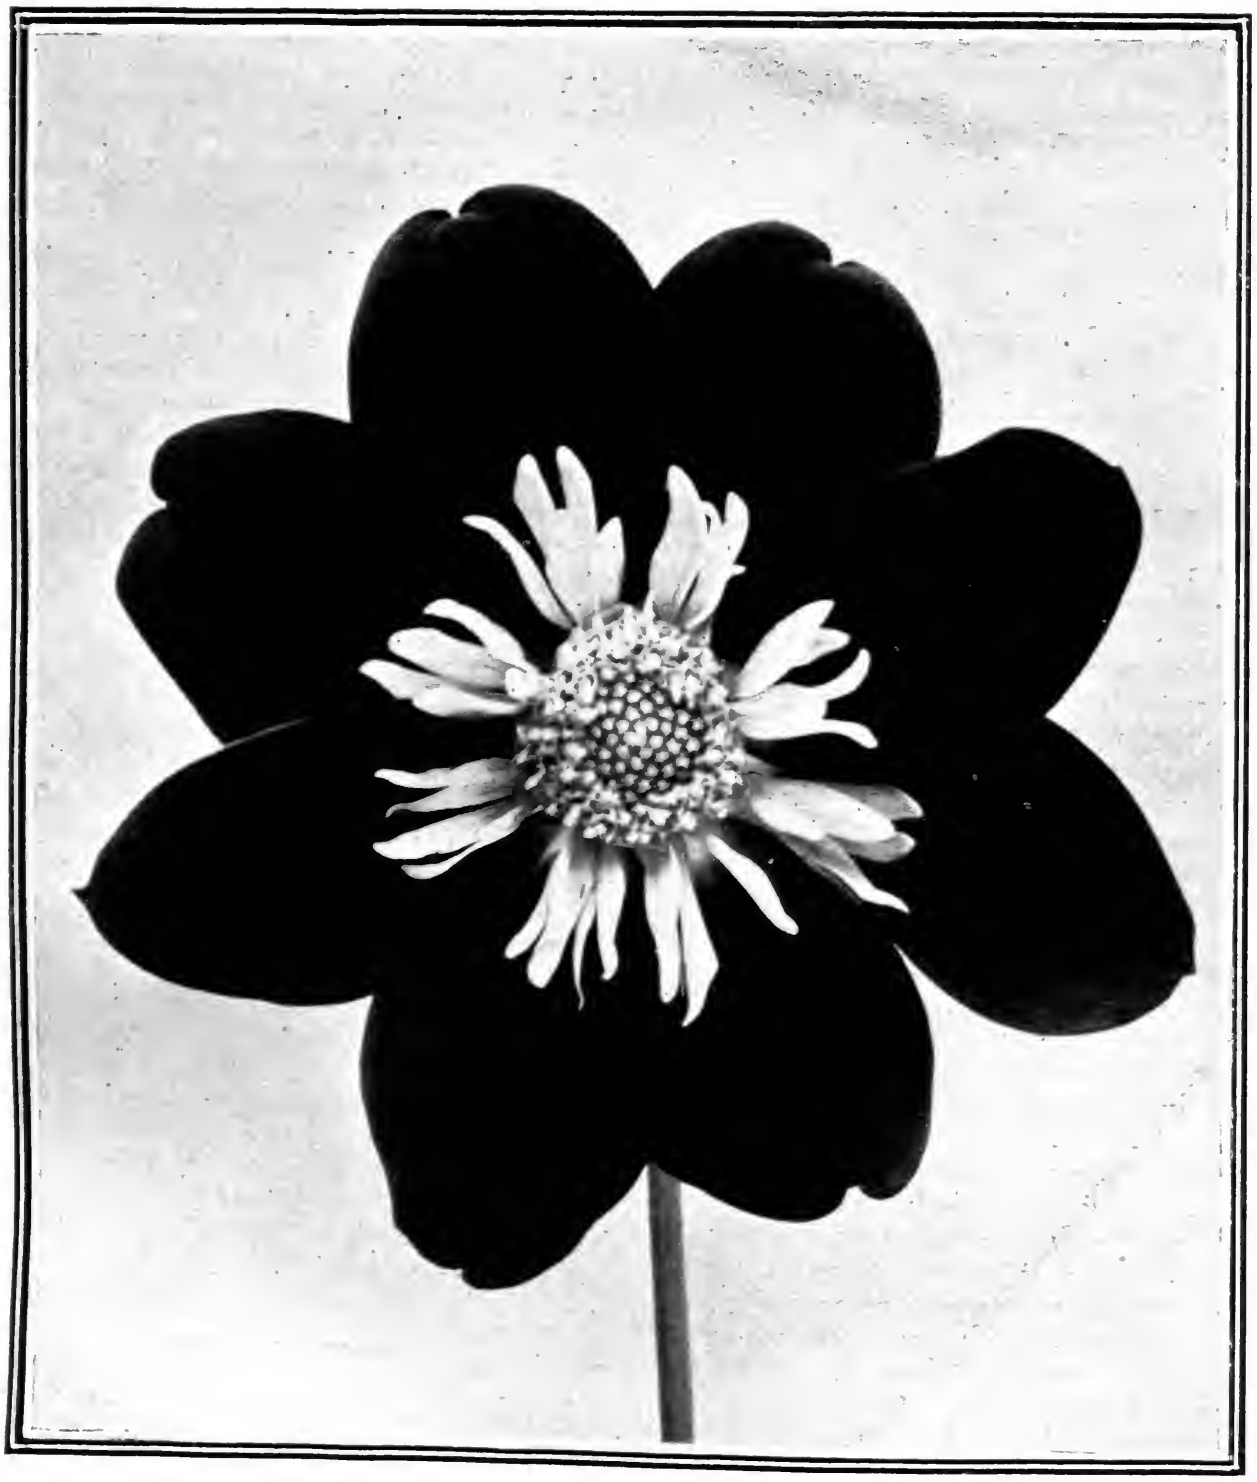
WYNDHAM FITZHERBERT.

Azalea pontica for Forcing.—Though Azalea mollis is extensively employed for forcing, almost to the exclusion of the other kinds, some of the forms of Azalea pontica can be well recommended, as they possess a wider range of colour, are less formal in growth, and their blossoms have a very pleasing fragrance, which, though not powerful, is at the same time very noticeable under glass.—T.

Golden-leaved Caladiums.—The first of the golden-leaved caladiums were raised at Chiswick somewhere about forty years ago, and at once aroused attention by reason of their distinctness from any of the other varieties then in cultivation. They are particularly bright and attractive in the spring just as the young leaves unfold themselves. In constitution these golden-leaved varieties are less vigorous than most of the others, and, though most of them are old kinds, they cannot be regarded as common. Among the earlier varieties are Princess of Wales, Princess of Teck, and Princess Royal; while more recent varieties are Golden King and Golden Queen.—S. W.

THE BEST COLLARETTE DAHLIAS.

There is abundant evidence that the dahlia is rising from the obscure position it has held in our gardens as a decorative plant, and during the coming summer thousands will be planted in beds, borders, boxes, tubs, etc., not with the single idea of growing them for exhibition but with the sole object of producing a brilliant display of flowers to "liven up" the herbaceous borders in the autumn months. garden decoration, in the ordinary sense of the word, and they are equally suitable for colour schemes, and can be planted without presenting that bizarre effect so often associated with dahlias. Their merits are, chiefly, their dwarf, sturdy habit, their floriferousness, and their early-flowering popensities, while their cultural requirements are exceedingly simple. A well-cultivated soil is essential, and plenty of water



COLLARETTE DAHLIA PRINCESS LOUISE.

Flowers, deep crimson, with yellow "collar"; raised by Messrs. Dobbie and Co., Edinburgh.

This, too, has been brought about by articles that have appeared in the Gardeners' Magazine, by the Dahlia Conference held last February, and the appearance of a quite new dahlia book; all these items have served their purpose, in arousing public interest to such an extent that garden lovers begin to wonder how it is they have neglected the dahlia so long as a garden decorative plant.

Those behind the scenes, i.e., the producers of the plants for trade purposes, are fully cognisant of the coming demand, and are preparing to meet it by raising increasing numbers of the sections they think will be most wanted, and of these the Collarette section will not be the least, for the varieties are admirably adapted for during a dry spell; then, with proper staking and tying, and the constant removal of the seed pods, we have their requirements in a nutshell. Disbudding, or even thinning out, are unnecessary items, and are best left alone, for this section is not improved by the production of large, coarse flowers. Neither is elaborate feeding required, as it only tends to produce huge succulent plants, without any corresponding increase in the number of blossoms.

Although the section has only been brought to the notice of the public since the year 1910, it has apparently made rapid strides in their estimation, and already there are something like eighty varieties in commerce—many too much like, and others that are neither a credit to the section or likely to increase the popularity of it as a garden plant. Most of the early forms produced gave shades of red or crimson, but it is pleasing to note that our own raisers are now turning their attention to the production of lighter shades and softer colours, so that we can look forward for almost any hue during the next few years.

In recommending the following varieties I have selected those that produce the finest effect in the garden, regardless of the actual form of the flower: Betty, rosy-pink, with a paler collar; Corbeille de Feu, bright terra-cotta, yellow collar, one of the best for the garden, but rarely seen at shows, as it is a bad traveller; Diamant, velvety-violet, collar light rose; Diadem, rosy-pink, white collar; Exposition de Lyon, rosy-red; Maurice Rivoire, crimson, collar white, does not exceed thirty inches in height; General de Louis, orange-scarlet, gold collar; Henri Farman, yellow, blotched red, collar cream; Leitstern, dark crimson, collar white; Madame Poirier, bluish-violet, collar white, a distinct colour in dahlias; Meteor, dark crimson, edged and tipped gold, collar cream, flowers rather thin, but very free; Prince de Venosa, rich crimson, shaded majenta, collar white; Ville de Schildt, orange, collar yellow; Madame R. Crozy, pink, collar white; Souvenir de Bernadeau, old rose, collar cream. I have only included those varieties that are self-coloured, though many fancies are beautiful.

Coming to the newer varieties which I consider worthy of note, and trial, there are Dainty, a very soft pink with a pale lemon collar; Simplicity, white, tinged pink, collar white; Lotus, white, shaded slightly with red, collar white (these three varieties are a valuable addition to the section, which has hitherto been confined to the darker shades of colour); Princess Louise, deep crimson, collar yellow (see illustration); Balmoral, bright puce, collar white, striped rose; and Holyrood, rich ruby, tipped gold, collar yellow. The last six varieties I can only judge by the flowers as exhibited, but they are all distinct, and should form good additions to any collection, however large.

Chingford. J. B. Riding.

RONDELETIA CORDATA.

There are many plants commonly grown in pots that, were it possible to plant them out in a prepared bed in the greenhouse would be seen to much greater advantage. Such a plant is this rondeletia, an evergreen native of South America. With several other interesting shrubs of a tender nature, it is planted out in a bed in the Kew greenhouse, and under these conditions it is doing remarkably well. It is now a fine bush over 6ft. in height, the shoots being clothed with stout, firm leaves, the largest of which are about six inches long, and about half as much in width. The flowers are freely borne in clusters, somewhat suggestive of those of the laurustinus. In the bud state they are deep pink, but when fully expanded of a blush tint, with a yellowish centre. In every way it is a very desirable greenhouse shrub. Flowering examples of the nearly allied Rondeletia amœna were noted at the meeting of the Royal Horticultural Society on March 18. Other well-known kinds are R. gratissima and R. speciosa, this last being at one time a favourite plant for growing into specimens for exhibition purposes.

W.

PHORMIUM TENAX.

The handsome New Zealand flax is very largely grown in the south-west, where in most seasons it flowers abundantly. The variegated form is also common, and attains large dimensions, one splendid specimen, which is growing on a sloping lawn, producing leaves exceeding 7ft. in length, while its bloom spikes, of which it bore twenty during the summer of 1912, reached a height of over 10ft. The variegated form has been found to be hardier than the green-leaved type, and is such a striking plant that it should be far more widely grown.

One drawback to the variegated form, however, is that in deep, rich soil, where it grows with great luxuriance, it often partially, and in some cases almost entirely, loses its variegation after it has assumed its fullest proportions. In the instance above mentioned there is but slight indications of variegation observable in the foliage, though at the time of planting this was most distinct. In poor soils the variegation appears to be more persistent, but this is generally the case with most variegated plants, which retain their character best when not too highly nourished with manurial matter.

Phormiums are far more hardy than is generally supposed. Plants have grown in the open, unprotected, at Dunrobin for many years. They are within 150 yards of high-water mark, and are sheltered on the north and east by trees and rising ground. Some winters have been exceptionally severe, snow on one occasion lying for nearly four months, and the temperature showing from 15 to 19 degrees of frost, with ice over a foot deep.

There are several forms of Phormium tenax. One variety has pale green recurving leaves, and is not very hardy, and is not a free flowerer except in the warmest of soils and in sheltered sites. A better form is the erect-growing, glaucous-leaved variety, which is hardy and free-flowering, and is the most suitable one for most gardens, especially in cold localities. The best-known forms are Phormium tenax, the type; P. tenax variegatum, with yellow, striped foliage; P. tenax, Powerscourt variety; P. tenax atropurpureum, with maroon-purple leaves; P. tenax Veitchi, which has also a variegated form; and P. tenax Colensoi, a small-growing plant, of which there is a variegated form that is tender. Phormiums are so bold and distinct in the open air that they are as well worthy of careful attention as are the yuccas, cordylines, bamboos, and some other of the plants of a sub-tropical character.

In the warmer districts phormiums succeed excellently if planted at the waterside. Grown in clumps in rich, deep soil, on the margins of ponds, where the roots have free access to the water, the New Zealand flax grows freely and gives a tropical aspect to the landscape which few other plants can excel. When the leaves are ripe they are most useful for tying, if they are split into very narrow strips, as they are unbreakable and, being green, are not unsightly. The leaves last for a long time when cut, and are useful in an arrangement with pampas grass, tritomas, or gladiolus. The forms now under cultivation are probably only seminal varieties. Seedlings raised from the variegated-leaved forms generally have green leaves, and of those raised from atro-purpureum, although a few are as dark as their parent, many more are of a light green. Seeds of Phormium tenax ripened in Europe will retain their vitality for at least six or eight months. From seeds of the type sown last year every plant is growing, and seeds of P. Colensoi have given equally satisfactory results.

WYNDHAM FITZHERBERT.

Kingswear.

SPECIMEN PHORMIUM TENAX AND CHAMÆROPS FORTUNEI
In the garden of Dr. Lewis, Torquay.

REHMANNIA KEWENSIS.

Although Rehmannia angulata has not been grown in this country for many years it is now a universal favourite for greenhouse decoration. Between it and the dwarf-growing, light-coloured R. Henryi a hybrid has been raised, known as R. Bricoei. It has not, however, caught on to any great extent: but R. kewensis, which was raised at Kew, promises to be as much appreciated as the typical R. angulata itself. From the latter the newcomer differs in several flowering shoots being pushed up from the base of the plant, which is well furnished with foliage. The flowers are large, and yellowish-blush, with a dark crimson blotch in the interior of the upper segments. Probably, from the fact of their being seedlings, there is a certain amount of individual variation in the different plants, but all are striking, and in every one the crimson blotch forms a dominant feature, especially at a little distance, as it stands out so markedly from the rest of the flower. At present this Rehmannia does not appear to be in commerce. There was an admirable illustration of this newcomer in the GARDENERS' MAGAZINE of June 29, 1912. S.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CYPRIPEDIUMS.—The late winter and early spring-flowering cypripediums have now passed out of flower, and should be repotted if that be necessary. They will be producing new roots, and if fresh potting compost is afforded now these quickly get hold of the material and become re-established before the hot summer season arrives. For all the plain-leaved section we find that a compost consisting of about two parts fibrous loam to one of peat and chopped sphagnum moss, with sufficient broken crocks and sand added to render the compost porous, is the most suitable. For the variegated or tesselated leaved section, half the compost should consist of peat. The hybrids having C. bellatulum or C. niveum as one of the parents are among the most beautiful of all cypripediums, and it is unfortunate that many growers find difficulty in their cultivation, and are discouraged by unsatisfactory results. There can be no doubt but that situations in which plants have to be grown make a great deal of difference. In a pure country atmosphere there is little difficulty, and in such lovely kinds as C. Venus, C. Boltoni, C. Angela, C. Antigone, C. Wm. Lloyd, C. Chapmani, C. F. K. Sander, C. Lowiebel, C. Schofieldianum, C. Dom Carlos, etc., we have orchids worthy of all consideration that can be afforded them in every collection. We find it best in dealing with this section to attend to repotting immediately the plants pass out of flower. The pots used are well drained with lime rubble and crocks, to about two-thirds their depth. The plants are in most cases surface rooting, and no great depth of potting compost is necessary, and as a rule the roots pass down close to the sides of the pots in preference to penetrating the potting compost. The material we find most useful is two parts turfy loam to one of peat, with a little sphagnum moss added. Careful watering is necessary after repotting, but as soon as the plants have become re-established they require an abundance of root moisture during their season of growth. They must be kept carefully shaded from strong light at all seasons. Some kinds are more sensitive to light than others, but the whole of them soon show the effects of strong light by becoming yellow, and this must be carefully avoided. The atmosphere about the plants must at all seasons be reasonably humid, and frequent dampings among the pots is essential immediately after repotting.

CYPRIPEDIUM FAIRIEANUM we find does better among the warmest section during the growing season, and should be removed to the intermediate section in the autumn as soon after they show their flowers as possible. The cooler treatment we find retards growth, and does not produce flowers of the finest quality. The hybrids of C. Fairieanum are now so numerous that space does not permit of their enumeration. Practically all sections of the genus have been used in hybridisation since the reintroduction of C. Fairieanum, and consequently we have hybrids flowering at all seasons of the year. In most cases these are best treated in the warm intermediate house.—H. J. Chapman, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

VIOLETS.—Attention must now be given to the plants which will be required for blooming next season. Although under favourable conditions young plants may be propagated readily from the old ones by division of the roots at the present time, the best method of propagation is that of inserting cuttings in the autumn. If the cuttings were inserted closely together in a cold frame in a sandy compost they will now be ready for planting out in a well-prepared border facing north or east. The soil should have been dug several weeks back, and a good quantity of well-rotted cow dung should have been used in the process. The surface of the soil must now be broken up with a fork, and raked over with a fine rake. Put the single varieties out about a foot apart; the double kinds may be given a little less room. Planting must be done firmly. Red spider is a persistent enemy of the violet, and is a frequent cause of failure. Therefore special precautions must be taken to combat this enemy. Light dustings of soot at frequent intervals is not only distasteful to this pest, but it is also a valuable stimulant to the growth of the plants. Violets require plenty of moisture at the roots, and during dry spells of weather they must be sprayed twice daily.

CYCLAMEN.—The young plants may now be given a slightly lower temperature. A position near to the glass in a shallow, heated pit will suit them until the weather becomes warm enough to place them in cold frames. The pots must be stood on a cool, moist base. Repot when they are sufficiently well rooted, keeping the corms above the surface of the soil; five-inch pots are usually large enough in which to flower one-year-old plants. A compost consisting of good fibrous loam (with the finer particles sifted out), leaf-soil, dried sheep dung, with a little sharp sand and finely broken old bricks to keep the whole porous, will suit them. Unless the plants have recently been repotted air may be admitted more freely now than formerly, but cold draughts must be avoided. Always syringe the foliage with rain water twice a day, and keep the atmosphere moist by frequently damping the surroundings. Never apply water to the roots until it is needed. Greenfly must be watched for, and, should they be present on the leaves, lightly fumigate with a nicotine compound. Old plants which are maturing seeds must be well supplied with moisture at the roots. Keep them growing on a shelf near the glass exposed to the sun.—E. Harriss, Lockinge Gardens.

HARDY FRUITS.

FIGS.—As these are usually supplied in pots, planting may be done with advantage much later than would be the case if the trees had to be lifted from the open. Figs thrive in some parts, and produce very heavy crops of luscious fruits annually with very little care and attention, especially where the soil is resting on chalk, and the position is somewhat sheltered from the north and east winds, but in the less favourable parts the trees need to be grown on a good south wall, and the roots restricted to a space of three to four feet wide, and as much in length, by slabs or bricks, and the depth of the border should be about 2ft. 6in. Use abundant drainage, over which place turves, grass side downward, and fill in with good loam, rather light, and old mortar rubble and wood ashes. This mixture will need to be made firm, so that the roots may have something to grip. Fig trees require plenty of head room for extension of the branches, and to induce short-jointed wood that will ripen thoroughly by the end of the growing season, otherwise the results will be unsatisfactory. Trees that may have been left unpruned till late, a method usually practised in the colder parts, where protection is afforded in the winter months, will need to be taken in hand without further delay. Secure all the main branches in the required positions, and then fill in with the rest, but do not attempt to shorten the leaders, as it is from these that the fruits are produced.

ALPINE STRAWBERRIES.—Plants that were raised from seeds sown in February should be carefully attended to as regards pricking them off in boxes, and encouraging them to grow and become sturdy for putting out by the first or second week in May. They should be given good soil and a light position in moderate warmth, near the glass; much harm may be done by over-watering during the early stages of growth.

PERPETUAL FRUITING STRAWBERRIES.—St. Joseph, St. Antoine de Padoue, etc., put out for the production of a late crop will need to be kept clear of weeds, and some of the earliest bloom will have to be removed to allow others to spring up for the late autumn supply. These, like the early and mid-season strawberries, require plenty of space, rich soil, and firm planting. During the hot weather good soakings of water will assist both the crop and plants, and should the foliage become infested with red spider thoroughly syringe the under side of the leaves a few times with clear water.

FRUIT PROSPECTS.—There is an abundance of apple-blossom buds, and plums and peaches are flowering well, but pears are rather patchy. Trees that bore heavily last year, although well fed at the roots, are showing the fewest flowers. Attend well to all late planted or severely root-pruned trees, and should the weather set in dry, do not let them suffer from want of moisture. Keep the large branches well syringed in sunny weather until fresh growths and roots have formed.—H. Markham, Wrotham Park Gardens.

THE KITCHEN GARDEN.

VEGETABLE MARROWS.—To provide plants for the main crop, seeds may be sown forthwith. Sow them singly in 3½in. pots, and place in gentle heat; when germination has taken place remove the young plants to a cool frame, and gradually harden off ready for planting out. The early sown plants put out in heated pits or on hotbeds in frames will need constant attention as regards thinning and regulating the growths, airing, watering, etc. It is advisable to set the flowers in the same way as melons, and during this period the atmosphere of the pit should be kept rather dry.

ONIONS.—Seedlings raised under glass for the production of very large bulbs may be planted out in showery weather, taking great care in lifting them from boxes not to damage the roots. The rows may be fifteen inches apart, and the plants twelve inches apart in the rows. Plant firmly, keeping the roots as near the surface as possible. During dry weather an occasional sprinkling of water should be afforded.

PEAS.—Sowings of main crop varieties should be made according to requirements; the seeds should be sown in well-prepared trenches as advised in previous notes on peas. There should be no delay in staking the rows as soon as the young plants are well through the ground. Where protection is needed against the ravages of sparrows, stout black thread stretched over the rows on short sticks will be found an efficient safeguard.

NEW ZEALAND SPINACH.—On light soils where it is a difficult matter to keep up a constant supply of the ordinary summer spinach, the New Zealand spinach makes an excellent substitute. It may either be sown where it is intended to grow, which should be on a warm, sunny border, or raised under glass in boxes and transplanted when of sufficient size. Sowings should be made of chervil, borage, chicory, marjoram, radishes, lettuce, spinach, and turnips.

BRUSSELS SPROUTS.—The young plants from the early sowing, after being duly hardened off, should be planted on well-manured ground. Set them two feet apart in the row, and allow the same distance between the rows. The ground should be made firm prior to planting.—W. Messenger, Woolverstone Park Gardens.

MODERN GLASSHOUSES

as supplied by MESSENGER and CO., Ltd., are made of the best materials, and only capable and reliable workmen are employed in the erection thereof.

The following letter was recently received by us on the completion of a contract for a well-known Member of Parliament.

February, 1911.

"I should not be doing my duty to your workmen if I did not at once tell you, on the completion of your work, how pleased I have been with each and all of them.

"They have been most obliging throughout the whole job, and have endeavoured to do everything in an efficient and thoroughly workmanlike manner, and I must congratulate you upon having such capable employees."

EXHIBITIONS AND MEETINGS.

Perpetual Carnation Show, Leamington.

APRIL 10 and 11.

The energy and enterprise of the Perpetual-flowering Carnation Society found a new outlet in the organisation of a provincial show, which was held in the Winter Hall, Leamington, on Thursday and Friday, April 10 and 11. The object in view was to broaden the sphere of the society's operations, and bring to the immediate notice of Midlanders the claims of the society, and the value and charm of perpetual-flowering carnations. This is a departure which deserves commendation, and the choice of Leamington as the place of the first of these migratory shows was a happy one. It is about as central a spot as could be chosen, and the Winter Hall is a fine, spacious, and well-lit building, admirably adapted to the purpose of a flower show.

As to the display of carnations staged, it may at once be said that in every sense of the word it was a good show. The hall was comfortably filled with exhibits, there being three rows of tables down the body of the hall for exhibits in the vase classes, whilst the ends and both sides were occupied by the trade growers. Decorated tables were accommodated in an adjoining room. Taking a general survey of the hall the effect was pleasing, and it may be remarked that a greater range of colour was evident than would have been possible to obtain with perpetual carnations alone a few years ago. This is unquestionably due, in a large degree, to the many home-raised varieties that have been forthcoming of late, and for which the British growers merit praise.

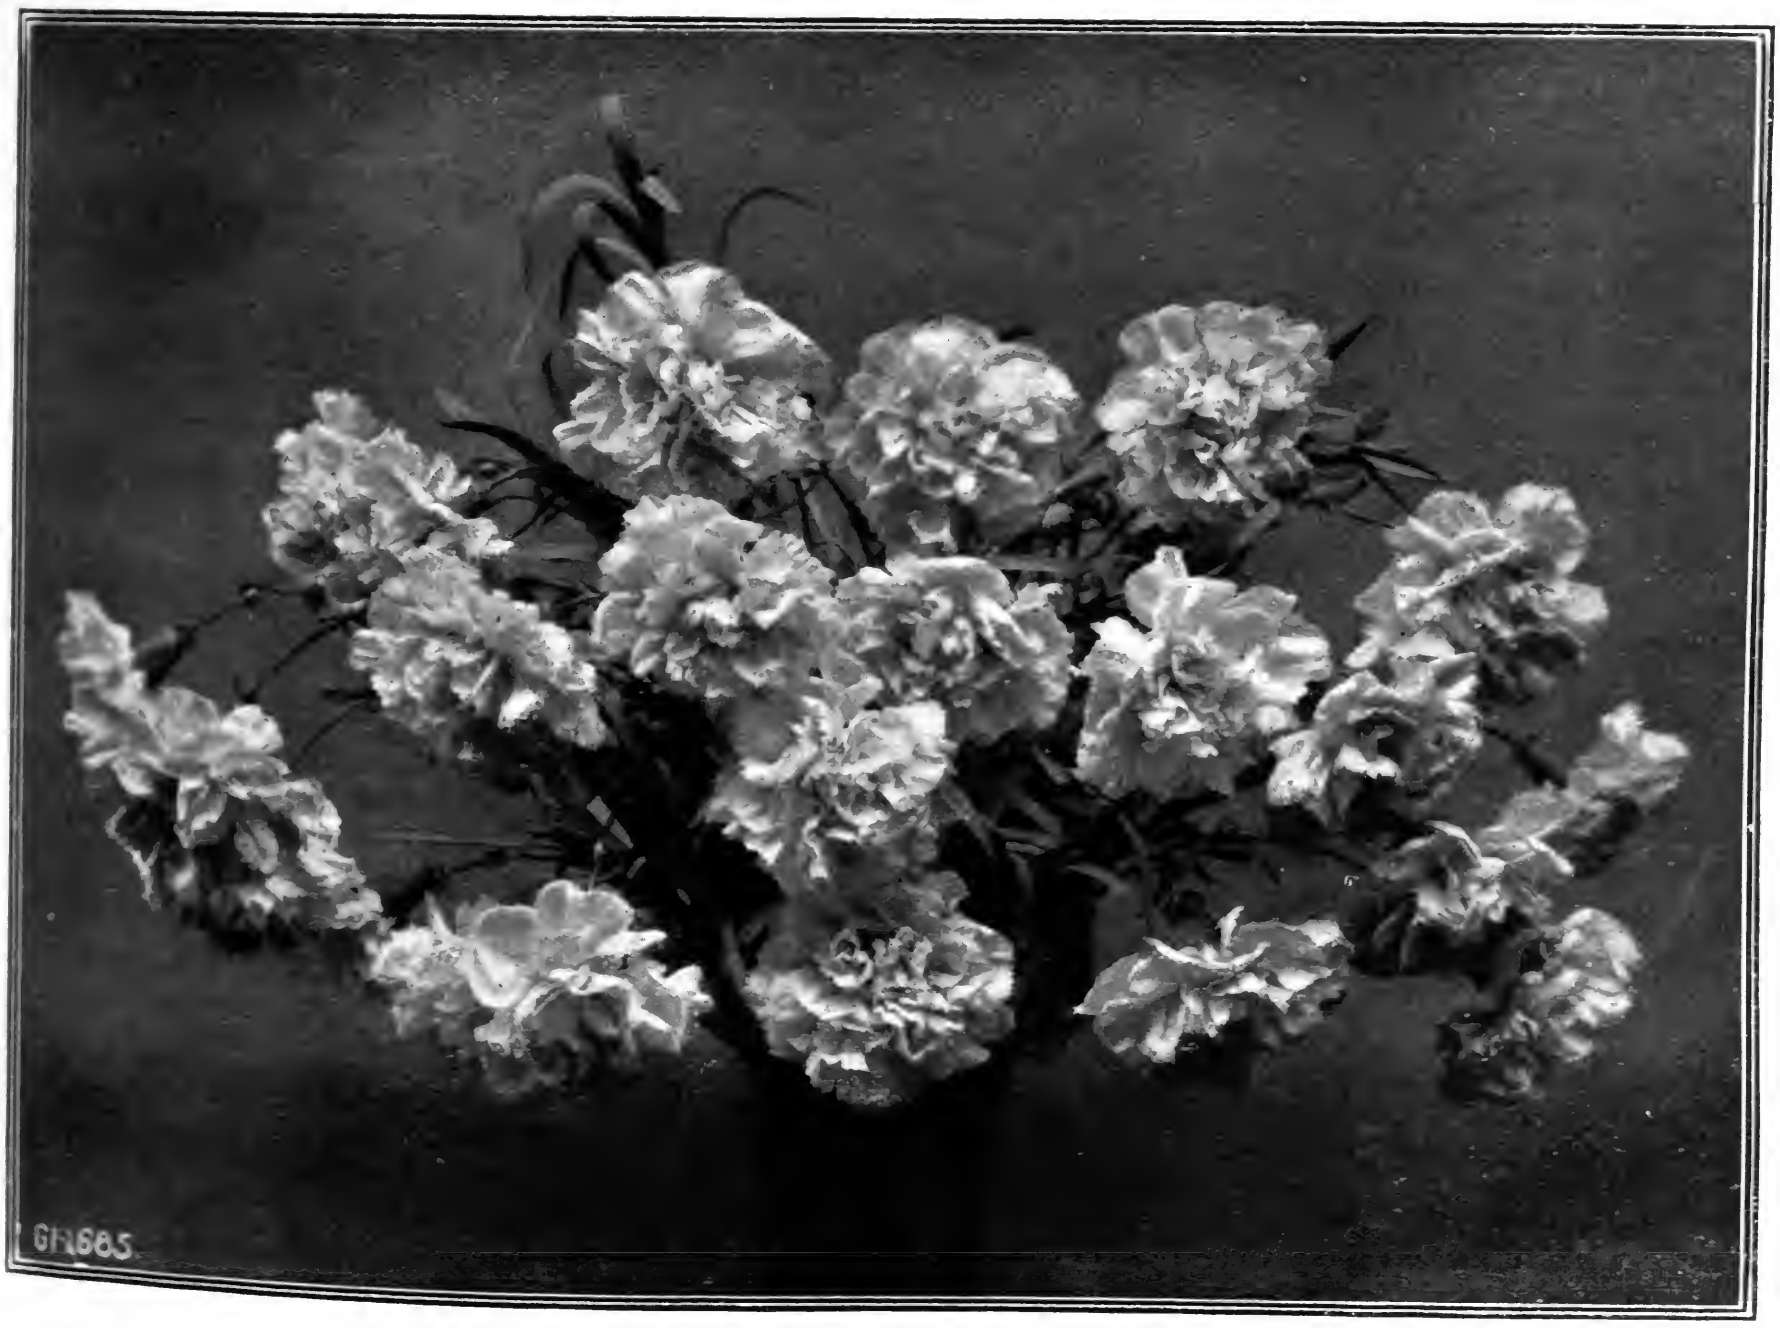
GROUPS OF CARNATION FLOWERS.

The opening class was for a semi-circular group of cut carnations arranged for effect with decorative plants and foliage, for which the American Florists' five-guinea cup and £3 were offered as the premier award. There were two entries, but they were strong, and Mr. C. Engelmann, Saffron Walden, whose exhibit was placed first, may be congratulated on making an exceedingly fine display of beautiful blooms, well arranged, and in choice varieties. The lovely yellow fancy, Sunstar, occupied a prominent central position in the group, and showed its breadth of petal and pleasing colour to advantage. Variegated Corola was one of the most distinct varieties, its rosy-pink and crimson-splashed petals being well placed in a short, stout calyx. Smilax and asparagus were lavishly used to hide the bamboo stands, and give the right setting to a brilliant lot of flowers. Messrs. W. Wells and Son, Lim., Merstham, Surrey, who received second prize, adopted the columnar style of arrangement of their principal stands, filling it with a groundwork of Scarlet Glow, Wodenethe, Triumph, and others. Lady Northcliffe and Gloriosa, two varieties that rather resemble each other, of the coral-pink shade, occupied the most prominent positions, Salmon Enchantress, R. F. Felton, and Dorothy Gordon filling in the background.

VASES OF CARNATIONS.

The Brunton Cup, for three vases of British-raised novelties, was won by Mr. Engelmann with Triumph, My Rose, and Lady Northcliffe. There is no gainsaying that My Rose is a handsome variety, with flowers of excellent form, broad substantial petal, and capital calyx. The stems are, perhaps, a trifle slender, but the colour is fine, and the fragrance delightful. The American Carnation Society offered a challenge cup for three vases of American novelties, the winner in this class being Mr. W. H. Page, Tangley Nurseries, Hampton, who scored over Mr. Englemann. The winning varieties were Gloriosa, White Wonder, and Washington, the last-named being a rich full rose-coloured flower, but rather too small. Benora (some large, well-developed blooms), White Wonder, and Canary Bird were Mr. Engelmann's varieties. The latter is a yellow, rather thin and ragged in appearance, and just faintly tipped with pink on an occasional petal.

A bold display was made with seven vases, distinct varieties, twenty-five blooms of each, Mr. Engelmann leading the way with a very fine exhibit, using varieties we have already mentioned. Colonel F. C. W. Rideout, Clury Nurseries, Langley, Bucks, came second, also showing well-known kinds. Mr. W. H. Page led for five vases, showing Salmon Britannia, a very neat and pleasing flower; Mrs. C. W. Ward, White Wonder, Gloriosa, and Enchantress. Second prize in this class was awarded to Mr. A. E. Usher, gardener to Sir Randolph Baker, Ranston, Blandford, who had Carola amongst his varieties in grand form. Mr. H. J. Dudney, South Road, Erith, coming third. Mr. H. T. Mason, Hampton Hill, Middlesex, won for three vases with White Wonder, Gloriosa, and Lady Meyer, the last-mentioned also securing a special for best vase in the three classes for vases. The same variety took the lead in the single vase classes, this time being staged by Mr. E. Guile, Newport, Essex. Colonel Rideout was placed second with White Enchantress, Mr. Engelmann's Sunstar coming in third. Beacon, shown by Mr. H. T. Mason, received highest honours for the vase of fifty blooms, Mr. Engelmann's Carola being placed second; and Mikado, staged by Colonel Rideout, coming third.



FIRST PRIZE VASE OF CARNATION LADY MEYER.
Exhibited at the Leamington Perpetual Carnation Show by Mr. E. Guile, Newport, Essex.

Messrs. Perkins and Sons, Coventry, exhibited a most beautiful basket of crimson and pale pink carnations, with trials of Asparagus plumosus and croton leaves, and was awarded the first prize; Mr. W. Harper, Leamington, being second; and Mr. W. J. Garner, Hale, Altrincham, third. Messrs. Perkins and Sons repeated their success with bouquets, but took second with three sprays, Mr. Harper excelling in this class.

DINNER-TABLE DECORATIONS.

Some tasteful arrangements of carnations for dinner-table decoration were put up, the successful exhibitor being Mr. A. E. Usher, Blandford. He had an unusually tall centrepiece of very effective design, suitable for a large table, and this he decorated with salmon-pink carnations, croton leaves, and asparagus. Half a dozen small vases were placed around, trails of asparagus running toward them from the base of the centrepiece. Mr. Harper, Leamington, was second with an arrangement that presented a rather stiff and heavy appearance, owing to the flowers having been somewhat too generously used. T. C. Loosemore, Esq., Weymouth, was third with another very pleasing table. In the Warwickshire class for decorated table Mr. H. Cleaver, Newbold Lawn Gardens, Leamington, and Miss L. Hamilton, Studley College, Warwick, were the prize-winners.

AMATEURS' CLASSES.

Some excellent exhibits were staged in the amateurs' section, the classes being so planned that even growers of a very few plants had reasonable opportunity for staging in at least one or two classes. This is an arrangement that will do much to maintain and increase interest in the society and its shows, and is calculated to do much in extending the cultivation of these beautiful flowers. A charming decorative vase of Lady Alington secured a first prize for Mr. E. Burbidge, gardener to Mrs. Fenwick, The Croft, Hillmorton, the blooms being of good quality, and very nicely arranged.

Mr. A. E. Usher had a very good set of seven vases containing seven blooms each, for which he received first prize. R. F. Felton, one of the set, also received special as the best vase in the five leading amateur's classes. Scarlet Glow was also one of Mr. Usher's varieties, its dazzling colour attracting everybody's attention. T. C. Lissmore, Esq., obtained premier honours in the class for three vases, being followed by Miss F. Norman, Moor Place, Much Hadham, Herts. Mr. Usher again won for seven blooms of one variety, showing grand flowers of Carola. Mr. Usher had the best six plants, which were so well grown as to bespeak expert cultivation. Mr. Burbidge, gardener to Miss Fenwick, The Croft, Hillmorton, came second with a nice set in smaller pots, but well grown. Mr. Usher repeated his success in the class for twelve plants, his Sunstar and Triumph being particularly vigorous. There were a number of classes provided by trade growers for varieties of their own raising, Mr. Usher's name appearing with great prominence in these classes as a successful exhibitor.

In the small classes for bone-fide amateurs who do not employ a regular gardener many nice flowers were staged, but the general failing was that they had been cut with stalks much too short, and, consequently, did not display themselves so well as would otherwise have been possible. The prize for the best vase of six blooms in the section went to Rose Enchantress, put up by Stewart Robinson, Esq., The Creole, Kington. Mr. Loosemore, Weymouth, had the best mixed vase of twelve blooms.

Several classes for carnations grown in the county of Warwickshire brought out some very good flowers, and honours were well divided. Miss G. A. Fenwick, The Croft, Hillmorton, had some lovely blooms of R. F. Felton, Lady Alington, and Carola, winning first prize for the three vases. Miss Hamilton, Studley Castle, had the best vase of twelve assorted flowers; and Mr. F. Daniels, The Gardens, Birdingbury Hall, Rugby, scored for nine flowers in variety, and again for six of one variety, showing Carola really well grown.

NON-COMPETITIVE.

Messrs. Allwood Bros., Haywards Heath, Sussex, made a bold and highly attractive display, in which their very bright variety, Mary Allwood, was most conspicuous; there were also several good vases of recently-introduced varieties, including La Rayonnante, Geisha, Wivelsfield Wonder, and Mrs. F. M. Crook.

Another very interesting and attractive stand was that contributed by Messrs. Young and Co., Hatherley, Cheltenham. There were about half a dozen tall epergnes filled with large masses of finely-developed blooms, of such varieties as Mrs. C. W. Ward, Hon. Lady Audley Neeld, Duchess of Devonshire, the deep crimson variety which continue to steadily gain in popularity, and the very pretty fancy, Mrs. Greswold Williams. The table base was furnished with smaller bunches, and neat little vases of half a dozen or so blooms in each.

Mr. A. F. Dutton, Iver, Bucks, used ornamental baskets to hold his flowers. It is a method that enables one to make a novel display, and show the decorative value of the flowers, but we noted that all the stems were rather stiffly wired, giving just a bit too formal an appearance to the stand. His new variety, Mrs. A. F. Dutton, was well shown. It is a very good flower, of rosy-salmon shade, the petals being of good substance, and the stems long and stout.

Messrs. Stuart Low and Co., Bush Hill Park, put up a big mass of Baroness de Brienen, together with good vases of Benora, Fairmount (one of the Mikado type), Colossus, a shapely flower that appeals to us, its colour, size, and substance being good. There were a host of other varieties on this stand, which occupied a large space.

A very long table was well filled with capital flowers by Mr. C. Engelmann, Saffron Walden. The whole of his flowers were splendidly grown, and many very choice varieties were staged. A quite new variety of great promise is Albion, a bright pink flower of perfect outline, on stiff stems that require no support. It has excellent growth, and is a novelty that will become a general favourite. Pocahontas is one of the best-shaped, broadest-petalled crimsons we have seen, and Sunstar, the bright yellow, gives the colour most needed.

MISCELLANEOUS.

Messrs. Hewitt and Co., Solihull, put up a miscellaneous exhibit of azaleas, spiræas, and other flowering plants, over a groundwork of ferns.

Robert Sydenham Limited, Tenby Street, Birmingham, put up a stand of choice daffodils, using the rustic table decorations for the purpose. The idea was excellent, showing these receptacles to be well adapted to the smaller narcissi, which furnish them admirably.

Messrs. R. H. Bath, Lim., Wisbech, also exhibited daffodils, having a number of first-rate varieties on view. Crystal Queen, Peter Barr, and Lady of the Snows were three cream trumpets of merit, and Lucifer, Firebrand, and Scarletta were orange or scarlet-crowned varieties of distinct character.

Messrs. E. A. White, Lim., Beltring, Paddock Wood, Kent, had an exhibit of Abol specialities, showing syringes with adaptable nozzles, fine enough for spraying any insecticide required to be used for carnations. They also had samples of a new shading powder, called the "Abol" shading, obtainable in white, light green, and dark green.

SPECIAL AWARDS.

Large Gold Medal.—To Messrs. Stuart Low and Co., Bush Hill Park, Middlesex; to Mr. C. Engelmann, Saffron Walden; and to Mr. A. F. Dutton, Iver, Bucks.

Silver Medals.—To Messrs. Young and Co., Hatherley, Cheltenham; and to Messrs. Allwood Bros., Haywards Heath.

Award of Merit.—To Sunstar, shown by Mr. C. Engelmann.

Cornwall Daffodil and Spring Flower Society.

This successful society, which enjoys the patronage of Her Majesty Queen Mary and Her Majesty Queen Alexandra, holds an exceedingly interesting show every spring. It is fortunate in possessing as hon. secretary the Hon. John Boscawen, who has held that position ever since the society was first formed, and whose unfailing tact and courtesy render all the arrangements perfect.

This season is such a remarkably early one that at the time of the show, which was held on April 8 in the large Market Hall at Truro, the majority of the daffodils were past their best, with the result that the large class for cut blooms did not fill, greatly to the regret of exhibitors and visitors, who remembered the marvellous stands shown in former years by Messrs. J. C. Williams and P. D. Williams. However, amends were made by the hard-wood flowering shrubs, which have never been so fine as they were this year, a fact proved by the bestowal of a Silver-gilt Banksian medal on the first-prize stand, and Silver Banksian medals on the second and third prize stands.

DAFFODILS.

In the class for the best collection of thirty varieties of daffodil in commerce, the first prize was awarded to Mrs. Soltau-Symons, of Devon, who was awarded a Silver Banksian medal. In the stand were good examples of Scarlet Eye, Cœur de Lion, Incognita, Madame de Graaff, Dorothy, Maggie May, Whitewell, Cavalier, Castile, Ibis, and Beacon. In the class for thirty varieties of daffodil in commerce or not in commerce, the prize was won by Lady Margaret Boscawen, whose Cornish Cream, Garnet, Branston, Will Scarlet, Flamingo, Blood Orange, and Dorothy Kingsmill were very good. In the class for six trumpet varieties, first prize was won by Mrs. Soltau-Symons, who had J. B. M. Camm, Fairy, Madame de Graaff, Mrs. Crosfield, Weardale Perfection, and Emperor. For six incomparabilis varieties first prize was won by Mrs. Soltau-Symons with Lady M. Boscawen, Will Scarlet, Lucifer, Noble, Strongbow, and Whitewell. For six Barri varieties first prize was won by Miss Clarice Vivian with Wheatear, Greeneye, Stonechat, Ptarmigan, Beacon, and Peveril. For six Leedsi varieties first prize was won by Mrs. Soltau-Symons with Citron, Eoster, Maggie May, White Lady, Mrs. Langtry, and Duchess of Westminster. For three poeticus varieties first prize was won by Miss Clarice Vivian with Cassandra, Horace, and Comus. For fifteen distinct varieties first prize was won by Mrs. Soltau-Symons with Lady M. Boscawen, Horace, Eoster, Weardale Perfection, Cassandra, White Lady, Incognita, Madame de Graaff, Castile, Beacon, Seagull, Cresset, Whitewell, Horner, and Cavalier.

The value of the bulbs in eleven classes is limited to ten shillings. Finest trumpet variety—first prize, Miss Mabel Williams, with Monarch; finest incomparabilis bloom—first prize, Mrs. Soltau-Symons, with Lady M. Boscawen; finest Barri bloom—first prize, Mrs. Soltau-Symons, with Cavalier; finest Leedsi bloom — first prize, Mrs. Soltau-Symons, with White Lady; finest bloom of Triandrus and Cyclamineus hybrids—first prize, Mrs. Soltau-Symons, with Dorothy Kingsmill; finest poeticus bloom—first prize, Miss Mabel Williams, with Cassandra.

For fifteen varieties in commerce or not in commerce, price of bulb unlimited—first prize, Mr. J. C. Williams; second prize, Mr. P. D. Williams. These two stands were almost equal, there being very little between them. In the first-prize stand, 312, with primrose perianth and spreading orange crown; 218, white perianth with flat yellow crown edged orange-scarlet; X 3, creamy perianth, pale yellow straight cup; 265, white perianth, deeply formed orange cup; B 5, white perianth, almost scarlet cup; and White Admiral were very fine. In the second prize stand, excellent varieties were White Wax, large white trumpet; Moonbeam, white perianth, small white cup; Snow King, very large poeticus with wide yellow eye, edged

Finest trumpet bloom—first, Mr. F. P. Williams, with Cleopatra; finest incomparabilis bloom—first, Miss Clarice Vivian, with Goldfinch; finest Barri bloom—first, Miss Clarice Vivian, with Wheatear; finest Leedsi bloom—first, Miss L. Williams, with Lavender; finest Triandrus and Cyclamineus hybrid—first, Mrs. Soltau-Symons, with Countess Grey.

MISCELLANEOUS FLOWERS.

Three bunches of anemones—first, Mr. R. H. Henderson-Bull; one bunch of Anemone fulgens—first, Mr. R. Fox; polyanthuses, three varieties in a basket—first, Mr. A. P. Wyatt; primroses (single), three varieties in a basket—first, Lady M. Boscawen; primroses (double)—first, Miss J. E. Lord; collection of hardy spring flowers—first, Mr. P. F. Williams, with Muscari Heavenly Blue, Calochortus platypetala, Narcissus hybrid between Queen Hume and triandrus, Ourisa macrophylla (Award of Merit), Tulipa retroflexa, Primula denticulata, Epimedium sulphureum, Anemone bracteata flore pleno, Erythronium Johnsoni, E. revolutum, Anemone blanda alba, Primula Forresti.

SHRUBS.

The best group of rhododendron blooms came from Mr. J. C. Williams, who showed forty very fine seedlings (Silver-gilt Flora Medal). Mr. J. C. Williams also obtained a Silver Banksian Medal for a collection of the following rhododendrons: R. Yunnanense, R. concinnum, R. oleæfolium, R. intricatum, R. racemosum, R. Augustini. For three large pots of sprays of outdoor rhododendrons, Mr. R. Fox was first with R. arboreum, crimson, white, and pink; one jar—first, Mr. D. B. Shilson, with Cornubia, crimson-scarlet; finest bloom of camellia—first prize and Award of Merit for Lady Buller.

For a group of hard-wood flowering shrubs Rev. A. T. Boscawen came first (Silver-gilt Banksian Medal). The stand contained Ribes speciosum, Spiræa argnta, Erica melanthera, Kennedya latifolia, Boronia heterophylla, Acacia verticillata, Prostanthera violacea (a beautiful purple-flowered shrub found by Capt. Dorrien-Smith in New Zealand), Veronica macrocarpa, Cytisus albus, Pentapteriginia rugosum (Award of Merit), Ceanothus azureus, Pernettya ciliaris (Award of Merit), Viburnum Carlesi, Andromeda acuminata, Fuchsia cordifolia, Correa magnifica, Pyrus japonica, P. j. alba, Pittosporum eugenoides, and Erica mediterranea. The deputation from the Royal Horticultural Society were delighted with the excellence of the display in this class, and expressed themselves amazed at the variety of the exhibits.

Mr. T. A. Dorrien-Smith, of Tresco Abbey, Isles of Scilly, exhibited a marvellous selection of rare plants in flower, these including Arctotis arborescens, A. aureola, an enormous flower-spike of Brachyglottis reinoldi, Grevillea sulphurea, G. Thelmanniana, G. alpina, G. rosmarinifolia, Acacia longifolia, A. Hartheriana, A. verticillata, A. cyanophylla, Correa virens, C. ventricosa, C. cardinalis, C. Harrisi, C. magnifica, C. alba, C. bicolor, C. picta, Sophora grandiflora, Fuchsia exoniensis, Echium callithyrsum, and two hybrid Echiums, Beschorneria yuccaoides, Sedum arboreum, Kennedya nigricans, Fuchsia serratifolia, Psoralia affinis, Agonis marginata, Illicium anisatum, Leucopogon lanceolatus, Fuchsia cordifolia, Coleonema album, Pittosporum Tobira, P. T. variegata, and a wonderful collection of other pittosporums, including P. Ralphi, P. Colensoi, P. Mayi, P. eugerioides, P. undulatum, P. umbellatum, P. bicolor, P. cornifolium, P. crassifolium, and P. crassifolium. A gold medal was awarded to this collection. The Rev. A. T. Boscawen received a First-class Certificate for Grevillea Hookeriana, a plant bearing numbers of bright red flowers, in shape somewhat resembling a bottle-brush.

MISCELLANEOUS EXHIBITS.

The attractions of the show were much enhanced by the nurserymen's exhibits.

Messrs. Barr and Sons, Covent Garden, had an exceptionally good display of daffodils, for which they received a silver-gilt Flora medal. Among the flowers were Chamois, Olympia, Maid of Athens, Lohengrin, Chancellor, Peter Barr, Icepeak, Sunrise, Minerva, Buccaneer, Pyramus, Calpurnia, Penguin, Seraphin, Marie Louise, Buttercup, and Torchlight, all uncommon varieties. Mr. C. Bourne, Bletchley, also showed daffodils, for which he was awarded a Silver-gilt Flora Medal. In the stand were Incognita, Bernardino, Golden King, Radiant, White Countess, Lemon Queen, White Slave, Goldfinch, and Little Joan. Mr. J. C. Martin also showed daffodils, and was awarded a Silver Banksian Medal. Among his varieties were Bowerbird, Gullrock, Eaglet, Bronze Queen, Carnation, Kingfisher, Brunette, and Silver Penny. Messrs. Barr were given an Award of Merit for Daffodil Venus, and Mr. J. C. Martin for daffodil Silver Penny.

Messrs. R. Veitch and Son, Exeter, had a most interesting stand, in which were Raphiolepis indica rubra, Gerbera hybrids, Psoralea arborea, Agapetes buxifolia, Camellia reticulata, Daphne cneorum, Lonicera nitida, Grevillea longifolia, Exochorda Alberti macrantha, Magnolia Kobus, Acacia acinacea, Genista elegans, Grevillea alpestris, Lewisia Howelli, Osmanthus Delavayi (Award of Merit), Senecio rotundifolia, and Lotus peliorhyncus. Mr. G. Reuthe, Keston, staged Ribes australis, Rhododendron Elsæ (Award of Merit), Trillium erectum, Fritillaria armena rubra, Arctostaphylos Stanfordiana, Olearia angustifolia, Anchusa myosotidifolia, Sarracenia purpurea, Soldanella montana, Myosotidium nobile, Omphalodes nitida, Veronica pimelioides, Stachys corsica, Veronica Armstrongi, and Corokia virgata. This stand was awarded a Silver Flora Medal.

The Devon Rosery, Torquay, showed a fine collection of pot roses in full bloom, amongst which were Earl of Gosford, Archduchess Marie, Immaculata, Aunchen Muller, Climbing Kaiserin Augusta Victoria, Countess of Gosford, Liberty, and Ma Capucine. They also exhibited Pyrus malus angustifolius, P. m. Scheideckeri, new weigelas, Acacia verticillata, A. pendula, Boronia elatior, B. heterophylla, and Erica persoluta alba. They also showed a large number of fine apples, of which Lane's Prince Albert, Winter Peach, Belle de Pontoise, Bowhill Pippin, and Bramley's Seedling were especially good. They were awarded a silver medal.

Messrs. Treseder, Truro, staged six enormous plants of Dicksonia antarctica, with wide-spreading fronds, Spiræa Queen Alexandra, Acacia Drummondi, A. armata, A. longifolia, Eriostemon neriifolium, Cyrtomium Rochfordi, Senecio Greyi, Erica australis, Acacia cordata, A. linifolia, and Indigofera australis.

East Anglian Horticultural Club.

At the April meeting two papers were read in a competition upon "The Growing of Decorative Chrysanthemums for the Best Results." The first prize was awarded to the one sent in by Mr. C. H. Fox, Catton House Gardens, who dealt practically with his subject, both from the market man's and private grower's point of view. Mr. D. Howlett kept entirely to the private grower side, and aimed at perfection in pot culture. His points were just those one would follow to have a healthy-looking plant with foliage down to the rim of the pot. Pests and insects were well treated upon. The subject brought out an animated discussion. There was a good exhibition of flowers, pot plants, and vegetables, giving the room a charming appearance. Messrs. Daniels Bros., Lim., Norwich, sent forced shrubs. Hobbies, Lim., sent roses. Mr. Frank Neave made a fine feature of pelargoniums. Mr. W. Shoesmith, gardener to F. W. Harmer, Esq., achieved a great success with strawberries and orchids, while the President (Mr. F. Williams) had beautiful examples of azaleas and mignonette. During the meeting the question of the summer outing was discussed, and it was decided this year to go to the Cambridge Botanic Gardens on Thursday, July 24.

Royal Horticultural Society.

The two-day exhibition held on April 15 and 16 at the Royal Horticultural Hall was a very fine one, and everyone seemed agreed that it was one of the very best yet held. The daffodil fanciers had a great time, and in the competitive classes exhibits were numerous, with but few exceptions, while the new flowers were delightful. Orchids were not so plentiful as usual, but hardy flowers, alpines, roses, and carnations were shown largely and well.

There was some little grumbling because the remains of an exhibition held the previous week were not cleared early enough on Monday, April 14, by the time many exhibitors reached the hall. The orchid people also had a grumble because at first it seemed that plants submitted for award would have to remain the two days. The Rev. W. Wilks made matters easy for the orchidists, and all through a rather trying time Mr. Smith—who acted as show superintendent in Mr. S. T. Wright's absence because of indisposition—was suavity itself.

The veteran, Mr. John Heal, V.M.H., received many congratulations upon the completion of fifty years' service in the employ of Messrs. J. Veitch and Sons, while Mr. P. R. Barr was a happy and proud man after the Narcissus Committee had awarded him the Barr Memorial Cup for the ensuing year.

The attendance on the first day was very large, inconveniently so, but there were very few people present between six and eight o'clock in the evening.

FLORAL COMMITTEE.

Prof. J. Bayley Balfour, Royal Botanic Gardens, Edinburgh, sent a beautiful collection of primula species to illustrate his lecture at the Primula Conference on Wednesday, April 16. Primula Reidi, with its heads of drooping white, bell-shaped flowers, and with farina on stems and calyces, was a most charming little plant, and was greatly admired; with this were P. Forresti, P. malacoides, P. Juliæ, with its blue flowers and neat campanula-like leaves; P. nessensis, P. pinnatifida, P. Geraldiana, and several other kinds.

Mr. Jas. Douglas, Edenside, Great Bookham, staged some wonderful auriculas, which attracted much attention from the visitors. Some of the best forms were John Ridd, May Day, Favourite, Lady Veitch, a grand claret variety; Harrison Weir, and Mrs. Jas. Douglas; also a fine plant of Myosotidium nobile, carrying some fine heads of flower. From Messrs. Phillips and Taylor, Bracknell, came a nice display of auriculas and hardy primulas.

Some beautiful alpine auriculas were set up by Messrs. Jas. Veitch and Sons, and the yellow Buttercup was very attractive; the same firm exhibited nemesias in pots—Blue Gem was a very lovely variety of soft blue colour—Primula obconica, and some handsome hippeastrums, the rounded, deep rosy-red variety Eurasian gaining an Award of Merit. The Chelsea firm exhibited standard plants of varieties of Azalea indica, and, by way of contrast, staged Androsace tibeticum, about two inches high, with clusters of little pinky-blush flowers (A.M.). Mr. J. Crook, Camberley, massed a very fine and bright lot of polyanthuses, and Messrs. Bakers, Wolverhampton, presented various saxifrages, the pretty Ranunculus montana, with golden flowers, Incarvillea grandiflora, and the dainty dwarf iris named Bluebeard.

Rhododendrons from Messrs. R. Gill and Sons, Falmouth, were a fine display, and in the exhibit the grand blooms of the white R. Nuttali and the yellow R. Dalhousie were splendid.

Messrs. Sutton and Sons, Reading, had a most pleasing exhibit of cinerarias arranged in masses of colour; these included varied shades of pink, scarlet, blue, and so on, the plants were dwarf, and carried fine heads of inflorescence.

The bottle-brush tree (Metrosideros floribunda) and the tall spiked rosy-flowered Erica King Edward VII. were well shown by

Messrs. Stuart Low and Co., Enfield. Messrs. H. B. May and Sons, Upper Edmonton, had a large miscellaneous exhibit.

Zonal pelargoniums were staged by Messrs. H. J. Jones' Nurseries, Lim., Lewisham, in capital form. Messrs. H. Cannell and Sons, Swanley, sent a glorious bank of zonal pelargoniums, which were remarkable for their size and brilliant colours.

Messrs. W. Cutbush and Son, Highgate, presented a small display of carnations arranged in bamboo stands. Mr. H. Burnett, Guernsey, had an exhibit of glorious perpetual carnations, and he had the yellow Mandarin in fine form among the more popular varieties. Messrs. Allwood Brothers, Haywards Heath, also did well with carnations.

Messrs. G. Jackman and Son, Woking, also presented hardy plants, tastefully arranged. the saxifragas. Iris Susiana was flowering in splendid condition, as were also the dwarf irises.

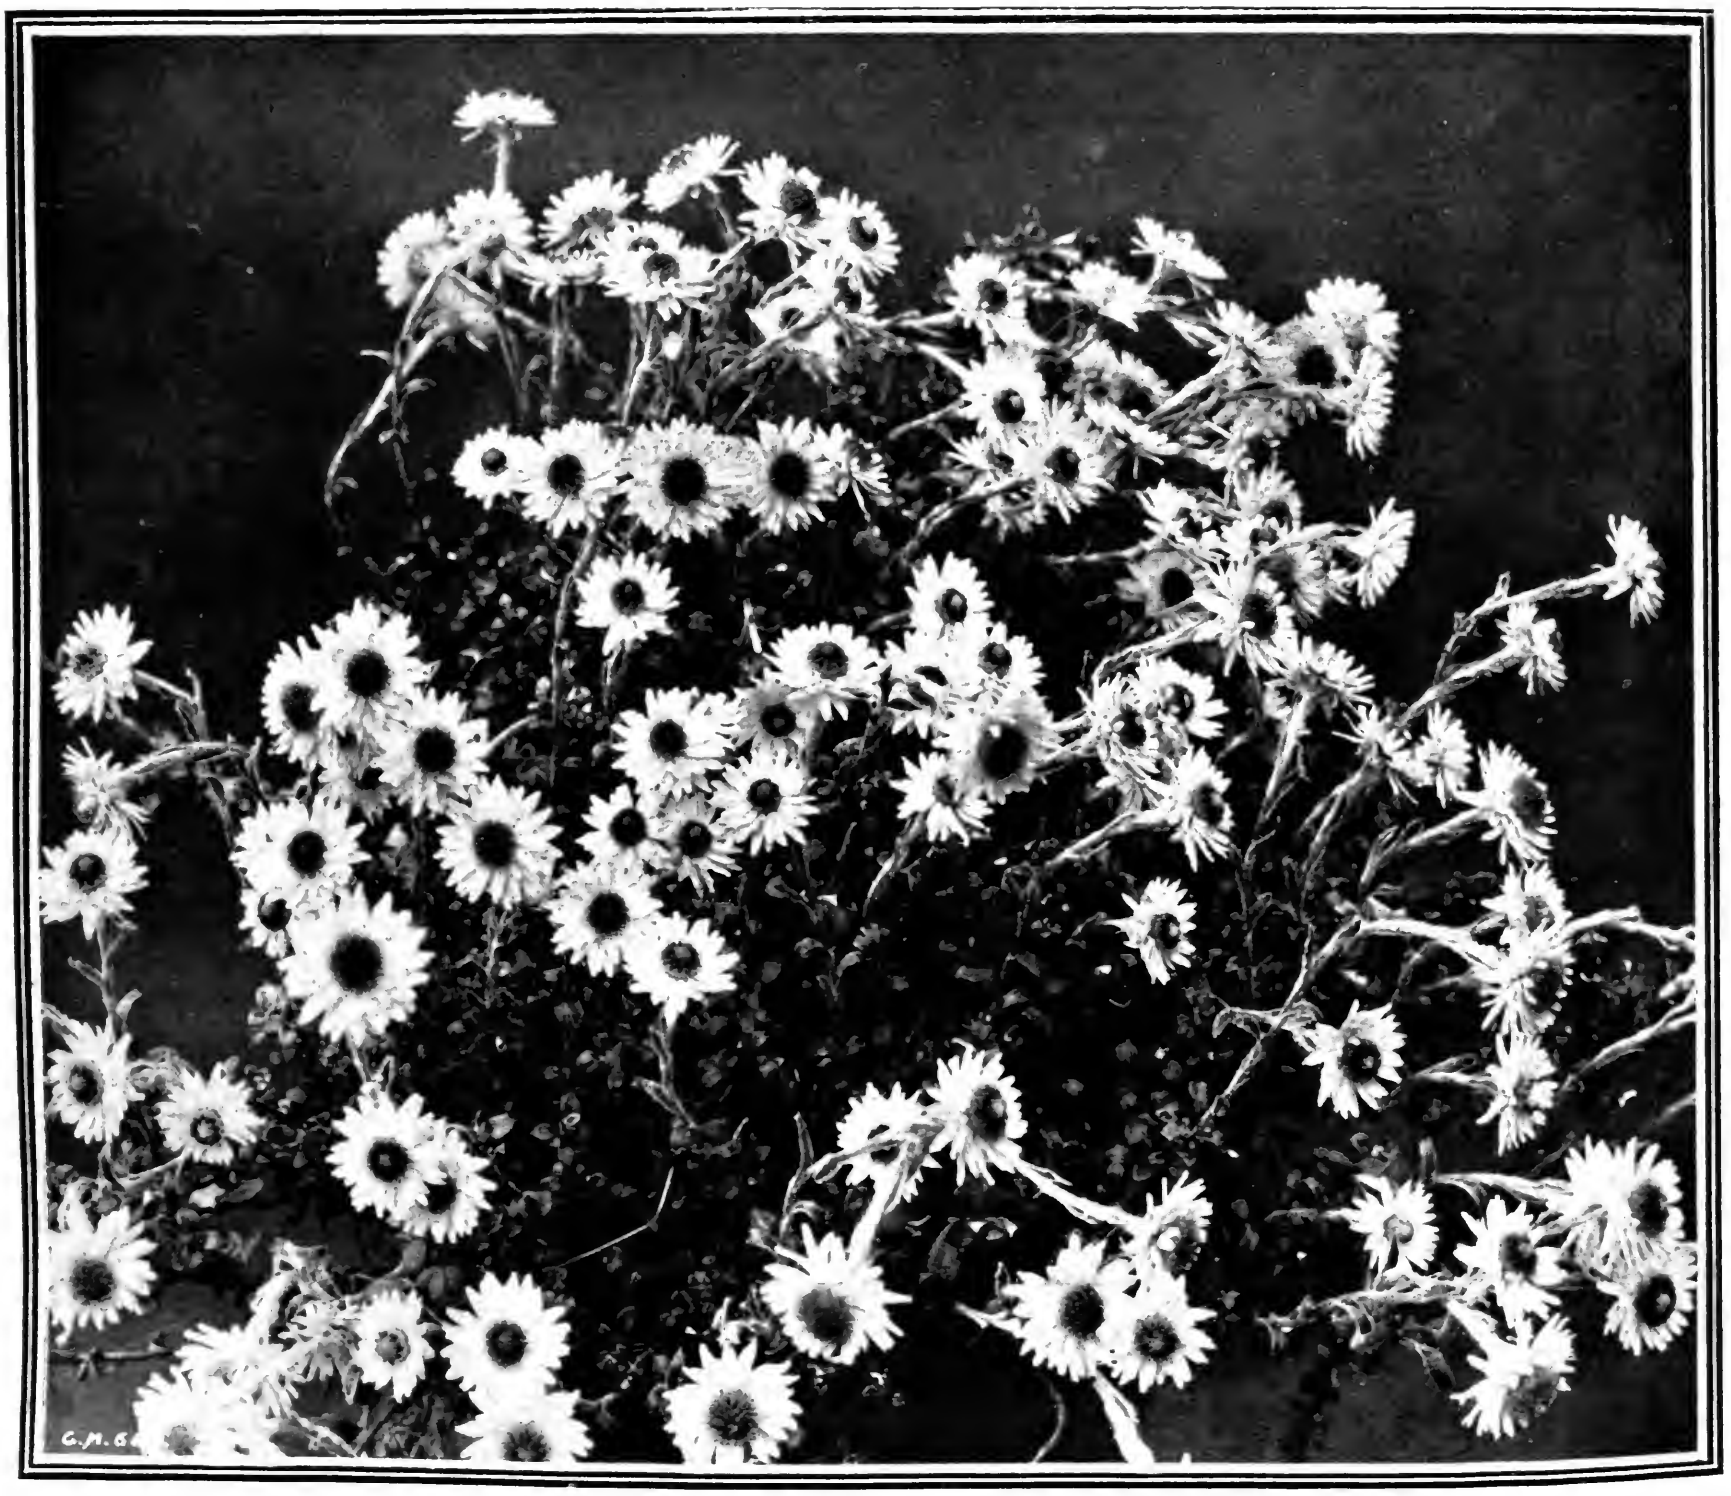
Mr. James Box, Lindfield, Haywards Heath, occupied a corner of the hall with rock and alpine plants tastefully arranged with sandstone. The background was formed with acers, cedrus, veronicas, and similar plants, while a fine collection of alpines were grouped in the front.

Mr. R. d'E. Day, Sutton Scotney, Hants, made a bright exhibit of Spanish irises, which he appears to grow to perfection. The best forms were Cajanus, Blanche Fleur, King of the Blues, and Raphael. Mr. E. C. Bowell, Cemetery Road, Cheltenham, exhibited a collection of rock plants in pots arranged in moss; some of the best subjects were Arabis Billardieri rosea, Saxifraga Strachyi alba, and Anthemis Hauschnechli.

noted a large variety of aubrietias, primulas in variety, saxifragas, Viola gracilis, Arenaria grandiflora, and some good examples of double primroses, while acers, pinuses, and azaleas were utilised to make a background. Messrs. T. S. Ware, Lim., Feltham, were represented by a pretty and well-arranged rockery, on which the alpines looked particularly at home. Some of the chief subjects were Aubrietia Dr. Mules, Conandron ramondioides, Erysimum helveticum, with Primula rosea, marginata, and viscosa in fine form.

From Messrs. Blackmore and Langdon, Bath, came a fine strain of polyanthuses arranged in blocks of colour, the white, crimson, and yellow forms being especially fine.

Messrs. B. R. Cant and Sons, Colchester, arranged a nice display of roses in the Annexe, and roses were charmingly shown by Mr. George Prince, Longworth.



HELICHRYSUM BELLIDOIDES.

Flowers white. A.M., R.H.S., April 15. Mr. A. Hemsley, Crawley.

Primula Sieboldi was bright and clean, Morisia hypogæa was a mass of golden flowers, while Iris Excelsa, I. cyanea, I. Eburnia, and I. florida were quite attractive, arranged in masses. Messrs. Whitelegg and Page, Chislehurst, showed alpine phloxes, aubrietias, red saxifrages, Viola papilio, and the blue Gentiana acaulis in round baskets. Mr. C. Elliott, staged a small rockery, on which were to be seen Gentiana acaulis, Morisia hypogæa, saxifragas, and Androsace Chumbyi. From Mr. G. W. Miller, Clarkson Nursery, Wisbech, came a spring-like show of polyanthuses, pansies, daisies in variety, double primroses, and arabis, all remarkably well developed.

The Wargrave Hardy Plant Company, The Arcade, Liverpool Street, exhibited a fine table of alpine plants in the Annexe. The aubrietias were a fine feature, as were also

From Messrs. R. Wallace and Co., Colchester, came an attractive group of alpines arranged naturally. Aubrietias in variety were attractive, as were also patches of Saxifragas Clibrani, and S. L. G. Godsell. Tulipa stellata was also to be seen; while Primula Juliæ and P. denticulata were prominent amongst other plants. Mr. Maurice Prichard had a lovely mass of the rosy free-flowering and deliciously fragrant Daphne cneorum in the centre of a rock garden exhibit, where aubrietias, saxifragas, and primulas were abundant and beautiful. Messrs. G. and A. Clark, Dover, massed vigorous and brilliant polyanthuses, St. Brigid anemones, and the fine double geum, Mrs. J. Bradshaw, in bold fashion.

Messrs. J. Cheal and Sons, Lim., Crawley, Sussex, occupied the end of a double table with a display of rockery, on which were

The new White Tausendschon rose, exquisitely beautiful, with fine clusters of large semi-double, white flowers, was shown grandly by Messrs. Wm. Paul and Son, Waltham Cross, Herts, and was the feature of their group of climbing roses, though Rowena was also a fine variety, finely shown.

Messrs. J. Macdonald and Son, Harpenden, again showed grass raised from seeds sown on a canvas preparation, ready for laying down to form a lawn.

ORCHID COMMITTEE.

Trichopilia Backhousiana, with its drooping spikes of white and cream flowers, was very finely represented in the group staged by Messrs. Hassall and Co., Southgate; Cymbidium eburneo-Lowianum, and Miltonia Bleuana grandiflora were also fine in this group. Mr. A. Harrison, Oneglia, Italy.

sent a few dendrobiums; and Mr. E. H. Jenkins, Orchid Dene, Twyford, put up some grand spikes of fine odontoglossums, Cypripedium Hassalli with wine-coloured dorsal sepal; Odontoglossum Aurora, one of the Rosa hybrids, was conspicuous in this group.

Odontioda Devonsiana was shown by Mr. Ashforth, gardener to F. Menteith Ogilvie, Esq., The Shrubbery, Oxford; it bore a spike nearly 4ft. long, with numerous branches of mulberry-purple flowers. Mr. G. F. Waters, Balham, and Messrs. J. and A. McBean, Cooksbridge, showed a few orchids. Messrs. Sander and Sons, St. Albans, presented good forms of the fragrant Cattleya Schröderæ, the bright Renanthera Imschootiana, Brassocattleya Langleyense, B.-c. Empress of India, and the new Maxillaria Fletcheriana, with creamy sepals lined with rose; the petals have deeper lines, and the lip is dull tawny yellow. This gained an A.M.

A nice group of orchids from Mr. Sidney Tracy, Tracy's Nursery, Twickenham, contained goodly spikes of odontoglossums, cattleya Schröderæ, Brasso-cattleyas, masdevallias, chrysisbractescens, and other good things. A glorious flower was Lælio-cattleya Ingramii Holford's var. (F.C.C.), with lovely yellow sepals and petals, and an intense rich purple lip with paler rim; this was shown by Mr. H. Alexander, orchid grower to Sir George Holford, Westonbirt, Tetbury. From the same collection came Odontoglossum Pescatorei Lady Holford (F.C.C.), with unusually large flowers, the sepals tinted with rose, and the white petals each with a single purple spot.

Cattleya Robert de Waverin, with a brilliant light purple lip, was finely shown by Mr. Davis, gardener to J. Gurney Fowler, Esq., Glebelands, South Woodford. Oncidium concolor, Phalænopsis Aphrodite, the lovely Brasso-cattleya Queen Alexandra, and a fine form of Lælio-cattleya Dominiana were shown in capital condition by Messrs. Charlesworth and Co., Haywards Heath. Mr. H. S. Goodson (gardener, Mr. Day), Putney, contributed odontoglossums, odontiodas, masdevallias, and the chaste Cattleya intermedia alba.

DAFFODIL COMMITTEE.

A very fine group of daffodils from Messrs. Barr and Sons, Covent Garden, was a centre of attraction for specialists. Some of the finest things were Ceadmon, a fine poet (A.M.) with a crimson rim to the orange-yellow cup. St. Olaf, a lovely broad-crowned Leedsi form (A.M.), with white, broad perianth and pale cream-tinted, crimpled crown, was generally liked. Other fine varieties were Torchlight, White Knight, Altkönig, a golden jonquilla hybrid; Miss Willmott, Southern Gem, the handsome Cœur de Lion, and Tara Ranee, with broad golden-orange crown. The Wargrave Plant Farm, The Arcade, Liverpool Street, had a small stand of daffodils, and Messrs. Sutton and Sons, Reading, put up blocks of such varieties as Cardinal, Argent, Red Crest, Lady Mary Boscawen, Red Flag, and Southern Gem, with smaller sets of Evangeline, Incognita, and Homespun, all excellent varieties. Messrs. Backhouse, Sutton Court, Hereford, brought up a few seedling daffodils, and Gauntlet, with vivid orange crown, was the most striking variety.

Unusually fine were the Darwin tulips grown in bowls of fibre, without drainage, by Messrs. R. H. Bath, Lim., Wisbech. This was a first-rate exhibit, and one that cannot fail to gain many adherents for "fibre culture." Mr. Farncombe Sanders was over a yard high, and carried grand flowers. Mr. A. Hemsley, Crawley, showed a small collection of daffodils, but crowded his blooms somewhat. He staged Helichrysum bellidioides (A.M.), a low-growing, creeping, white-flowered, everlasting flower of perennial habit, and perfectly hardy. King Alfred was a daffodil finely shown in the group of flowers displayed by Messrs. Jas. Veitch and Sons.

Very bold and effective was the great sheet bank of daffodils arranged by Messrs. Jas. Carter and Co., Raynes Park. It was a high bank, with a few contrasting conifers, and the varieties massed were White Lady, Homer, Gloria Mundi, Mdme. de Graaff, Incognita, Duchess of Westminster, Dazzler, Firebrand, Beauty, Albatross, and Barri conspicuus. Some capital daffodils were staged by Robert Sydenham Limited, Tenby Street, Birmingham, and some of the best on view were Horace and Brighteye, poeticus varieties; Beacon, Red Chief, Will Scarlet, Rosella, Cresset, and Watchfire, all with brilliant orange crowns, and such useful old varieties as Mdme. de Graaff and Queen of Spain.

Mr. Christopher Bourne, Bletchley, staged some beautiful vases of tulips; Mrs. Moon, City of Haarlem, Moonlight, the splendid mahogany-coloured King Harold, Inglescombe Pink, and Bouton d'Or, were lovely. Mr. Bourne had also a number of fine daffodils, a few of his best being Golden Idol, trumpet; Great Warley, with wide and deep golden crown; Queen of Hearts, a fine bit of colour; Little Joan, a dainty little white Leedsi; and Red Lady, with a neat deep orange cup. From Lissadel, Sligo, came some capital daffodils, many of them being unnamed seedlings. Whitewell, Incognita, Seagull, the creamy-white Atalanta, White Queen, and the fine white trumpet variety Mrs. R. Sydenham were a few of the outstanding named sorts. Triandrus hybrids were very pretty. Messrs. Walter T. Ware, Lim., Bath, had a few fine daffodils on view, and their pièce de résistance was Europa (A.M.), a giant trumpet variety, a bicolor with broad light yellow trumpet and widespreading white perianth segments. Campernelle The Giant was very striking, and it should make a fine garden daffodil.

Very choice were the new daffodils shown so finely by Mr. A. M. Wilson, Shovell, Bridgewater, Somerset. A large number of the newest sorts were under number, and these included some lovely poeticus varieties, but a few of the finest named kinds were Brambling, Ceres, with flat golden crown; the exquisite Buttercup; Centurion, with a frilled pale yellow trumpet; Madrigal, with orange crown; Abigail, a fine pale cream trumpet variety. Messrs. E. H. Krelage and Son, Haarlem, showed the lovely white trumpet variety, Mrs. Ernst Krelage, and gained an F.C.C. for it; it is a grand, symmetrical and substantial daffodil.

Among the daffodils displayed by Messrs. J. R. Pearson and Sons, Lowdham, we made special note of the brilliant little Firebrand, the creamy magnate Homespun in fine condition, Macebearer, with orange-yellow cup; Homer, a famous poet; and Florence Pearson, one of the best of the creamy trumpet varieties. Messrs. Cartwright and Goodwin, Kidderminster, displayed their flowers, as usual, with isolepis, and had a pretty exhibit. Crœsus, Southern Gem, Matthew Arnold—a dark-eyed poet, Chancellor, and the white Lord Kitchener were a few leading varieties. Last, but not least, the Rev. G. H. Engleheart, V.M.H., Dinton, Salisbury, had a wonderful exhibit of new daffodils, all under number; his poeticus varieties were exquisite—especially one labelled 700A; and the broad-crowned varieties were not less beautiful.

FRUIT AND VEGETABLE COMMITTEE.

Messrs. Sutton and Sons, Reading, made a really brave show of vegetables for the season. The background was formed with mounds of Broccoli Latest of All, Cabbage Sutton's April, and some fine examples of the Sutton Rhubarb, while Lettuce Golden Ball and Sutton's White Heart were to be seen. Some splendid pods of Pea Duchess of York attracted the visitors. French Beans Princess of Wales and Tender and True were fine in colour, while asparagus, cucumbers, tomatoes, mushrooms, radishes, seakale, carrots, and turnips were also seen in fine condition; in fact, it was a remarkable collection for the early period.

Mr. A. Metcalfe, gardener to Lady Wernher, Luton Hoo, Luton, gained a cultural commendation and Silver Banksian Medal for a grand lot of forced fruits of Royal Sovereign strawberry.

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

Be sure and purchase "Twentieth Century Gardening," by John Weathers. 300 pages. **1/-** nett. To be obtained of all Booksellers.

If unobtainable, sent post free on receipt of P.O. 1/4

Full particulars from

CHEMICAL UNION, Ltd, IPSWICH.

London Daffodil Show.

VINCENT SQUARE, APRIL 15 and 16.

It has been said repeatedly that the Narcissus Committee of the Royal Horticultural Society have been lacking in their duties towards the claims of the daffodil, and that they have not pushed these hard enough, but the show held on Tuesday last should teach the critics that the committee are quite alive to the needs of the case.

There were no less than fifty-two classes, most of them filled, and it can safely be said that a finer display of daffodils has never been seen in the hall before. The Council of the R.H.S. generously give a large number of cups and medals as prizes, and the Schedule Sub-committee of the Narcissus Committee makes itself responsible for the cash awards. We congratulate the Society and the Committee upon the success of the show.

The premier open class for a collection of daffodils, in forty-eight varieties of three stems each, brought out a strong competition, there being five entries, the first prize, a gold medal or silver cup, being awarded Mr. E. M. Crosfield, Cossington House, Bridgewater, who staged a really fine display. The flowers were beautifully clean and bright, and were a thorough representative collection. The most conspicuous vases were Radiant, Mowglie, Samson, Dictator, Hela, Lolah, Mrs. E. Crosfield, Tiara, Frostbound, Charles Surface, and Ring Dove, also some fine seedlings under numbers. The second prize was awarded Mr. F. H. Chapman, Rye, Sussex, who staged clean, bright flowers, but they were a considerable distance from the winner. A few of the best specimens were Mrs. Veitch, Heroine, Tritoma, Ibis, Alys, Will Scarlett, Maggie May, Minstrel, Sea Horse, and quite a quantity of seedlings under number. Mr. Christopher Bourne, Simpson, Bletchley, was third, having fine examples of Queen of Hearts, Red Lady, Mrs. Veitch, Florence Pearson, and Zenith.

For twelve bunches of large trumpet varieties, Messrs. E. H. Krelage and Son, Haarlem, was awarded first prize for a very handsome display. The flowers might have been gathered an hour previously, so fresh were they in appearance. The varieties employed were Hope of Holland, South Pole, Glory of Haarlem, Frans Hals, Mrs. E. H. Krelage (a splendid variety), Thackeray, Duke of Bedford, and fine seedlings, all of great promise. Messrs. Cartwright and Goodwin, Kidderminster, were a capital second, the best forms being Caradoc, Mrs. H. J. Veitch, Onslaught, King Alfred, King Solomon, Diogenes, and Master of Balliol, while Mr. W. A. Watts, St. Asaph, secured third place.

The class for twelve Incomparabilis varieties only secured two entries, Mr. W. A. Watts winning first prize with a charming exhibit. The best varieties were Great Warley, Homespun, Orangeman, Perseus, and Whitewell; Messrs. Cartwright and Goodwin won second prize with a good level exhibit, their best examples being Cigar, Furze Bloom, Mrs. W. Miles, and Red Sunbeam. The Barri section was better supported. For twelve varieties, three stems each, there were four entrants. Mr. C. Bourne was first, the most noteworthy varieties being Red Chief, Incognita, Queen of Hearts, Red Eve, and Zenith. Mr. F. H. Chapman was second with well-arranged vases of Ethelbert, Senator, Rotherside, and Equinox; while Mr. W. A. Watts was third.

The class for nine Leedsi varieties was represented by four exhibitors, Mr. Chris-Bourne winning first prize with fine examples of White Lady, Lord Kitchener, Evangeline, Little Joan, Dewdrop, and Bianca. Messrs. Cartwright and Goodwin were second, having good vases of Mrs. W. O. Wolsley, Aquarius, Leading Lady, and Eddington; while Mr. W. A. Watts was third. The Poeticus division was not strongly represented, only three competitors staging nine distinct varieties. Mr. C. Bourne led off with fine sorts, some, however, being on the side of youth the first day. The most prominent varieties were Acme, Geo. Herbert, Tennyson, Black Prince, Stephen Phillips, and Virgil; while Mr. W. A. Watts secured the third prize.

Two competitors shared the honours in the class for nine Polyanthus (Tazetta) varieties. Messrs. Cartwright and Goodwin secured the first prize with good typical examples of Irene, Alsace, Jaune à Merveille, Klondyke, and Orient. Mr. W. A. Watts was second with Irene, Maestro, and Jaune à Merveille in fine form. Strange to relate, there were only two exhibits of double daffodils in six varieties. Mr. W. A. Watts led off with clean, fresh examples of Codlins and Cream, Golden Rose, and Primrose Phœnix; the other vases were rather weak. Messrs. Cartwright and Goodwin were second with Inglescombe Phœnix, Whirligig, and Primrose Phœnix in capital condition.

The collections of daffodils in twenty-four varieties secured a strong entry, no less than five collections being staged. The first prize was well won by Mr. N. G. Lower, Presteign, who staged his flowers in perfect condition. The most striking were Sunrise, Olympia, Weardale Perfection, Bernardino, Will Scarlet, Glory of Leiden, Horace, and Beacon. Mr. S. F. Staffworth, Frieston Priory, Boston, was second, having good bunches of Glory of Leiden, Weardale Perfection, King Alfred, Cigar, Orangeman, Diogenes, and Mohican. The Rev. T. Buncombe, Black Torrington, was a good third, his varieties of Albatross, Harold Fynn, Weardale Perfection, Horace, and Treasure Trove being especially good.

For six long trumpet varieties, the Rev. T. Buncombe won handsomely with clean, bright examples of Emperor, Weardale Perfection, Treasure Trove, Sybil Foster (very fine), Madame de Graaff, and The Colonel; Mr. W. B. Cranfield, East Lodge, Enfield Chase, was placed second, and Mr. S. F. Staffurth third. Class 12 was for six bunches of Incomparabilis varieties, but there were only two exhibits. The Rev. T. Buncombe led off with Gloria Mundi, Chryseis, Whitewell, Mabel Cowan, and Princess Mary, followed by Mr. H. R. Darlington, Park House, Potters Bar, who must have been very close to the winner.

Mr. H. R. Darlington had a walkover in the class for six vases of Poeticus, and was deservedly awarded first prize, Ibis, Virgil, and Horace being prominent. The same exhibitor won the first prize for six Tazetta varieties, under the same conditions as in the last class; while he led off again for three bunches of double varieties, followed by Mr. W. B. Cranfield.

United Horticultural Benefit and Provident Society.

The annual meeting of this society was adjourned on Monday, April 14, as, owing to some little delay in connection with matters concerning the new State side of the society's affairs, it was not possible to present the fully-audited accounts.

Members will be promptly notified of the date of the adjourned meeting, and a large attendance is hoped for on that occasion, as the late secretary, Mr. Collins, will be then presented with a handsome token of the respect in which he is held by all members.

The Nurserymen, Market Gardeners', and General Hailstorm Insurance Corporation, Lim.—The eighteenth annual general meeting of shareholders of this company was held on Friday, the 4th inst., at the registered offices, 41 and 42 King Street, Covent Garden. The Chairman, Sir Harry J. Veitch, presided, and reported that during the year the company had received five claims for 212 glasshouses damaged. In one nursery 93 out of 100 glass-houses were affected. The income from premiums amounted to £2,579, less bonus of 15 per cent. to the assured, £387 11s. 7d., giving a net premium income of £2,191 17s. 1d. The amount received from interest and ground rents amounted to £962 19s. 7d. A dividend of 1s. 6d. and a bonus of 6d. per share, free of income tax, was declared. £1,300 was added to reserve fund, making the reserves £20,500, and the balance carried forward. Messrs. Robert Piper, Joseph Rochford, Edmund Rochford, and William Sams were re-elected directors.

ANSWERS TO CORRESPONDENTS.

SCALE INSECTS ON CRAB APPLE.—J. F. C., Croydon: Will you please tell me what the enclosed specimens are? I scraped them from the stems of a crab apple tree. If they are injurious insects kindly tell me how to get rid of them.—The insects sent were examples of the Mussel Scale (Lepidosaphes ulmi). This pest is sometimes found in large quantities on apples and pears, and as it sucks the sap of the tree it proves injurious, and, in addition, if the infestation is a severe one, then the fruits may be attacked as well as the branches. It is too late to take the best measures for eradicating the pest, such as spraying with caustic alkali wash or with a mixture of lime, salt, and sulphur, but you may improve matters by carefully scraping the stems without injuring the tree, and following this with an application of a tobacco, sulphur, and soft soap solution; this should be applied by means of a stiff paint brush. Boil 1lb. of tobacco paper in a half-gallon of water until the nicotine has been extracted; strain and add an ounce of soft soap and four ounces of sulphur, and then add hot water to make up one gallon of solution. If this mixture is used warm and applied at once to the main stems and branches, the tree will be greatly relieved, and further measures may be taken next winter.

IMPROVING A LAWN.—L., Henley: Will you please tell me how best to treat a lawn that is mossy, and of poor appearance? The soil is gravelly in some parts, and chalky in others, but the turf is poor all over. I have been advised to dress the lawn with a mixture of sulphate of ammonia, kainit, and superphosphate; would this be a good plan, and what proportions should be used? Any advice given will be greatly appreciated, but I am afraid I cannot do much until autumn.—Mix old potting-soil with old decayed hot-bed or mushroom-bed manure, at the rate of two parts of the former to one of the latter, and pass the whole through a quarter-inch mesh sieve. First mow the lawn closely, then rake out the moss with iron rakes, and apply the soil and manure mixture at the rate

of about a barrowload to every six or eight square yards. As soon as this has been spread carefully apply three pounds of bone superphosphate per square rod. Work over the whole lawn with the back of a rake, so as to work the new material well down to the grass roots. Write us again next August with respect to autumn treatment.

STANDARD PLANTS OF SPARMANNIA AFRICANA.—L. G., Northampton: Kindly tell me the best and quickest method of growing Sparmannia africana as a standard plant. —Insert cuttings at once in sandy soil in gentle heat. Place them singly in small pots, and as soon as rooted pot them in rich light soil and keep them in a warm greenhouse where the conditions are suitable for quick growth. Allow the plants to grow straight away; do not pinch out the growing point, but suppress any side growths that may appear. Pot as necessary, and see that there is no check either from lack of moisture or root room. When the stems have reached the desired height pinch out the growing point, and subsequently pinch out the points of the other growths that form, so as to provide the foundation for a good head. Fuchsias, pelargoniums, heliotrope, etc., are all treated in similar fashion for the production of standard plants, but the general practice is to start with cuttings at the end of the summer or in early autumn, and keep the plants growing quite steadily through the winter; early in the year when growth becomes active it is not difficult to obtain quite good standards in this way.

YELLOW CARPETING PLANT.—F. B. S., Chepstow: I am in want of a good low-growing yellow plant for carpeting a large bed during the summer time, and am rather at a loss to know what to use. If you will kindly suggest likely subjects in your next issue I shall be greatly obliged.—The field for choice is not a wide one. There are yellow-flowered violas and violettas, and probably these will prove most useful provided the taller plants in the bed are not placed too closely together or are of a dense, spreading habit. A good form of the golden pyrethrum is not without merit, but it loses colour in the shade. Lysimachia Nummularia aurea, the yellow-leaved form of the common Creeping Jenny, is a suitable plant, and keeps almost flat upon the ground.

NAMES OF PLANTS.

L. W., Newport.—Sibthorpia europæa variegata.

B. D., Filey.—1, Cochlioda vulcanica; 2, Trichopilia suavis; 3, Strelitzia regina.

K. R., Ruislip.—1, Chamæpeuce diacantha; 2, Brassica caudata; 3, Leucojum vernum.

P. S. C., Grantham.—1, Dossinia marmorata; 2, Nidularium cyaneum; 3, Tulipa Clusiana; 4, Quercus Ilex variegata.

S. M. E., Petersfield.—1, Erica carnea; 2, Todea superba; 3, Selaginella apoda; 4, Forsythia intermedia; 5, Kerria japonica fl. pl.

T. F., Sherborne.—1, Thuia orientalis aurea; 2, Thymus serpyllum vulgaris; 3, Raphiolepis indica; 4, not recognised; 5, Prunus triloba; 6, Lonchitis pubescens.

GARDENING ENGAGEMENTS.

Mr. Walter John Dowson, M.A., has been appointed, on the recommendation of Kew, Mycologist in the East Africa Protectorate.

Mr. Louis F. Ruse, a member of the gardening staff of the Royal Gardens, Kew, has been appointed a probationer gardener for service in India.

Mr. J. Blakemore, who has been foreman during the past six years at Blyth Hall Gardens, Rotherham, has been appointed gardener at Avon Castle, Ringwood, the seat of the Earl of Egmont.

Mr. F. Utting, some years gardener at Wyaston Grove, Ashbourne, has been appointed gardener to J. R. Starkey, Esq., M.P., Norwood Park, Southwell, Notts.

Mr. H. J. Salloway has been appointed head gardener to the Countess of Cadogan, Deene Park, Wansford, Northamptonshire.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Town Trees.

The importance of trees in relation to town life is so great that the characteristic growth of the several kinds should be well known, and their adaptability to the various positions usually available in towns for their culture be fully understood by those more or less concerned with open spaces and street planting within town areas. Those who base their opinions on superficial observation may perhaps regard the statement of this proposition as superfluous; but, for evidence that this is not the case, it is only necessary to carefully observe what is being done in some of the urban open spaces. Within recent years considerable improvement has been effected in the methods of dealing with town trees, and where the open spaces are under the charge of men who have had a horticultural training there is usually but little of which complaint could well be made. In the smaller towns where there is no proper gardening staff a different state of things frequently obtain, and the trees are less satisfactory than could be desired. In some instances the trees have not been selected with due regard to the positions they occupy, and in others the management is weak, more especially with respect to the all-important details of pruning, which annually gives rise to much criticism. It would be well if an allround improvement of the knowledge of town trees could be made for the purpose of enabling those to whom the care of such trees are entrusted avoiding serious mistakes, and of placing those who have a penchant for indulging in criticism to know when it may properly be made. One point on which further enlightenment is desirable is the selection of trees. We are in full agreement with Cowper that "No tree in all the grove but has its charms," but the planter should first consider, in making a selection, the question of suitability with which the poet was in no way concerned. He has no occasion to seriously consider the statement made by Cowper, but it is essential he should select trees that possess such charms as will be displayed to the best advantage in the positions they are to occupy, and will also be in harmony with the environment. Hitherto, when selecting trees for town planting, attention has almost exclusively been given to forest trees that, under fairly favourable conditions, attain to a very large size. The two favourite trees have long been the lime and the plane, and they still enjoy a high degree of popularity. Their capacity for resisting the effects of atmospheric impurities is a strong point in their favour, and the tender green of the one and the rich verdure of the other are so pleasing as to have contributed in no small degree to the popularity they enjoy. While fully recognising the merits of these trees, which are so noble in aspect as to at once compel admiration when growing in park or woodland, it appears necessary to point out that when planted in the streets they can only be kept within bounds by an annual pruning of some severity. If the pruning is done by an expert who is fully conversant with the habit of the trees they are presentable, but when carried out by someone not skilled in the use of the pruning knife the appearance presented by them is far from pleasing, and of these there are very large numbers in our towns. We suggest that, instead of planting these two trees to the exclusion almost of all the other kinds that thrive in towns, some of the trees of more moderate growth might be selected with advantage. Certain of the robinias are, for example, excellent for towns, and there is perhaps no finer tree for street planting than the Scarlet Chestnut, which is seldom utilised in beautifying towns, although largely planted on the Continent for that purpose. This and other trees of moderate growth and great beauty are neglected, probably because of the belief more or less prevalent that selections for planting in both large and small towns should be made on precisely the same lines, and those only possessing the power of resisting the effects of the most deleterious impurities of the atmosphere be planted. This is a mistake that should be avoided, for its effect is to banish many beautiful trees that will grow as satisfactorily in towns of moderate size as in the open country. There is yet another point that is well deserving of consideration, and that is the difference in the time at which individuals of the same kind commence to make new growth. The planes show but little variation in this respect, but among the limes and horse chestnuts there is a difference in the time of leafing ranging from two or three days to a fortnight. The desirability of uniformity in the time of the leafing of trees forming avenues or long lines as in streets can hardly be questioned, but those who may be disposed to do so should carefully observe the lime trees in the same street from early in the spring. In the course of their observation they will see that some of the trees are well in leaf before the others have burst their buds, and they will notice that the early trees receive considerable injury should a severe frost be experienced. Should the observations be continued into the summer it will be observed that those trees which commenced to grow early will be the first to show "the sere and yellow leaf." If the limes and the horse chestnuts were to be sorted out according to the time of leafing, warm, sheltered towns might, if it was desired to enjoy the tender green leafage as early in the season as possible, be planted with those commencing to grow at an early

MR. W. A. WATTS.

period. On the other hand, in towns fully exposed to the effects of frosts and easterly winds, the trees making their growth at a later period could be planted, and injury to the young growth be thus avoided.

Mr. W. A. Watts, who for some years past has occupied a prominent position among those who devote attention to the cultivation and raising of daffodils, is a solicitor by profession, but about fifteen years since he commenced gardening as a hobby, and subsequently gave up his legal practice. Commencing with border carnations, he achieved much success with these fragrant flowers, winning medals and other prizes at Westminster, Birmingham, Shrewsbury, and several other of the principal centres. One year he was first in the open class at Shrewsbury, and was awarded four first-class certificates for new varieties. In the raising of new forms Mr. Watts has constantly kept in view the importance of a robust habit and good stems. Mrs. Harley, a blush-pink flower, The Master, bright crimson, Otter, Pied Piper, two yellow grounds, and W. A. Watts, rose-pink, are considered the best of the varieties he has raised. Mr. Watts has done some good work among the primroses and polyanthuses, and the success of his efforts has brought him numerous medals and prizes and some certificates. The daffodils are, however,the favourite flowers of Mr. Watts, and by perseverance along well-devised lines he has succeeded in raising a number of varieties possessing a high degree of excellence, among them being Aled, Brenig, Idwel, and Sindal. Recognising the importance of daffodils as garden flowers, Mr. Watts is a strong advocate for the encouragement of the strong-growing varieties, and consequently endeavours to select from his seed-bed such varieties, knowing something of the disappointment that is felt when varieties bearing flowers of great beauty are lacking in constitutional vigour. Mr. Watts is interested in tulips and some other bulbs, and, as in the case of daffodils, these are grown with much success by him at St. Asaph.

Fighting the Woolly Aphis.—One of the most destructive of the pests with which fruit growers have to contend is the Woolly Aphis, and the difficulty in dealing with it is greatly accentuated by the fact that the roots as well as the stems of the trees are attacked. Recognising the importance of keeping the roots as well as the branches of trees free from the Woolly Aphis, Messrs. Chivers and Sons, of Histon, near Cambridge, have adopted a plan of fighting the pest, which it is believed, will prove highly successful. A solution of carbon bisulphide is injected into the ground around the tree at several places about two feet from the trunk. This preparation gives off fumes that kill the insects and destroy the eggs. It was used successfully in France when the Phylloxera was devastating the vineyards, but its adoption in this country by Messrs. Chivers over several acres of their fruit plantations is the first attempt to use it on a large scale in connection with apple culture.

Ghent Quinquennial Exhibition.—This great horticultural exhibition will be opened on Saturday, April 26, by the King and Queen of the Belgians. The wonderful new building in which the major part of the floral display will be made has been built at a huge expense, and will form a permanent souvenir of the great Universal Exposition now being held in this famous horticultural centre. The main hall is about four acres in extent, and there are two annexes, each occupying two and a-half acres. Orchids, rhododendrons, azaleas, palms, stove plants, new plants, lilies, and tulips will be important features of the show, but the general arrangement promises to be the great thing, and even finer than anything Ghent has yet achieved in this direction. The jurors are drawn from almost every European country, and include a considerable number of horticulturists from Great Britain. We shall give a full account, with illustrations, of this magnificent exhibition in our issue of May 3.

Daffodils at Eaton Hall.—The Duke of Westminster very generously threw open the beautiful grounds at Eaton Hall to the public on Friday and Saturday last, so that the glorious display of daffodils, in beds, borders, and woodlands, produced by Mr. N. F. Barnes, might be enjoyed by the residents of Chester and neighbourhood.

Experiment Station for Cheshunt.—The Education Committee of the Herts County Council are now engaged in considering a scheme for establishing an experimental station at Cheshunt in connection with the market gardening industry which occupies so important a position in the parish. The work at the station will be devoted chiefly to investigations in soil sterilisation and other matters of immediate importance to those engaged in the cultivation of useful crops and ornamental plants under glass. The question of establishing an experiment station at Cheshunt is the outcome of a suggestion made by Dr. E. J. Russell, the director of the Rothamsted Experiment Station, who has done so much in assisting the growers in the solution of several of the problems associated with market gardening under glass.

International Flower Show at New York.—It is now considered that this great exhibition will be a financial success. From a purely horticultural point of view, it lost a good deal in effect from the fact that the exhibits had to be arranged on several floors of a huge building. Nowithstanding the great efforts of Messrs. C. H. Totty, W. Duckham, and H. Bunyard, the great show was hardly so imposing as was anticipated, not a few competitors dropping out at the last moment. Cut roses and carnations were the prime features of the display. Sir Jeremiah Colman's odontioda created a sensation. Liliums were also fine. Mr. W. A. Manda secured practically all the awards for new plants. Matchless is the new carnation par excellence, and it was awarded our own Perpetual-flowering Carnation Society's gold medal; it is a very fragrant white variety. The Britishers present have had a great time, and Mr. W. Wells (Merstham) considers that it would occupy him for the rest of the year if he accepted all the invitations he has received. Mr. Stuart Low (Enfield) was present, and acted as one of the judges of orchids.

A Spring Rose Show will be held at the Royal Horticultural Hall on Thursday, May 1, by the National Rose Society. This is the society's first spring exhibition, and twenty-seven classes, with liberal prizes, have been provided. The promise for a fine display is excellent.

Testimonial to Mr. E. Viner.—Mr. Viner (a working man), of Frome, Somerset, the raiser of one of the forms of Countess Spencer sweet pea in 1901, has since become an invalid, and unable to earn his living. An influential committee of members of the National Sweet Pea Society promoted a testimonial to him, and Mr. Cuthbertson, of Edinburgh, who has acted as treasurer, reports that the actual amount subscribed was £76 6s.: the outlay for printing and postages, £7 16s. 8d., leaving a free balance of £68 9s. 4d. Two or three friends subscribed an additional £1 10s. 8d. to enable him, in the name of the subscribers, to present Mr. Viner with £70, which he has most gratefully acknowledged. There were 106 subscribers, all parts of Great Britain being represented in the list, as well as Germany, the United States, South America, and South Africa, the amounts ranging from £10, given by the National Sweet Pea Society, down to two 3d. subscriptions from employees on the Shelley Sweet Pea Farm.

Purchase of the Crystal Palace.—The question of the purchase of the Crystal Palace and grounds for the general public came before the General Purposes Committee of the London County Council a few days ago, and this committee decided to recommend the Council, under certain conditions to make a grant of £50,000. We may add that the whole question was raised in connection with the Lord Mayor's appeals for funds to secure the Crystal Palace.

The Late Mr. William Bennett, who was head gardener at Rangemore, Burton-on-Trent, for forty-five years, to the late Lord Burton and the Dowager Lady Burton, left £5,440.

City of London Rose Society.—This society, as our readers are aware, has been formed to foster and increase the love of the rose and of rose growing amongst City workers, who stand most in need of the freshening influence and beneficial relaxation that the exercise of such a hobby affords. The schedule of classes and prizes for the first exhibition, to be held at Cannon Street Hotel, on June 26, has been issued, and we find that it has been modelled on N.R.S. lines, competitors being grouped according to the number of plants they grow. There are classes for nurserymen and for ladies, as well as for the rank and file, and there are cups and pieces of plate galore, as well as cash prizes. Mr. A. E. Protheroe, 67, 68, Cheapside, is the secretary of the society.

Royal Botanic Society's New Treasurer.—At a meeting of the Fellows of this society it was announced that Sir William Dunn had been elected treasurer in the place of the late Mr. C. Brinsley Marley. Sixteen new Fellows were elected, and the names of 120 candidates for election at the next meeting were read.

Suffragette Outrage at Handsworth Park, Birmingham.—A partly successful effort to destroy the boathouse in Victoria Park, Handsworth, Birmingham, was made during the night of April 21, or early on April 22, presumably by Suffragettes. Fire lighters and paraffin were freely used over the boat cushions, but these did not blaze much, consequently though boats, cushions, etc., were so badly damaged as to be useless, the damage to the boathouse itself was very slight. Victoria Park is one of the many fine public parks belonging to the City of Birmingham.

Economic Aspects of Ornithology.—An exhibition of interest to botanists, entomologists, and ornithologists will be held from May 3 to June 1 in the Palace des Beaux-Arts at Liege. The object of the exhibition is to illustrate the economic aspects of ornithology, and will be based on treatises relating thereto, and will include collections of birds, insects, and such plants as yield by means of their seeds a large proportion of the food of birds.

MIDLAND DAFFODIL SHOW.

Fine weather is a great asset to any society, and such an asset the Midland Daffodil Society had on Tuesday, when its daffodil show was opened at the Edgbaston Botanic Gardens. The gardens themselves, thanks to Mr. Humphreys, were bright with daffodils and tulips, and the rock garden in bloom with its primulas, aubrietias, and other spring flowers, while in the houses cinerarias, orchids, etc., were gay. Visitors came in goodly numbers, and the daffodil specialists were present in great force, some coming from the end of Cornwall, and others from Scotland, while old Mr. Van Waveren, despite his 86 years, came over from Holland, and Mr. Manger came from Guernsey, all bringing or looking for new varieties.

Birmingham Show is a regular Mecca of the fanciers, and it is the last of the daffodil shows where flowers are seen in quantity. On this occasion the competition was splendidly keen, and, on the whole, the flowers were in fine condition. Mr. Crosfield, Mr. P. D. Williams, Mr. A. M. Wilson, Mr. W. T. Ware, Rev. G. H. Engleheart, Mr. Bourne, Messrs. Barr and Sons, Messrs. J. D. Pearson and Sons, Robert Sydenham Limited, and Messrs. Cartwright and Goodwin, all had novelties, and a large amount of business was done in these new things.

Mr. Robert Sydenham, generous as ever, dispensed a hospitality that was greatly appreciated, and which made the wheels of business run easily, while Mr. H. Smith, the secretary of the society, made his usual complete arrangements for everyone concerned.

OPEN CLASSES.

It is no easy matter to find good blooms of fifty varieties of daffodils, fairly representing the various sections, at this date, but six competitors did so, and premier position was awarded to the Rev. J. Jacob, Whitewell Rectory, Whitchurch, Salop. His flowers were very fresh, and in excellent variety as regards form and colour. Conspicuously good were Will Scarlet, Incognita, The Doctor, Whitewell, Florence Pearson, Horace, Heroine, Bernardino, The Fawn, Lorna Doone, Coreen, Queen Alexandra and Weardale Perfection. Second prize fell to Messrs. Cartwright and Goodwin, Kidderminster, for a fine set, Mr. C. Bourne, Bletchley, coming third.

Five exhibitors came forward in the class for six yellow trumpet daffodils, three flowers of each, and here Mr. W. A. Watts, St. Asaph, led with bold blooms of Monarch, Magog, and seedlings; Rev. J. Jacob second with King Alfred, Cleopatra, etc.; and Mr. W. A. Milner, Totley Hall, Sheffield, third. Mr. W. A. Watts led for six white trumpets with Mrs. Betteridge, Cyclen, Mdme. de Graaf, Beren, Glaslyn, and a seedling; Mr. J. Mallender, Bawtry, second. In this class Mr. Brodie, of Brodie, and Mr. C. L. Adams presented a special piece of plate as the first prize.

In the bicolor class for six trumpet daffodils, three flowers of each, there were four entries, and Mr. W. A. Watts was first again, showing noble flowers of Adwel, Golden, Arwin, Bangor, Weardale Perfection, and Cethin; Rev. J. Jacob second; and Mr. J. Mallender third.

Mr. Watts was again to the front in the class for six incomparabilis varieties, and here he showed Homespun, Lemon Queen, Pyrie, and some of his own seedlings; Rev. J. Jacob second. For bicolor incomparabilis the Rev. J. Jacob came to the front, and he had Bernardino and Whitewell in splendid form; Mr. C. Bourne second, and Mr. W. A. Watts third.

Mr. Watts came again in the class for Barri varieties, and here his Occident, Beacon, and Torchlight were good; Rev. J. Jacob second.

For six white perianthed Barri varieties, the premier prize fell to Mr. C. Bourne, Bletchley, who showed Bullfinch, Ethelbert, Cossack, Rev. Eve, and Snowbird; Mr. F. Herbert Chapman, Rye, second, and Rev. J. Jacob third; five entries. Lady Moore in Mr. Jacob's set, was very attractive by reason of its wide orange-rimmed crown.

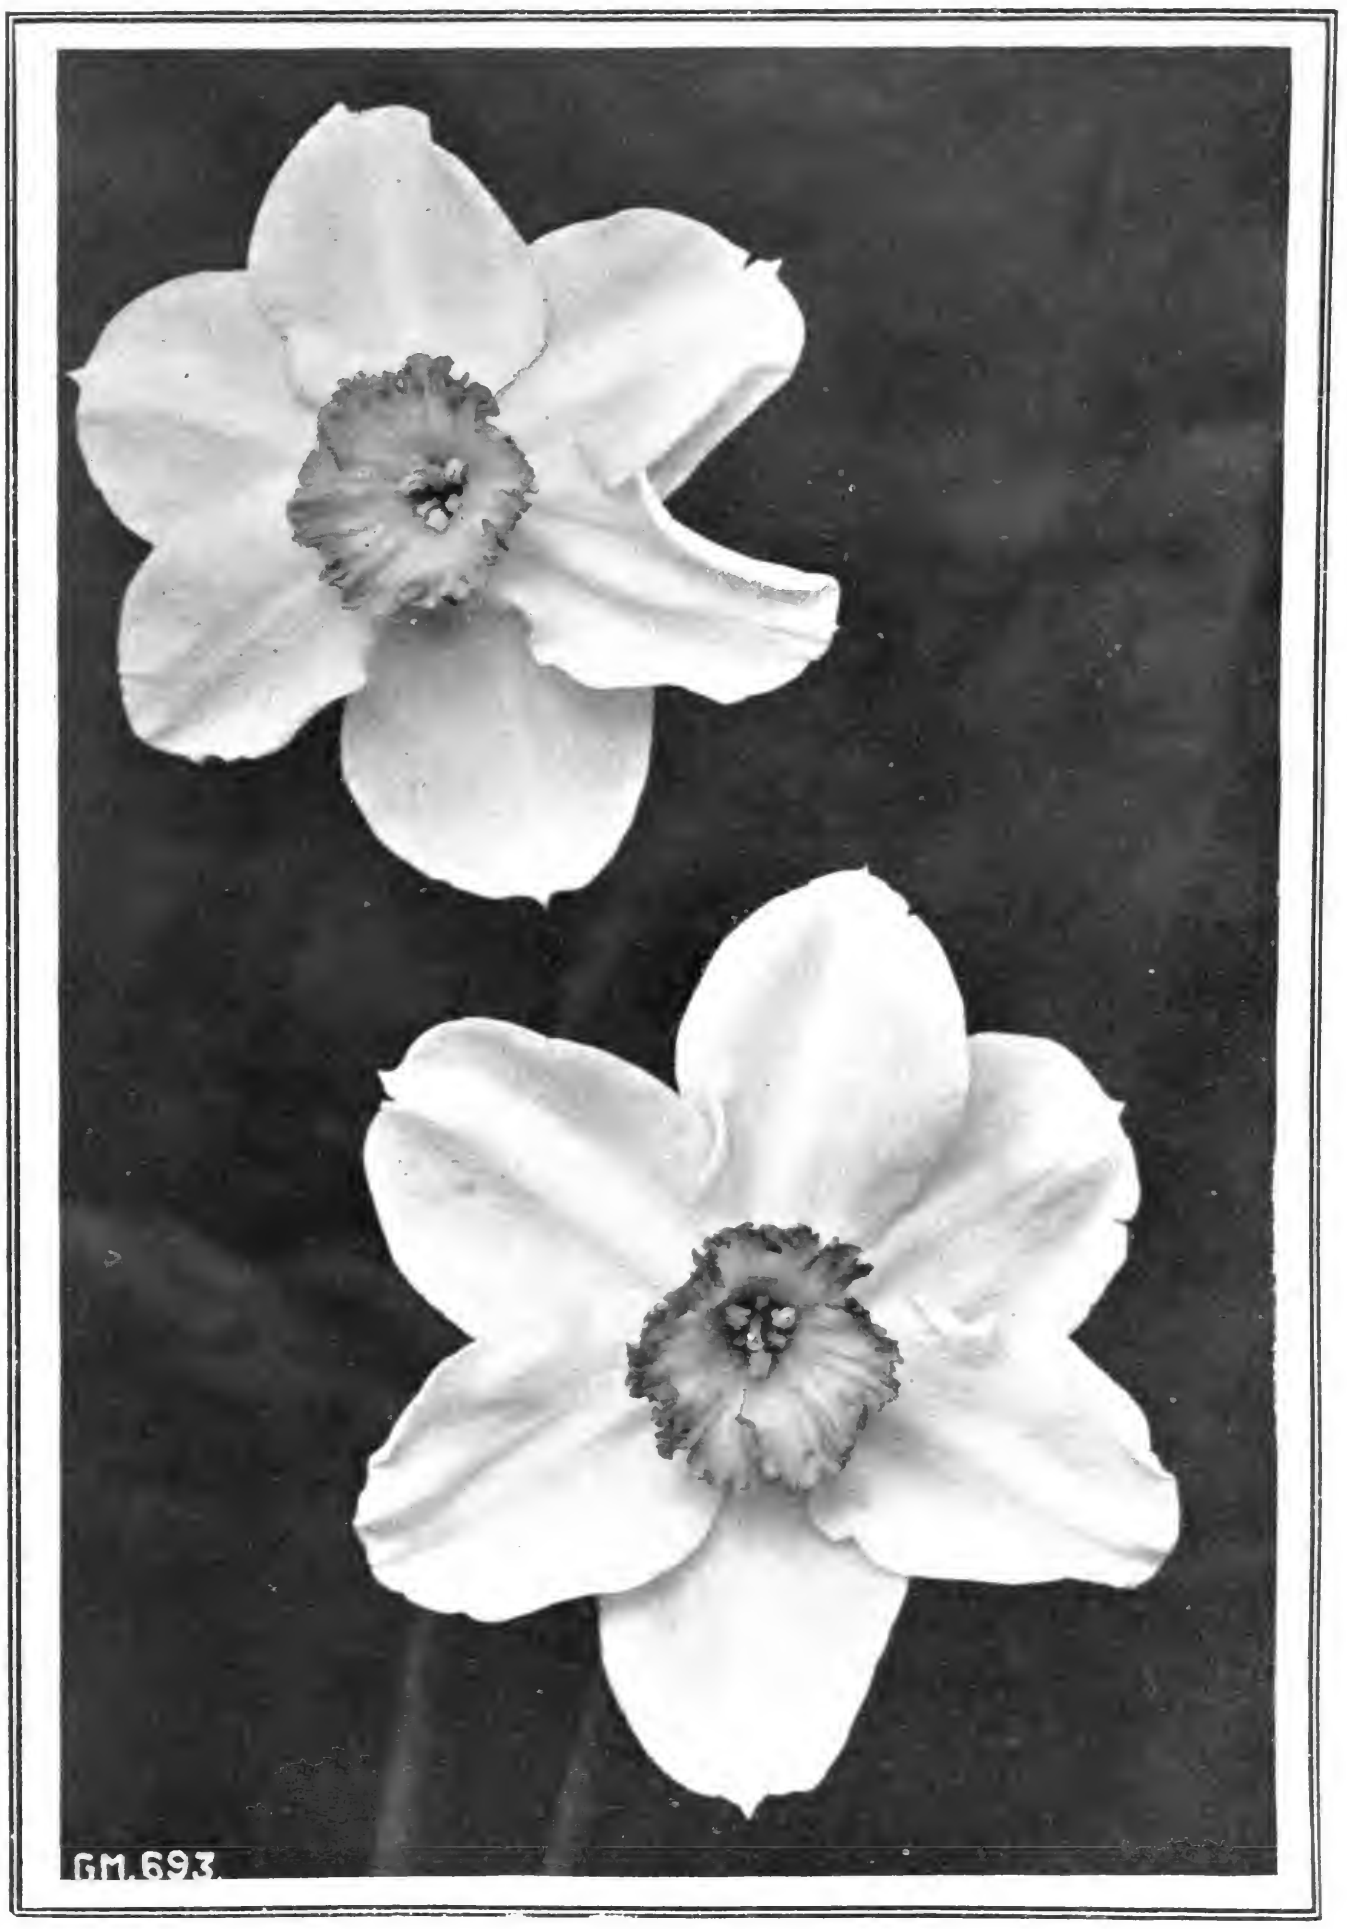
In the Leedsi class, twelve varieties were asked for, and here the Rev. J. Jacob scored, his best blooms being of Hon. Mrs. Franklin, Endurance, Evangeline, Lord Kitchener, Matthew Henry, and H. C. Bowles; Mr. C. Bourne second; two entries were disqualified for showing Barri varieties. Mr. Watts had the best three triandrus hybrids, and both Dewis and Cibyn were charming; Messrs. Cartwright and Goodwin second, their Cairngorm being a notable variety. The latter firm won first prize for tazetta and tazetta hybrids with bunches of Irene, Orent, Ideal, Jaune à Merveille, Elvira, and Klondyke.

The class for nine poeticus varieties brought out five entries, and made a pretty display. Mr. C. Bourne was placed first for George Herbert, Barcarolle, Virgil, Homer, Stephen Phillips, Lullaby, Orange King, Laureate, and Horace—a fine set; Messrs. Cartwright and Goodwin second, and Mr. F. Herbert Chapman third.

Mr. C. Bourne, Bletchley, was easily first for a decorative exhibit of daffodils, with vases and baskets of poeticus, Leedsi, and Barri varieties associated with ferns; Mr. J. Pope, King's Norton, second; and Rev. J. Jacob third, the latter spoiling his display by the use of dry moss among his flowers.

In the single bloom classes Mr. Hawker, Ivybridge, had the best poeticus flower in Dulcimer; the best double flower was Golden Rose, from Mr. J. Pope; Mr. P. D. Williams had the best Jonquilla hybrid—a seedling; Mr. Ridley, Wincanton, had the best single Leedsi flower, a fine Moonbeam; Queen of Hearts secured a first prize for Mr. Bourne in the Barri section; Mr. Welchman's The Commonwealth was the best yellow trumpet; Mr. A. M. Wilson's White Knight the best white trumpet, and Mr. Wilson's "P.B.F." the finest bloom of a bicolor trumpet variety.

Only one entry for a dozen species or varieties of species was filled, and this, from Mr. R. Bruce Watts, Harborne, was awarded a second prize; he showed N. gracilis, N. Macleai, N. abeissus, N. moschatus (of Haworth), N. triandrus albus, N. Santa Maria, N. tenuior, N. odorus campernelle, N. Queen of



NARCISSUS TINSEL.

A beautiful Barri variety, with pure white perianth segments and yellow cup, exhibited by Robert Sydenham Limited at the Midland Daffodil Show.

Spain, N. princeps, N. maximus, and N. biflorus.

SEEDLINGS AND NEW VARIETIES.

The Bourne Daffodil Cup, offered for the best dozen daffodils raised by the exhibitor, was won by Mr. Ernest Crosfield, Cossington, Bridgwater, with exquisite varieties, chiefly Barri and Poeticus sorts; some were numbered, but Dell, white with neat soft yellow crown; Winsome, orange crown; Ring Dove, a neat eyed poet with crimson edge and yellow crown; Nomad, the fine Touchstone, and Orb were the finest of the named sorts. Mr. W. Welchman, Upwell, Wisbech, came second with trumpet varieties, Hereward and Clodia being among his best. For half a dozen seedlings, not in commerce, and raised by the exhibitor, Mr. A. Wilson, Shovell, Bridgwater, led with unnamed varieties, but his No. 51 and 191 were lovely, neat flowers, with rich-hued crowns; Mr. W. A. Watts second; and Mr. J. Pope, King's Norton, third.

For three varieties under similar conditions, Mr. P. D. Williams, St. Keverne, Cornwall, scored with lovely flowers, his Susan, white, with small cream crown and green centre was a delightfully cool flower; while No. 795, with a salmon-pink shading running well into the perianth segments, was a great advance; ten entries. Messrs. Cartwright and Goodwin second; and Mr. C. H. Cave, Margotsfield, third.

The Novice Seedling Challenge Cup, open to raisers who have never before won a prize for seedlings was awarded to Mr. N. Y. Lower, Presteign, with unnamed flowers, but the fine, clear orange crown of 86 was much admired; Mr. C. L. Adams, Kidderminster, second; and Mr. W. Wilson, jun., Holmesfield, Sheffield, third; eleven entries.

A grand set of twelve daffodils not in commerce for more than four years, won for Mr. E. Crosfield the Cartwright Cup in fine style; he showed superb blooms of Winsome, Orb, Flattery, Cæsar, Anchorite, Sarchedon, Noblesse, Ring Dove, Touchstone, Dick Turpin, Dell, and Snow King, and every flower was in superb form; Messrs. Cartwright and Goodwin second.

Mr. C. Bourne scored for six varieties that have not been in commerce more than four years, and he did so with Miss Willmott, Black Prince, Evensong, Lemon Belle, Queen of Hearts, and Giraffe; Rev. J. Jacob, Whitewell, Whitchurch, second, and Mr. H. D. Phillips third. Mr. H. G. Hawker, Ivybridge, Devon, led for three varieties with Orange Ring, Crimson Comet, and Dulcimer; Rev. T. Buncombe, Black Torrington, Devon, second; and Mr. F. H. Chapman, Rye, third.

Mr. Crosfield obtained the Herbert Chapman Trophy for six poeticus daffodils that have not been in commerce more than four years, and he displayed beautiful examples of Sarchedon, Nellie Price, Madrigal, Cæsar, Snow King, and Ring Dove; Mr. A. M. Wilson a close second and Mr. C. Bourne third; four entries. The Walter Ware Cup for a dozen varieties of triandrus hybrids fell to Mr. W. A. Watts.

AMATEURS.

Premier award for six varieties, any division, that have not been in commerce for more than four years, was won by Mr. N. Y. Lower, with good examples of Giraffe, Snow King, and some seedlings; Rev. T. Buncombe second; and Mr. T. Batson, Beaworthy, third. The best collection of two dozen varieties came from Mr. E. H. Ward, Ludlow.

Mr. T. Batson was first for three Barri varieties, with Rosa Bedford, Harold Finn, and Greeneye; Mr. N. Y. Lower second; seven entries. Mr. Lower was first for six Leedsi daffodils, his White Lady and Evangeline being especially good; Mr. E. H. Wood, Ludlow, second; six entries. Four came forward in the class for three tazetta varieties or hybrids. Mr. J. A. Kenrick, Harborne, leading with Jaune a Merveille, Aspasia, and Klondyke.

Mr. E. H. Wood had the best six poeticus varieties, and Mr. Lower was a capital second, among four competitors. Mr. Gumbleton, Tewkesbury, was first for three double sorts with Golden Rose, Primrose Perfection, and Codlins and Cream; Mr. R. Bruce, Waite, second.

For a dozen varieties of daffodils, not to cost more than 5s. per dozen bulbs, Mr. A. Taylor, Olton, led with Glory of Leiden, Katherine Spurrell, White Lady, Emperor, Leonie, Mdme. de Graaff, Barri conspicuus, Seagull, Homer, Crown Prince, Nelsoni aurantius, and Princess Mary; Mr. R. Bruce Waite second, and Mr. J. A. Kenrick third. Mrs. Ridley, Wincanton; Mr. W. T. Mitchell, Leek Wootton, Warwick, won prizes in classes open to those who have not won three first prizes previously.

In the remaining classes Mr. E. Deakin, Mr. A. Taylor, Mrs. Ridley, Mr. W. F. Mitchell, Mr. G. Stocks, Doncaster; and Mr. E. Winchester, Rubery, Birmingham, won leading awards.

Mr. J. A. Kenrick had the best pots of Dutch and of Darwin tulips, and of tazetta narcissi, and he also scored for cut tulips. Mr. S. Mortimer won first prize for four baskets of polyanthuses.

Mrs. A. M. Macdonald, Harborne, scored for a table of daffodils, with Barri conspicuus and Japanese maple foliage; Mr. E. Deakin, Hay Hall, Hay Mills, second.

NON-COMPETITIVE.

Across the end of the lower hall Messrs. Barr and Sons, Covent Garden, put up a display that was worthy of their name and fame. The flowers were good and well set up. Of the newer daffodils on view, Zuave, with broad, wide, orange-rimmed crown; Sunrise, creamy-white, with bright yellow crown; Red Beacon, a fine Barri, with orange crown; St. Olaf, certificated in London last week; Mrs. G. H. Barr, one of the best white trumpets; Snow King, a very pure and solid poeticus form; Fiona, with very big, straight cream-yellow trumpet; and Primrose Phœnix, one of the best of the double daffodils. Altogether there were about a hundred and forty varieties in this group. Messrs. Walter T. Ware, Lim., Bath, put up a lot of new things, many of them unnamed, but Flounce, a broad, flat-crowned Barri, with glorious, frilled, orange and orange-yellow crown, was the variety that every eye turned to instinctively. Mr. Vincent Slade, Taunton, submitted single and double pelargoniums, and his bunches of St. Louis, Pres. Baillet, Dagata, Burford, C. H. Curtis, and Mrs. G. Cadbury were dazzingly brilliant. He had also a grand and vivid crimson polyanthus on view, named Slade's Crimson Giant, a fine thing for spring bedding.

Robert Sydenham Limited, Tenby Street, Birmingham, exhibited both daffodils and tulips, but the former were most in evidence, and the flowers were delightfully fresh. Albatross, Ethelbert, Red Chief, Torch, Lulworth, the broad-crowned Orange Gem, Cornelia, and Stonechat were all excellently displayed, but the pick of the group was Tinsel, a lovely Barri variety with pure white perianth segments, and a charmingly frilled light yellow cup that is faintly tinted with orange round the rim. A quite large exhibit from Messrs. J. R. Pearson and Sons, Lowdham, Notts, contained a number of very fine flowers, notably of Chaucer, Crescent, the brilliant Cœur de Leon, the wonderfully broad-crowned Prima Donna, Heroine, Whitewell—a fine form, Crœsus, Priscilla, a giant Leedsi, Gipsy Queen, a new Barri variety, with soft creamy-yellow perianth, and large rich yellow, frilled crown that is stained with deep orange at the rim; Norah Pearson, and Elfrida Pearson were other good new things.

Banks of beautiful cinerarias, in blocks of various colours, were submitted by Messrs. Sutton and Sons, Reading; the rose-pink and the crimson varieties were especially fine. These banks were broken up by smaller displays of early vegetables, admirably arranged, and the subjects finely grown and most inviting. The Sutton rhubarb, early carrots and turnips, tomatoes, and peas attracted much attention. Mr. S. Mortimer, Farnham, was responsible for a pretty exhibit of perpetual carnations, but no less attractive were his several dozen flowering plants of All-the-Year-Round stock, a fragrant, white-flowered variety of high merit.

Mr. H. Ellison, West Bromwich, brought up a fine selection of the newer ferns, and arranged these around a central grouping of the graceful Phœnix Rœbelini, one of the very best of palms for home decoration. Messrs. R. H. Bath's exhibit was not an extensive one, but it contained beautiful blooms of the rich Refulgence, the wide-trumpeted Crystal Queen, the drooping Parnassus, and the Golden Buttercup daffodils, as well as of Argent, the double form, Evangeline, Whitewell, Miss Willmott, and Orangeman. The tulips, in bowls of fibre, from Wisbech, provided a great attraction, and as evidence of the lasting power of well-grown tulips, it may be noted that some of the bowls were shown at the Royal Horticultural Hall, the previous Tuesday.

A charming rock garden exhibit from Messrs. Bakers, Wolverhampton, produced a most pleasing effect. The bright saxifrage Red Admiral, and S. Bathonensis occupied a central position, while fine colonies of Primula cortusoides, Incarvillea grandiflora, Erinus hirsutus, Viola gracilis, the modest little Houstonia cœrulea, the beautiful white Ranunculus amplexicaule, Lychnis alpina, and Dianthus cæsius Baker's var. had each their special attraction.

The Rev. G. H. Engleheart, Dinton, Salisbury, again brought up a lovely lot of new seedling daffodils, all under number. No great daffodil show is complete without Mr. Engleheart and his novelties; every faucier crowds about them, and soon the varieties become distributed all over the country. The most talked about flower in Messrs. Cartwright and Goodwin's group was Emerald Eye, a Barri variety with pure satiny-white perianth, white-tinted crown, and beautiful green centre—a most delightful flower, chaste and exquisite.

Messrs. B. R. Cant and Sons, Colchester, contributed a beautiful lot of cut roses, and their stand of Fortune's Yellow was the central feature. Mr. C. Bourne, Bletchley, displayed daffodils and some capital tulips.

AWARDS OF MERIT.

Norah Pearson. — A refined trumpet variety, with fine upstanding flowers, perianth cream-white, trumpet clear soft yellow, frilled at the mouth; Messrs. J. R. Pearson and Sons, Lowdham.

Dulcimer.—A bold poeticus variety, with white perianth and neat orange and yellow crown; Mr. H. G. Hawker.

Kingdom.—A fine giant Leedsi with broad substantial white perianth, and a light yellow, well frilled, wide trumpet or large cup; Messrs. Walter T. Ware, Bath.

Cairngorm.—A very bold triandrus hybrid, light yellow, with a fairly large and broad, frilled trumpet; Messrs. Cartwright and Goodwin, Kidderminster.

Queen of Hearts.—A fine Barri variety figured in our columns last year. It has a soft yellow perianth, and bright orange cup; a very effective and pleasing flower; Mr. Christopher Bourne, Bletchley.

MEDALS.

Gold.—To Messrs. Barr and Sons, Covent Garden.

Silver-Gilt.—To Messrs. J. R. Pearson and Sons, Lowdham; to Robert Sydenham Limited, Birmingham; to Messrs. B. R. Cant and Sons, Colchester; to Messrs. Bakers, Wolverhampton; to Messrs. Cartwright and Goodwin, Kidderminster; to Mr. S. Mortimer, Farnham; to Messrs. Sutton and Sons, Reading.

Silver.—To Messrs. R. H. Bath, Lim., Wisbech; to Mr. Vincent Slade, Taunton; to Mr. H. N. Ellison, West Bromwich; to Mrs. R. O. Backhouse, Hereford; to Mr. C. Bourne, Bletchley; to Messrs. Walter T. Ware, Lim., Bath.

NEWER CACTUS DAHLIAS.

For some few years past we have heard constantly that the fate of the cactus dahlia is sealed, though up to the present there is little if any evidence of its decadence in popularity. On the contrary, while the raisers can keep us supplied with good novelties year after year, cactus dahlias are likely to be grown more than ever, and it is something new, something novel, that the exhibitors and fanciers are always looking out for. Then there is the ever-increasing army of garden lovers, who require their cactus dahlias solely for garden decoration, and the production of cut flowers. This section of growers, I fear, has in the past been somewhat neglected, for it was thought that what was good enough for exhibition purposes was equally good for the garden, and this has proved a stumbling block in the path of the dahlia's progress as a popular garden flower.

However, it is pleasing to note that great strides have been made in the right direction during the past four years, and it will undoubtedly be more manifest in the near future. It will certainly take time to educate the public up to the fact that they can grow exquisite cactus dahlias in their gardens that will produce flowers well above the foliage, and on long, stiff stems; in fact, I shall go so far as to prophesy that a decade hence a bad stem will be unknown among the cactus varieties, be they exhibition or garden sorts.

In these notes I am not concerned with cultural details, but I wish to deal with the newer varieties, as they are known to me. Those that are being distributed this spring I have only seen at the exhibitions last autumn, but those sent out in 1912 I have seen growing, and can form a better opinion of their merits, though it is quite

CACTUS DAHLIA DOLLY.

Flowers crimson-scarlet tipped with white. Raised by Messrs. J. Stredwick and Son.

impossible to judge the merits or otherwise of a dahlia with a single season's trial, especially such a cold, cheerless season as we had last year, which was quite unsuited to the proper growth and development of the dahlia.

Some of the best and most striking novelties for this spring are: Edith Carter, a beautiful flower, yellow, heavily suffused with bright rosy-carmine; F. W. Fellowes, a very large flower, with long, straight florets, and a good, high filbert centre, bright orange in colour; although it failed to obtain an award, it is, to my way of thinking, one of the finest novelties of the year; George Schofield, a much incurved form, yellow deepening to apricot (see illustration); Pegasus, a fine fancy form, with flowers of average size, white, with pink tips, striped and speckled with red; John Riding, an enormous flower, with long, incurving florets, a rich, deep crimson, a variety that should satisfy any exhibitor or fancier; Dolly, a beautiful bicolour flower, of remarkably good form, the colour crimson-scarlet, passing to white (see illustration); Mrs. Pearson, fawn, shaded pink, very refined flower; Sportsman, a scarlet variety that is very distinct and has a splendid stem.

Coming to the varieties that were sent out last spring, some of the most satisfactory were Esther, a soft and pleasing shade of rose-pink; Fulgent, a brilliant crimson, very striking; Fred Wenham, a rich pink and fawn variety with a salmon centre; Golden Wave, a rich deep yellow; John Woolman, scarlet, shaded rose; Mrs. Brandt, salmon-buff, shading to yellow in the centre; Miss Stredwick, soft yellow, heavily suffused pink; Miss Hills, reddish-bronze, overlaying salmon; Olympic, deep crimson self; Richard Box, clear light yellow; Uranus, white, striped scarlet, a good exhibition form; and Mrs. Stephens, pale primrose, very large.

No doubt many of the others are equally good, but the season was much against them, and I expect better results this coming season.

J. B. Riding.

MAGNOLIA SALICIFOLIA.

Professor Sargent, in his "Forest Flora of Japan," directs attention to this species, and describes how he and the late Mr. J. Veitch found it in 1892 growing on Mount Hakhoda. They were successful in obtaining seeds, and the plants raised from them were the forerunners of all which are now to be found in American and European gardens. The species is quite distinct from others previously grown, and it may be recognised by its narrow, deciduous leaves, which are often from four to five inches long, and have a peculiar habit of narrowing gradually to both ends. The glistening white flowers are fragrant, three and a half to four inches across, and composed of long, narrow petals. They appear in April or early May, but, so far, plants have not attained their best flowering age in this country.

The species is described as forming a slender tree, 15 to 20 feet high, in its native country, but here it appears likely to develop a bushy habit, with slender branches. Like other magnolias, it requires a moist rooting medium, and the most satisfactory results may be looked for by planting it in light, loamy soil containing a little peat. In Japan its best proportions are attained when it is growing in rich soil about the margins of streams, where the ground never becomes dry. From what can be seen of it at present, it is likely to prove almost as decorative as the well-known M. stellata.

W. Dallimore.

EXHIBITING AND JUDGING DAHLIAS.

(Continued from page 276.)

That some little excitement, some little feeling that one's lungs are not large enough to hold all the breath we would like to get into them, is pardonable, especially if competition is close and one's flowers are just as good, and in one's own estimation slightly better, than those of our fellow competitors, but, generally speaking, worry and excitement, if carried to excess, go a long way in damaging an exhibitor's chance of a prize.

Now let us suppose the flowers have been all arranged for weal or woe, and the work of the judges begins. How different the feelings, and often the manner, of a judge from those of an exhibitor. The latter has been driven out from amongst the exhibits like a dog out of a church, possibly by a big gentleman in blue wearing, under Britannia's hat, a haughty look and many buttons. Judges, on the other hand, flourishing pencil and book, pass this authority unchallenged and unharmed, and they proceed to pass judgment on the exhibits which for hours have been the object of much care, not a little expense, and much thought and expectancy.

The first efforts of judges should be to carefully find out how far the stands of the particular class being judged extend, where the division is, and to make sure there are no stands of this class on another table or round a corner. Each stand is then minutely looked through, and all blemishes carefully taken stock of, the characteristics of each stand noted and every point of it criticised, and it is surprising how often this scrutiny will totally alter the opinion which a first glance engenders, i.e., that there is very little to choose between them. Now the judges (and there should always be three of them) proceed collectively to eliminate those usually termed the "tail end," that is the worst stands, leaving only the three, or maybe four, which are to receive awards, and if any uncertainty occur as to the order of these, they should, whenever possible, be placed side by side, in order that the same light, the same surroundings and background, may influence each in the same way, for if this is not done, light, or possibly the want of it, may act unfairly towards some of them.

And now I come to the danger zone, for as yet there is not, in my opinion, as much guidance as there ought to be from the authorities of our National Society as to the value of the various good points found in dahlias when exhibited, but of this I will speak later on. The plan adopted now in most cases where stands run each other closely, is to allow a certain number of points, say five, as the utmost limit of an extremely good flower, or bunch, or vase, and to decrease these according to the estimated value of each flower or bunch as the judges collectively may determine, adding them up as the flowers of each stand are finished, and awarding the prize, of course, to the highest number of points.

This method may, and often does, answer fairly well, but I am strongly of opinion it does not go far enough, it does not go deep enough. Too much is left to the personal likes and dislikes of the judges, and if they happen to be, as in most cases they are, fewer than three, the danger of the judges' personal bias weighing in the balance is appreciably enhanced.

Now that the classes and sections of dahlias are multiplying year by year, this is more and more likely to show itself, and the bewilderment in a few years, both for exhibitors and judges alike, will give, unless we are careful, such a spirit of uncertainty to exhibitors, they will consider it so much a matter of chance, that fewer will sum up courage to show, and the interest in dahlia showing will decline.

Many will remember I called attention to this some ten years ago, and nothing that has occurred since has altered by opinion in the least in regard to it. An exhibitor is in justice entitled to know the value of the various good points in a dahlia, and if some day our society draws up a code of rules for judging dahlias, a guide, not only to ourselves, but also to the hundred and one horticultural societies up and down the country, where dahlias are judged by gentlemen's gardeners and others, whose acquaintance with the good points of a dahlia is more or less uncertain, I consider it will go a long way towards justifying its existence as a national authority for the encouragement of, and disseminating interest and information in dahlia culture.

If we turn to the directions given for dahlia judging in the Royal Horticultural Society's "Rules for Judging," it will be seen they advise—and I really think a paper I read on the subject before the R.H.S. many years ago suggested the idea—that points should be given to the several qualities of a flower. However, they direct that:

2 points should be given for good form.
2 ,, ,, for good centre.
2 ,, ,, for colour and freshness.
1 ,, ,, for size.

Now we have here four lines giving points to four good qualities in a dahlia, and I might as well say candidly, I disagree with three out of the four.

Let us take the top two first. They are, two points for good form and two for a good centre, and I ask did anyone ever see a dahlia of good form, worth two points, unless it had a good centre? These two, therefore, might just as well be amalgamated. Now we take the last, which directs that one point be given for size. Surely there are not many exhibitors of dahlias who would wish judges to follow this in its exactitude. I do not say size is the chief factor in a good dahlia, but surely size deserves more than one point out of seven.

The suggestion I made some years ago for judging dahlias of all classes was that each flower or bunch of flowers should be given by the judges—

4 points for good form.
3 points for good size.
2 points for colour and freedom from blemish.
1 point for setting up.

These would give ten points for each perfect specimen or bunch well set up, and they would be modified according to the value of each good quality in each separate flower or bunch.

The course I suggest would in some cases be unnecessary, for exhibits are not always so close in merit that the superiority of the one is not manifest without recourse to counting the points of each flower, but I refer to cases, and they are many, where competition is keen and the value of each exhibit not so apparent.

We have, for instance, no guide to tell us now if a stand, perfect in form but mediocre in size, should, or should not, be placed before one perfect in size but perhaps not so good in quality.

I cannot help thinking that if exhibitors, and especially amateur exhibitors, knew that judges judged by rule rather than by caprice or partiality for some one or other quality in the dahlia, it would create greater confidence and increase the number of dahlia exhibitors.

I had intended saying something in regard to judging new varieties for certificates, but I will content myself with saying I think decisions in this should be by ballot and not by show of hands.

The matters I have spoken of are well worth discussion, and if anything I have said or suggested tends to infuse new hopes and aspirations in dahlia growers who are not now dahlia exhibitors, let me promise them they will soon derive increased pleasure in dahlia culture, a more close attachment to and admiration for the Queen of Autumn, and let me wish them with all my heart success on the show day.

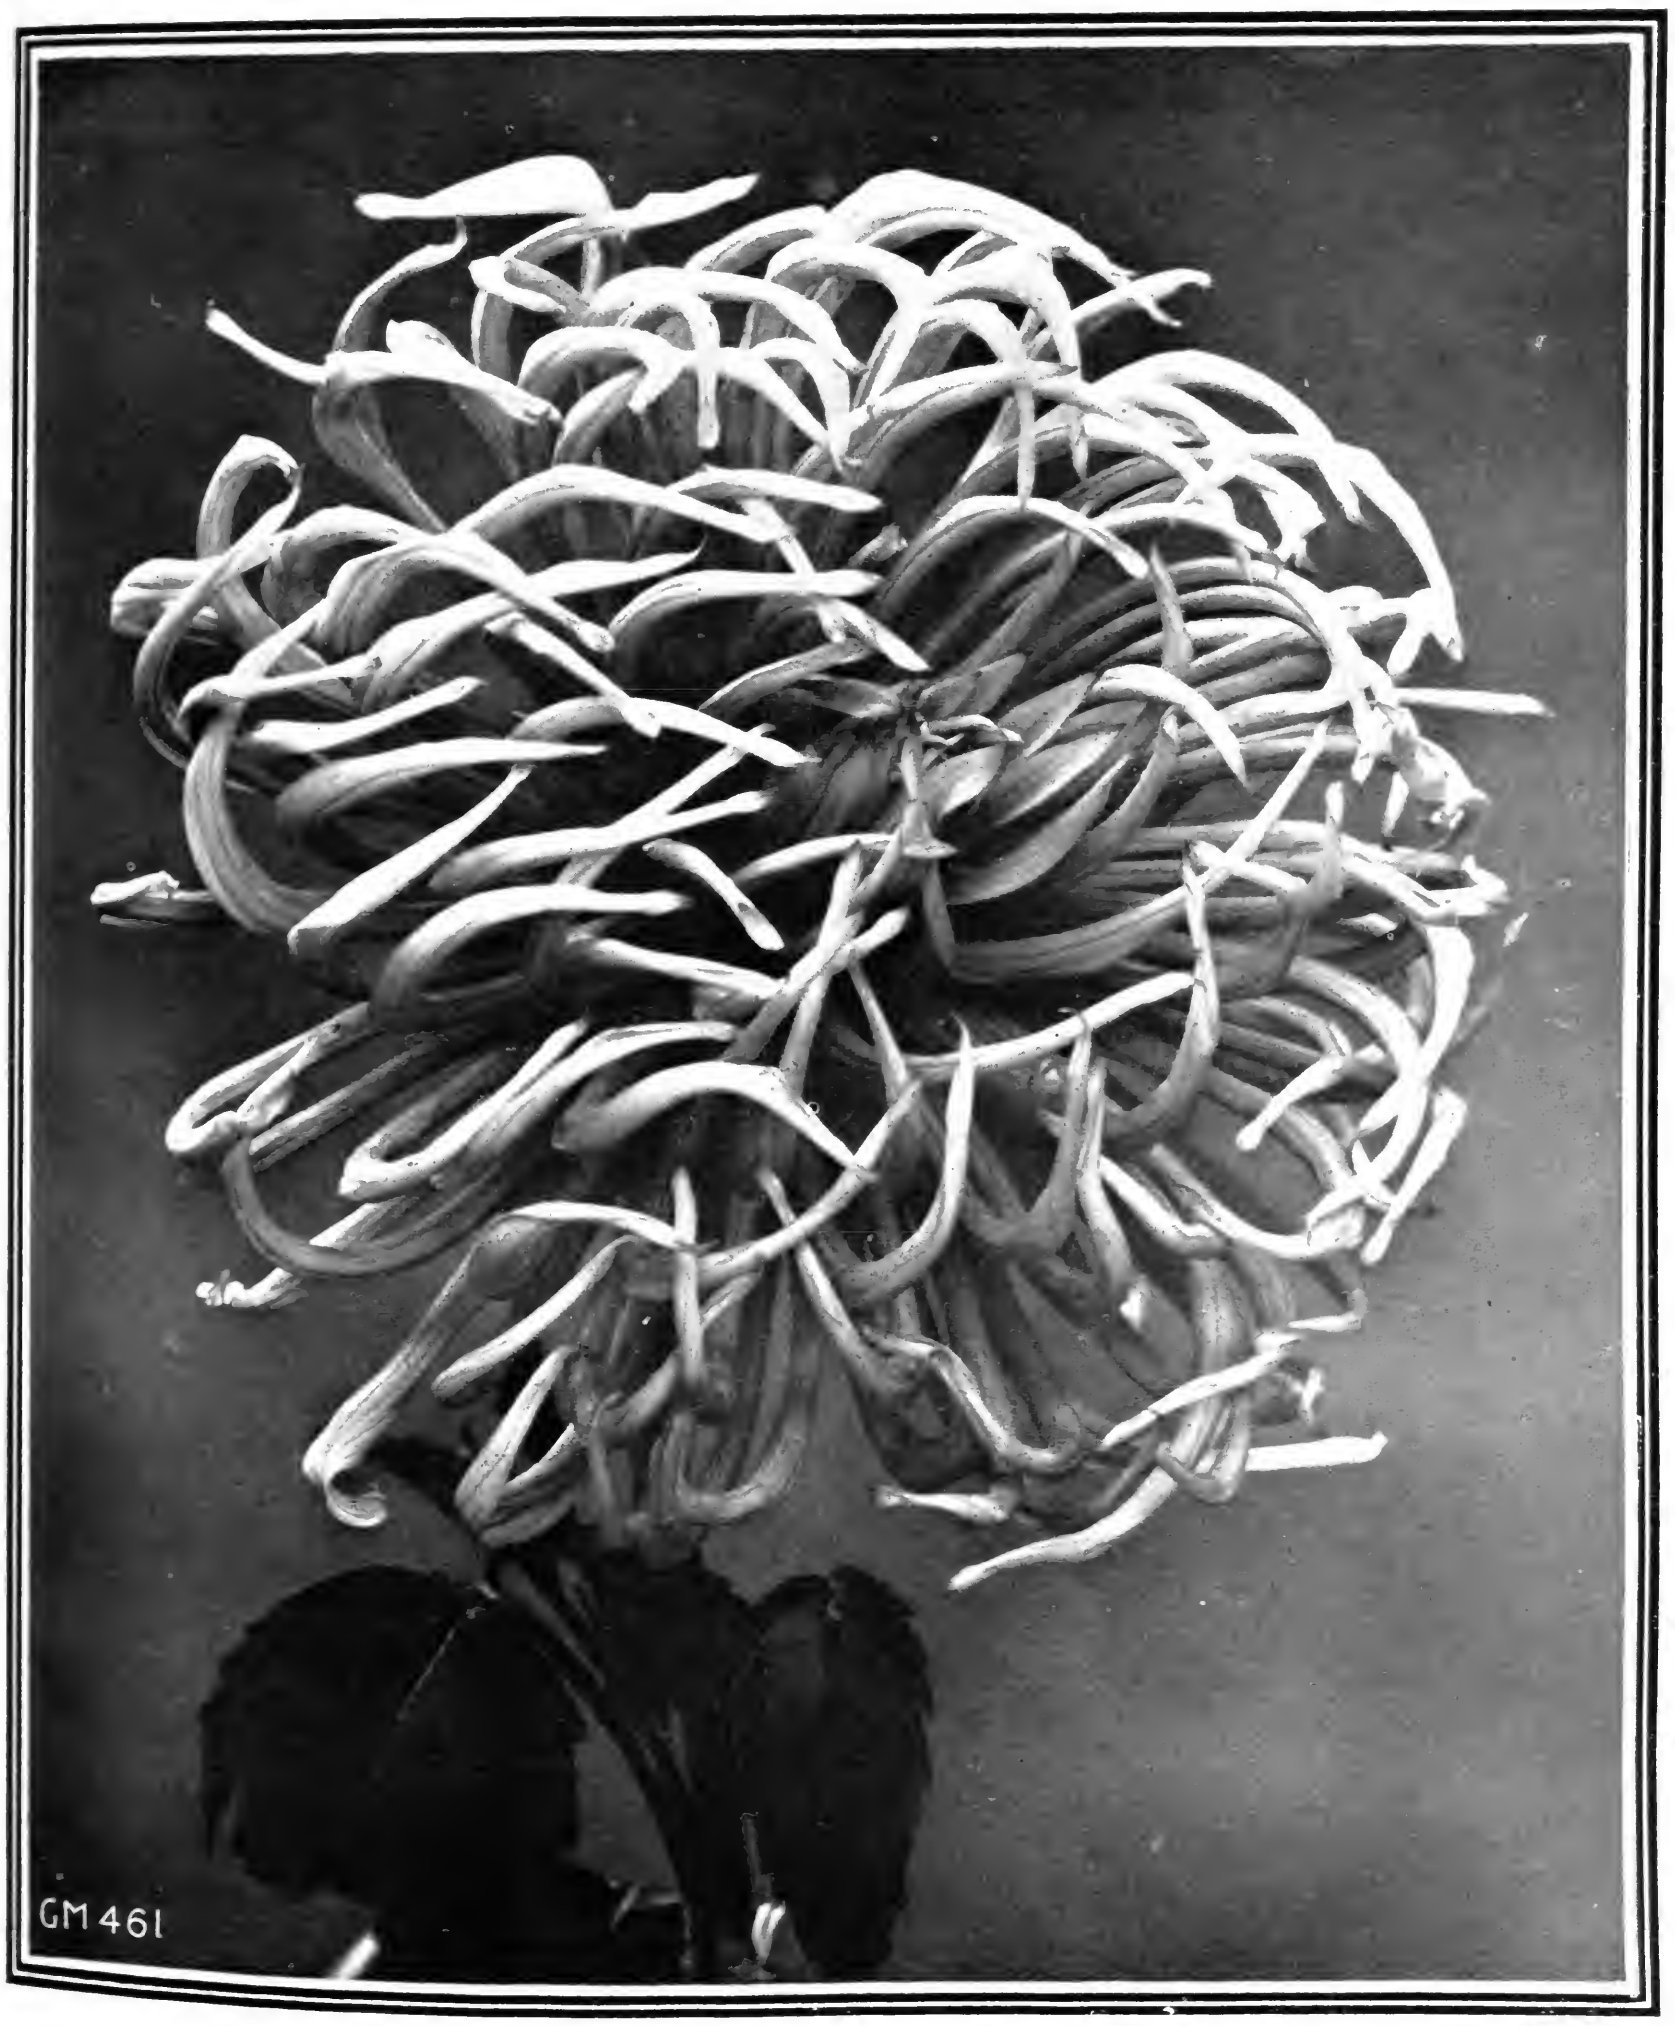
PAEONY FLOWERED DAHLIAS
IN PARKS AND GARDENS.

The rapid rise in popular favour of the paeony-flowered dahlias for garden decoration and cutting has been almost phenomenal. From a small beginning in 1905, when a few flowers were staged in London, these varieties have, in seven years, come to occupy a foremost position in our gardens. Should space in the garden or pleasure ground permit, it would be an easy matter to get together a collection of one hundred named sorts.

To a Dutch grower belongs the honour of the introduction of this race, but several British growers quickly recognised the possibilities of such flowers, and have easily out-distanced their Dutch neighbours in the raising of new and improved varieties. A glance at the names of the newer sorts is ample evidence of this, for whereas the first dozen we grew all had Dutch names, with few exceptions the newer introductions have British names.

Though first greeted with uncomplimentary remarks, the undoubted merits of the pæony-flowered dahlias for garden decoration attracted the attention of flower lovers, i.e., those who grow the flowers which make the greatest show in the garden without an exceptional amount of care and attention. One has only to visit a London flower show in the autumn to recognise the demand of the buying public for the pæony-flowered dahlias. With few exceptions, trade growers give this section the most prominent position in their groups, and they would not do this unless there was a demand for the plants.

The two most important considerations in dahlias for garden decoration are freedom of flowering, and that the blooms shall be borne on long, stiff stems well above the foliage. The pæony-flowered section fulfil both of these conditions, and are robust in habit. The earlier varieties were generally tall and vigorous in growth, and thus not altogether suitable for small gardens. British raisers speedily remedied this failing, and among the newer sorts a number are dwart in habit. A few of the best of these are included in the list of varieties at the end of these notes.



CACTUS DAHLIA GEORGE SCHOFIELD.
Flowers pink with yellow centre. Raised by Messrs. J. Stredwick and Son.

For public parks and gardens, where, as a rule, there is ample space for growing effective masses or groups of plants, the pæony-flowered dahlias are unsurpassed by any of the other eight or ten sections into which dahlias are divided. Another point in favour of the dahlia is their adaptability to the climatic conditions of a town garden, the dahlia always being looked upon as a valuable town plant, and, of necessity, the most frequented public parks and gardens are situated in or near large towns.

While, for the sake of variety and interest, it is desirable to grow a large collection of varieties in large parks, the most striking effects are obtained, particularly at a distance, by planting bold masses or large beds of one sort. For this purpose the creamy-yellow variety, King Leopold, holds a foremost place, and other effective sorts for grouping are Duke Henry, Liberty, Mrs. T. G. Baker, and Baron G. de Graucy, while the newer Countess Grey should prove effective when widely distributed. For a collection of named varieties a border should be set apart, not too wide, easy of access by visitors, and with each variety plainly labelled. While the interest of the public in gardening seems to be yearly on the increase, it is also the duty of the man in charge of a public garden to foster this regard and interest, not only for the honour of his own department, but also for the sake of the horticultural community at large. We find a named plant more attractive to visitors than unnamed ones, and the name is often jotted down in a note book.

In addition to the self colours, the blending of numerous soft and delicate tints or the shading of others is very pleasing in these dahlias. Ladies in particular are attracted by the wonderful tinting and shading, particularly when the flowers are cut with long stalks, and used in large vases for indoor decoration. The following list is sufficient evidence of the wide range of colour present in the pæony-flowered dahlia of to-day.

The varieties preceded by an asterisk indicates the twelve most suitable varieties when only a small number are required:

Baron G. de Graucy.—Creamy-white flowers, borne on long stems.

Bronze Gem.—Rich bronzy-red, very effective in large groups.

Careless.—A deep claret shade, or carmine-rose.

*Codsall Gem.—Deep yellow centre, lighter towards the edges of petals, dwarf in habit.

Colonel Cody.—Yellow, shaded with buff and apricot, dwarf.

*Connie Humphreys. — Light yellow centre, shading to white at the ends of the petals, dwarf habit.

*Countess Grey.—A delightful shell-pink shade, one of the best novelties of 1912, dwarf grower.

*Countess of Lonsdale.—A rich maroon-crimson, very distinct and effective flower.

Dr. K. W. Van Gorkom.—White, deeply shaded rose, one of the older varieties, and still a favourite.

*Duke Henry.—Dark red, with a shade of carmine.

Fanny.—Amber-yellow, suffused with pink.

Faust.—A brick-red shade, marked with orange.

Geisha.—Orange-scarlet and yellow.

Germania.—A crimson-scarlet variety, and one of the most popular of the older introductions.

Glory of Baarn.—Lovely soft pink, large blooms, borne on stiff stems.

*Hon. Mrs. Walter Forbes.—Orange-yellow.

*King Leopold.—Canary or creamy-yellow, the tallest variety we grow, grand for massing in large beds.

Lady Cleeve.—Yellow, suffused with mauve.

Lady Muriel Paget.—One of the best pure whites.

Lady Norman.—Apricot-yellow, suffused with pink.

Lady Saville. — Rich orange-scarlet, tipped with buff, an effective flower.

Leveller.—Rich crimson, good grower.

*Liberty.—Perhaps the brightest of all the red varieties, scarlet-red.

Merveille.—An effective orange-yellow shade.

*Mrs. A. McKellar.—Terra-cotta, shaded salmon, a charming shade.

Mrs. E. J. Wythes.—Carmine-rose, white centre.

Mrs. Geoffrey le M. Mander.—Bright rose, shaded yellow and white.

Mrs. George Gordon.—Creamy-white, a massive flower, and a very desirable variety.

Mrs. R. Cooke.—Rosy-carmine, with lighter shading at edges of petals.

Mrs. T. A. Weston.—Opening creamy-white, later shaded with pink, yellow centre; a novelty of 1912.

*Mrs. T. G. Baker.—One of the largest and best pure white varieties.

Mrs. W. E. Whineray.—Rosy-mauve, yellow centre, a large flower.

*Mrs. W. Kerr.—Pale pink, suffused rose, one of the best of the dwarfer varieties.

Romolo Piazzani. — Yellow ground, shaded with salmon.

Queen Emma.—Rosy-lilac, one of the first introduced, and still worthy of a place in large collections.

Salome.—Bright orange, shade buff.

Sunset.—A useful dwarf variety, orange-yellow and red.

S. T. Wright.—Reddish-apricot, yellow centre, very free.

The Warrior.—Deep red, shaded plum, habit dwarf.

*W. H. Morter.—Golden-yellow and red, distinct, dwarf, and beautiful.

A. Osborn.

GARDEN CACTUS DAHLIAS.

To meet the demand caused by the development of a taste for cactus dahlias, suitable for garden decoration, specialists are now concentrating much time and attention on the raising of varieties specially adapted for that purpose.

Tastes and fashions change. It was not so many years ago that it was almost useless, from a trade point of view, to place any new cactus dahlia on the market that did not come up to the exhibition standard when cut and arranged on a show-board. Discussing this subject recently with a member of an old firm closely associated with the dahlia, he gave it as his opinion that many beautiful flowers, which would have proved great acquisitions for the garden, had been thrown on the rubbish heap. It was so in the case of his firm. We may therefore reasonably hope that, as raisers have now encouragement to introduce cactus varieties specially suited for the garden, we shall see in a few years striking improvements on existing varieties. As lovers of the garden cactus, however, we have reason to be satisfied with the advance made during the last two years. Such sterling varieties as Record, Sunray, Richard Box, Stability, Jenny Wren, Kathleen, Bridal Crown, and Treasure, to mention only a few, have been sent out. Many others have received high commendation from the N.D.S. and other societies, and we hope the trials this year will reveal a number of others that are really good. In any case, it should sift the wheat from the chaff.

It is hardly necessary to say that an ideal plant should have its flowers thrown well above the foliage on erect stalks. There are scores with hard, wiry stems, but perfection has not been reached. In many cases they have the fault of the stalks not being quite long enough. There are, however, many with flowers that rise sufficiently above the foliage to make a dazzling display in the autumn.

Varieties.

The following twelve are really good, give a wide range of colour, and in most cases the flowers are produced in profusion well above the foliage. Miss Willmott, orange-yellow, 5ft.; Penguin, pale gold, 4 to 5ft.; Sweet Briar, beautiful pink, 3ft.; White Ensign, 3ft.; Hon. Mrs. Greville, orange, tinted pink, 4ft.; Erecta, pretty shade of pink, 3½ft.; Manve Queen, 3ft.; Mary Purrier, scarlet, 4ft.; Rosetta, violet rose, 3½ft.; Star Gazer, yellow, shading to rich apricot, 3ft.; Mrs. J. H. Usmar, coppery-orange, suffused coral pink, 4ft.; Stalwart, crimson-scarlet.

Yellow, in varying shades, with suffusings and tippings of other colours, predominate in the best garden cactus dahlias, and, consequently, many that are good are omitted from this list.

Miniature or Pompon Cactus.

The miniature or pompon cactus dahlias are of somewhat recent introduction, and when carefully selected charming subjects for the garden. They are the exact counterpart of the others, except in size of bloom and plant. For planting along the front of borders or on the margin of beds in which the larger kinds are planted, they are very useful. They are also most attractive in beds wholly devoted to them. These also are receiving attention at the hands of the raisers, and several varieties have favourably caught the eye of the National Dahlia Society and the Royal Horticultural Society's Committees. The variety Kathleen, herewith illustrated, has all the qualifications required of a garden plant, combined with freedom of flowering, with blooms borne on long, wiry stems, and is bound to become very popular. The colour, lilac-mauve, is somewhat of a rarity in this class. A few of the best of the generally known varieties are Queen of Pinks, pink; Coronation, bright crimson-scarlet; Mary, centre of petals pure white, edged crimson; The Bride, pure white; Mignon, bright pink, base of petals lemon; Sovereign, yellow, and Cerise Gem. The varieties contained in these two lists cannot fail to give satisfaction if assisted with proper cultivation.

Culture.

It is to be feared that the garden cactus dahlias are not always given a proper chance of showing their true value. Tiny young plants are in many cases put out, and have for some time to fight for their very existence, unless the weather should be particularly kind and assist them with warm rain, and dull days. First, then, the foundation of the dazzling displays to which we all look forward, can only be laid by putting out strong, healthy plants. This is even more important with the cactus section than some other types, for many of the earliest blooms, on the very best varieties, are partly hidden while the plant is making strong growth. It is therefore necessary to have a good start, and build up a fine plant ready to flower at

the beginning of August. It will then have its energies concentrated on fulfilling its mission, namely, producing flowers in abundance, instead of foliage, which would be the case with those which are late. To procure fine plants they should have their final potting about the end of April, or in the first week in May, and be then put into the largest pots they are likely to profitably fill with roots by planting-out time.

When potted, place them in a frame, and keep close for a few days, shade from very strong sun, and spray occasionally with rain-water. After a few days commence to give air; gradually increase it as the growth progresses; spray the plants, and close the frame early for a time. Under such treatment healthy plants will quickly establish themselves in their new pots, and, though they may not appear to be growing freely, they will be rapidly making roots, which is of vital importance. Give air freely according to the weather, eventually allowing full exposure, and aim at sturdiness. If the plants have come through to this stage free from insect pests, there will not be much to fear under good culture.

Preparation of Soil.

During the winter the ground intended for them should have received attention in the way of trenching or deep digging, and the surface left in a rough state. Here a few words as to manuring may be useful. This is a point on which various opinions exist. In my opinion heavily-manured ground is not advisable for garden dahlias, for it has a tendency to encourage an excessively luxuriant growth and a correspondingly small percentage of blooms. No hard-and-fast rule can be laid down. A poor, impoverished soil will certainly require manure in moderation. For a well-drained heavy soil, such as the plants thrive in, the best method is to scatter a small portion of very short rotten manure (we use mushroom manure) over the entire surface, at the end of April, and fork well in. The top may still be left rather rough, and finally broken down with rakes a week or two before planting time.

Planting.

This important operation should commence in the last week of May or in the first week of June, according to climatic conditions, and Cowper's words—

"The crowded roots demand enlargement now,
And transplantation in an ampler space.
Indulged in what they wish, they soon supply
Large foliage,"

seem particularly appropriate. If time permits—and it will be time well spent—it is an excellent plan to have a well-prepared mixture of soil ready to place around the roots of each one. It is remarkable what a help this is to them. Failing that, work the finest soil obtainable near the roots. Carefully stake each plant as the operation proceeds, and pay attention to tying as required. If the position is an open one, not sheltered from winds, it will save much anxiety when rough weather prevails. Sufficient space must be allowed for full development. Four feet may be taken as a good average for the larger type, and three and a-half feet for the pompon cactus. A little soot and lime scattered around the stems will assist in keeping away slugs, and be beneficial to the plants.

If plants from cuttings are used no thinning will be necessary, unless they are backward, in which case it would be well to assist them by allowing fewer growths. In the case of old tubers, three shoots may be taken up, each one, of course, receiving a stake, and no thinning ought to be required. Water two or three times a week until well established, unless one is fortunate enough to be saved this trouble by Nature's watering-pot.

Duffryn Gardens. ARTHUR J. COBB.

AMONG THE ALPINE FLOWERS.

"Is this a time to be cloudy and sad,
When our mother Nature laughs around;
When even the deep blue heavens look glad,
And gladness breathes from the blossoming ground?" *W. C. Bryant.*

Truly is the spring a time of rejoicing to the lover of the alpine flowers. From rocks and banks these favourites spring; from the margin of the water garden, or from the bog they send up their beautiful blossoms to gladden his admiring eyes. We may not yet be in the full enjoyment of the utmost wealth of our rich array of early alpines, but we have passed the threshold, and are delighting ourselves with the charms of the beauties which present themselves for us to admire. To choose from among the many, without appearing to pass a slight upon those we cannot praise, is to run a serious risk lest we should be misunderstood, and lest it should be supposed that only the flowers we name are worthy of notice. That is a grave error, yet we must run the risk and select a few only from the wealth of grace and beauty which is spread before our choice.

Saxifraga Petraschi.

Many saxifrages are before us, and it is impossible to select one or two without feeling that, after all, we are neglecting the opportunity of doing justice to other and equally lovely flowers. Yet as we look upon Saxifraga Petraschi, we feel that this is one of the saxifrages which call for notice now, though it will shortly be past in the south, if not already gone. It is one of the many white-flowered rockfoils which present themselves in a perfectly embarrassing array for our suffrages.

It is presumably a hybrid, and, in all probability, S. Burseriana is one of its parents. Its pleasing spiny foliage is attractive enough, but it is when it is in bloom, with its sheets of biggish flowers (one speaks comparatively, using S. Burseriana as one of the comparisons), it is handsome, with its lovely white flowers borne in closer array than on many others of this Kabschia section. On a rocky knoll it looks charming, with the pure white flowers thrust up from between the rocks or spreading into little masses, and contrasting well with the dark stones. S. Petraschi seems to be easier to do than many of its kindred of the Kabschia group, and a little top-dressing annually, or twice yearly, will do much to prolong its health and happiness, and will conduce to the greater enjoyment of its owner. Where S. Petraschi came from I cannot tell, but it does no discredit to its place of origin.

Epigæa repens.

The charming Mayflower of North America, or the ground laurel, as it is also named in its native homes, is a beautiful shrub for the shadier and cooler parts of the rock garden, and in a cool corner its leathery leaves, brightened by the racemes of little pink and white flowers, are extremely beautiful in their own modest way. There is here no garish attempt to reveal any points of gay colouring. The reverse is the case. Epigæa repens compels admiration by its modest mien, and by its simple beauty. One cannot help bestowing one's admiration upon it, as we see the contrast between the leathery, shining leaves and the wax-like, delicately-coloured blossoms. This mayflower is a plant for the cool and shaded part, and in a nook of the rock garden well towards the base and facing north it will be at home, and will creep along and soon occupy a good space. It loves peat, but will not despise loam. It likes moisture at the roots, yet will not rebel against a drier place among stones. At home it revels in sandy soil, or in rocky ground, but there it must have the shade of trees to give it fullest success. This is a sufficient hint to all who attempt this charming little shrub, and who seek to accommodate it as happily as may be in its land of adoption.

Primula Forresti.

One finds a curious difference of opinion about Primula Forresti, yet those who have studied the genus well, and who see this plant in proper condition, and in fitting surroundings, cannot but praise the beautiful, yellow, drooping flowers. They are of a bright yellow, and pass off to orange. The leaves have long petioles, and they, and the flowers, have the fragrance of ripe fruit. It may appear superfluous to describe a primula such as this, which has for some time been before the public, but one always finds many readers who have not become acquainted with such a flower, or who have been deterred by its previous cost from acquiring it.

P. Forresti is now cheap, and it may well find its way into many more gardens. Raised from seeds, it can be obtained in quantity, but it is so free that it divides well after a year or two. I am of opinion that it likes a moist soil, and that it will flourish under the same conditions as Primula Bulleyana. I have generally met with it about six or nine inches high, so that it may be welcomed as a good addition to even the small rock garden.

Other Flowers.

There is a perfect galaxy of other flowers. Anemones of the nemorosa, pulsatilla, vernalis, and other types; violas in plenty; rock or bog-loving primulas in alluring choice; the later daffodils and narcissi; the dwarfer tulips; quaint and curious fritillarias; still some late grape hyacinths, crocuses, arabises, American erythroniums of exquisite beauty, aubrietias, potentillas, and dwarf alliums, with a cytisus or two. The Canadian bloodroot, and many other flowers, are in blow, attesting the kindliness of the flowers in ministering to our delight.

S. ARNOTT.

AMASONIA CALYCINA.

This is a very showy winter-flowering plant of neat habit of growth. It should be propagated in spring from the side shoots and grown in gentle heat throughout the summer. The cuttings should be taken off when they are about three inches long, and inserted in small pots filled with peat and sand. If stood in a propagating case they will soon root, and then should receive a shift into pots of larger size, this time adding a little loam to the compost.

By autumn the plants will be about a foot high, and will then commence to bloom. When in flower they are very interesting objects, as the bracts, which are red, are produced freely on the upright spikes. The calyx of the flowers is also red, while the corolla is of a sulphur-yellow colour, which makes the plants very attractive.

H. C. P.

SWEET PEA NOTES.

Even in wet, cold districts the planting season is now in full swing, and where advantage was not taken of the few dry days earlier in the month, no opportunity should

POMPON CACTUS DAHLIA KATHLEEN.
A new garden variety with rose-mauve flowers. Raised by Mr. J. T. West.

now be lost of putting the plants out, for should the weather turn warm early in May they will commence blooming before they have made sufficient new roots to sustain them properly, and so may keep in a rather weakly condition throughout the whole season.

I have often put forward the advantage to be gained from shaking the roots almost free from soil before planting, and at no time is this more necessary or essential than late in the season; when the roots are left in a mass the heat of the sun quickly dries this out, and the plant suffers considerably even though the soil may be comparatively moist all round them. The removal of soil is not the check some people would have you believe, provided due and proper care is taken to fill fine soil firmly around the well-spread-out roots. This and a few sprayings overhead on warm dry days will soon set the plants growing again, and, though they may not at first appear to grow so quickly as those not shaken out, at the end of a month or even less they will be in a much better condition to stand the effects of drought.

Planted out sweet peas do not suffer so much from the ravages of slugs as do those sown in the open ground, but these pests are sufficiently dangerous, especially during a wet spell, to make a note of warning not out of place; do not forget a light dusting of soot every week or ten days. If this is not absolutely necessary as an antidote to slugs, it adds just a little fertiliser to the soil, which is a decided advantage.

Early-planted Sweet Peas.

Those who were fortunate enough to plant out during the mild, dry spell early in March have every reason to congratulate themselves, and the condition of the plants now (although we have had 10 degrees of frost on them) fully bears out my advice to plant as early as possible in March, providing the soil and weather conditions are favourable. Rarely have I seen peas looking so well as those on moderately light soil, planted some five weeks ago; unfortunately, our soil was too wet to plant upon until about April 7, and then the holes had to be filled in with prepared soil.

During the winter one has seen the use of potash manures almost universally advocated, and in some instances even to the exclusion of other forms of manure equally as essential. Those of us who have watched the effects of various manures on sweet pea plants over a lengthened period, know to what extent potash may be used to advantage. By these remarks I am not under-estimating the great value of potash, but those growers who desire a vigorous growth in their plants, over a long season, will be well advised to proceed with caution, as an over-supply of this fertiliser will harden the bine much more than is desirable. Although potash may be one of the best manures to use for warding off an attack of the dreaded streak disease, I am quite convinced that a fairly vigorous and free growth is also one of the points that should be aimed at. Permanganate of potash, just sufficient to colour the water, may be used as a spray for the foliage, and this might prove as effective as a great deal of potash applied to the roots.

Thomas Stevenson.

Woburn Place Gardens.

CLERODENDRON FALLAX.

Though this plant has been known in gardens for a great number of years, it is not often that we see it well grown. Why this should be so is difficult to understand, seeing that its cultivation is of the simplest form possible.

Plants may be raised from cuttings inserted in a brisk heat in spring, or from seeds sown as soon as ripe. Those from cuttings make the most compact specimens, while seedlings usually make but one shoot and flower from the crown, forming quite a large head of bright red flowers, which last a long time in perfection. As a decorative pot plant this is very showy during the winter months on account of its colour.

When the plants have received their final shift in June they should be transferred to a cold frame, but the lights must be kept close and the plants shaded from the sun until well established, a little air being then admitted on all favourable occasions when the weather is warm. One of the great mistakes made in growing these plants is keeping them too warm in the summer, as growth so made is flabby, and therefore the plants do not bloom so freely as they otherwise would.

H. C. P.

NEW PLANTS AND FLOWERS.

BRASSO-LÆLIO-CATTLEYA KING EMPEROR.

A very fine trigeneric hybrid, the parents being Lælio-cattleya callistoglossa and Brasso-cattleya Digbyano-Mossiæ. The flowers are eight or nine inches across, white, tinted with lilac, the big wide lip deep purple with a paler margin, and a yellow and white throat. F.C.C., R.H.S., April 15. W. R. Lee, Esq. (gardener, Mr. Branch), Plumpton Hall, Heyrod, Manchester.

LÆLIO-CATTLEYA LUMINOSA HOLFORD'S VARIETY.

This is a glorious orchid with large flowers, the outspread sepals and petals being rich, almost golden, yellow, while the bold lip is intense crimson-purple with deeper shading. F.C.C., R.H.S., April 15. Lieut.-Colonel Sir George Holford.

MAXILLARIA FLETCHERIANA.

A curious and distinct species imported from Peru. The fleshy flower is carried on an erect, stout scape, and has creamy-white sepals and petals, these having rose-red lines, but the lines are heaviest upon the petals. The tip is tawny yellow. A.M., R.H.S., April 15. Messrs. Sander and Sons, St. Albans.

ODONTOGLOSSUM MRS. THOMPSON.

Of unknown parentage, this attractive hybrid has white-ground flowers, heavily blotched with deep violet-purple. The white apex to the lip is very clear. A.M., R.H.S., April 15. W. Thompson, Esq., Walton Grange, Stone, Staffs.

ODONTOGLOSSUM PESCATOREI LADY HOLFORD.

A lovely form, with exceptionally large flowers, fully 3½ inches across. The petals are white, and have in almost every case one purple spot; the sepals are white, faintly rose-tinted towards the apex. Lip white, with red-purple marks in front of the yellow crest. F.C.C., R.H.S., April 15. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

ANDROSACE TIBETICUM.

A dainty little plant, collected by Mr. Purdom in Northern China. It grows about two or three inches high, and has little tufts of neat, hairy green leaves. The flowers are in little umbels of eight or twelve tiny, blush pink flowers. Each bloom has a tiny yellow eye. Altogether a charming little plant that should become very popular with lovers of alpines. A.M., R.H.S., April 15. Messrs. Jas. Veitch and Sons, Chelsea.

AURICULA SUFFRAGETTE.

An attractive fancy variety, with large yellow flowers, each having a well-defined white band of paste. A.M., R.H.S., April 15. Mr. Jas. Douglas, Great Bookham.

DAFFODILS.

Mrs. Ernst Krelage.—A very lovely white trumpet daffodil with a faint creamy tint in the finely-formed and beautifully-frilled trumpet. The latter is 1½in. long, and as much broad across the mouth. The perianth has a spread of four inches, the outer segments being 1⅝ inch broad. This variety gained an Award of Merit in 1912, and now receives the higher award. F.C.C., R.H.S., April 15. Messrs. E. H. Krelage and Son, Haarlem, Holland.

Cædmon.—A fine poeticus variety of strong growth, fine form, and substance. The crown is broad, orange in the centre, with a zone of yellow, and a broad rim of dark cinnabar red. The outer segments were 1⅝ inch across, and the whole flower 3½ inches wide, while the crown is ¾ inch broad. A.M., R.H.S., April 15. Messrs. Barr and Sons, Covent Garden.

St. Olaf.—A charming Leedsi variety with broad soft white perianth segments, the outer ones 1⅝in. across; the frilled crown is 1½in. wide, and the whole flower is 3½ inches across. This has stout but not massive stems. The crown is greenish yellow right in the centre, but otherwise the colour is deep cream, with a very pale yellow rim. A.M., R.H.S., April 15. Messrs. Barr and Sons, Covent Garden.

Europa. — A grand upstanding trumpet variety, stout-stemmed, finely-formed, substantial, and handsome. The broad perianth segments are white, the bold trumpet being pale-yellow with a deeper tinge in the frilled rim. A.M., R.H.S., April 15. Messrs. Barr and Sons, Covent Garden.

HIPPEASTRUM EURASIAN.

A large and beautiful variety with very broad, rounded segments. The colour is deep and rich rose-red or carmine-rose, a distinct and lovely shade. A.M., R.H.S., April 15. Messrs. Jas. Veitch and Sons, Chelsea.

PRIMULA MAXIMOWICZI.

A distinct and faintly fragrant species, collected by Mr. Purdom in Northern China. The leaves are lanceolate, rather fleshy, and slightly waved along the crenate margins. From the centre of the tuft of foliage rises a stout spike, about nine inches high, bearing a dozen or so of small, pendulous flowers upon its upper four inches. These flowers are deep cinnabar-crimson, and produced in distinct tiers, but more often the fashion of P. japonica than P. sinensis, for the axis does not appear to elongate in P. Maximowiczi. A.M., R.H.S., April 15. Messrs. J. Veitch and Sons.

NARCISSUS CÆDMON.

A beautiful Poeticus variety, finely proportioned, with substantial, rounded, pure white segments and a yellow crown that is red at the base, and has a well-defined cinnabar-red rim. A.M., R.H.S., April 15. Messrs. Barr and Sons, Covent Garden.

HELICHRYSUM BELLIDIOIDES.

A lowly, hardy, perennial "Everlasting" flower, figured on p. 286, in our issue of April 19. This species seems especially made for the rock garden, and for a warm, rather dry place; it has creeping stems and tiny, ovate, greyish leaves that are silvery on the under side. The flowers are about half an inch across, borne singly on 3in. to 4in. stems, and they are white with yellow centre, the ray flowers being sharply-pointed. A.M., R.H.S., April 15. Mr. A. Hemsley, Crawley.

PRIMULA VISCOSA BEAUTY.

A beautiful garden primula derived from P. viscosa (hirsuta) crossed with Auricula Innocence. The trusses are large, and the individual blooms about 1¼in. across, bright violet-purple with a white eye. A.M., R.H.S., April 15. Mr. James Douglas, Great Bookham.

MAIN CROP AND LATE PEAS.

The task of keeping up a constant supply of green peas of good quality throughout the season taxes the skill of the cultivator under any circumstances, and there is increased cause for anxiety if the weather during summer proves to be very dry. It is at this season that the greatest difficulties commonly arise, in connection with our endeavours to avoid a break in the supply, and unless they have been carefully guarded against, by skilful management, in the preparation of the soil, and other important details of culture, we cannot reasonably expect to be wholly successful.

Very early crops produced from sowings made under glass are naturally much valued, and cultivators sometimes receive deserved praise and commendation for the pains taken and skill displayed in their production, but I suggest that, as a rule, they are comparatively easily obtained as compared with good mid-season and late crops.

All experienced cultivators will agree that soils vary considerably with reference to their suitability for culinary peas, but whatever their character, whether heavy or light, deep cultivation and liberal supplies of manure (farmyard by preference) are important factors in contributing to success. My experience with heavy land leads me to prefer the work being done in autumn or early winter, for if left until after these dates, the soil becomes too wet to be satisfactorily trenched until spring, and when done at that time the soil does not sufficiently consolidate to prevent the crops suffering in a greater or lesser degree from the effects of excessive aridity.

To clear land of slugs it should be dressed with gas lime some weeks previous to being cropped, at the rate of a wheelbarrow load to a perch, and in any case when being prepared for plants or seeds have its surface deeply broken and raked over. In cases where the soil is deficient of lime, a fair dressing, if applied in spring and forked in, will be beneficial to the crop. An important matter that has of late years been often advocated by some of our most successful practitioners, and is, consequently, becoming more general than formerly, is that of sowing or planting very thinly, and allowing increased space between the rows of the plants, the distance in either case being governed by the height and strength of the variety grown.

On dry land, especially, it is advisable to sow in trenches, and this practice answers best when it is done upon previously trenched and heavily manured quarters. In cases, however, where the soil has not been treated in this way, the trenches should be deeply worked and have liberal supplies of rich farmyard manure incorporated with the soil.

Where heavy cold land, such as ours, has to be dealt with, better results can be obtained from crops that are sown previous to the beginning of April by raising plants under glass than can be done by sowing seeds in the open. In raising plants under glass the seeds can be sown in the old, well-known method, upon turves or in pots or boxes, and in either case be placed in a freely ventilated structure, be thoroughly hardened, and transplanted while they are still sturdy, and have their roots under close control. When planting those raised upon turves, the turves should be embedded, end to end, in trenches. Those raised in pots, after being turned out, should be planted in like manner. Plants raised in boxes must be carefully dealt with, be lifted without damage, and planted singly in rows or trenches, with two lines of plants forming each row. If the soil is in an unsatisfactory working state, some specially-prepared material should be firmly placed about the roots, and if the ground is very dry a good watering should be given once the planting is completed.

Successional late crops should be sown up to the first week in July, but as varieties vary considerably in the length of time they take in becoming fit for use, and as, moreover, the state of the weather has considerable influence upon this matter, no strict rule can be satisfactorily laid down respecting the time that should be allowed to elapse between each sowing. As a deterrent to slugs and birds, and also as a nourishing element, it is advisable to dress the plants while they are young with soot. A more efficient plan, however, of dealing with birds, is to protect with nets up to the time the plants are earthed and staked. As soon as the staking is done a good mulching with stable litter should be afforded to check evaporation, but in wet seasons, owing to the cold nature of our soil, we have found mulching more or less detrimental. At no time should the crops be permitted to suffer from lack of root moisture, and therefore thorough waterings with clear water, supplemented by occasional soakings of farmyard liquid manure, should be given whenever necessary. Upon dry soils especially a light dressing of nitrate of soda, distributed during the early stages of growth and immediately previous to rain or before watering, will invigorate the plants.

Mildew is one of the most virulent enemies that the cultivator of late crops of peas has to contend with. It is aggravated by negligent and unskilful culture, such as bad tillage, thick sowing, and shortage of root moisture, while some varieties appear to be more subject to its ravages than others. It is likewise more troublesome in some situations than in others; for example, high temperatures by day and low by night are favourable to its development and crops placed in low situations are very subject to its attacks.

Varieties have become so numerous as to cause perplexity; at the same time the raisers of new ones well deserve gratitude for the benefits that we receive from their hands, though I frankly admit that the number of varieties we grow here are somewhat strictly limited, and I am almost ashamed to admit that we are so far from being up to date in this respect as to have not yet had cultural experience with that remarkably fine main crop variety, Quite Content. Of main crop varieties, Alderman, Criterion, Duke of Albany, Prestige, and Veitch's Main Crop; and of late varieties, Autocrat, Late Queen, Sturdy, and Gladstone have invariably given us much satisfaction. Autocrat took the place of Ne Plus Ultra; it is excellent in every way.

The Hendre Gardens. T. Coomber.

PRIMULAS FROM A GARDEN POINT OF VIEW.

The following is the paper read before the Royal Horticultural Society at the Primula Conference, on April 16, by Miss Gertrude Jekyll, V.M.H.:

When we consider the main uses of our garden primroses we find that they fall into three groups, namely, those for borders, those for the rock garden, and those for boggy ground. The border kinds alone need a further sub-division, suggesting distinct ways of use, for there are what we call the true primroses, namely, those that are all on single stalks; there are the polyanthus or bunch primroses; then the old florists' polyanthus, the double primroses, and the border auriculas. They all agree in preferring the soil of light loamy character with some leaf-mould, and a place where they are never dried up, and where they can have either slight shade, or, at least, a non-sunny exposure.

Primroses.

The native primrose of our woods, one of the most charming of flowers, is no doubt the origin of the coloured primroses. If one might have a perfect place for them it would be a partial clearing in just such a region as the natural haunts of the wild plant—a wood of oaks with an undergrowth of hazel, such as occurs in nearly every farm and private property throughout the land, and not infrequently adjoins the garden. A path slightly depressed, with irregular, shallow banks on either side, and passing through the wood in easy sweeping lines, would provide the best possible way of growing and enjoying the primroses; for, though they are also indispensable in the actual garden, they are rather more rightly placed in the setting of woodland.

It will be all the better if the plants of the main sub-divisions are kept quite distinct, either by following one another along the length of the path, or by having a separate little path for each kind. This is the more desirable, because the varieties are so easily mixed by chance pollination by bees. Indeed, where the Giant cowslips are grown their influence is so strong that they must be kept quite away from the bunch primroses, and can hardly be admitted in the same garden.

The earliest to bloom will be the true primroses. Even these, if the best effect is desired, must have some kind of division in colour-grouping; for they vary from palest pink to richest crimson, and from faintest lilac to deepest purple, thus at once suggesting two distinct colour-groups. And there will be found a third group of warm colouring, of which the strongest are of a red approaching scarlet, which will agree with neither of the others, and must be treated by itself. It was from a purple primrose with a colour inclining to violet that Mr. G. F. Wilson raised his blue varieties. These again must be kept distinct from the rest, but they group charmingly with the very useful early-blooming white, seed of which can be found in the trade lists.

In these days when good hardy flowers are so much prized and so well used, it is difficult to account for the general neglect of the fine old double primroses. They should be in every garden, except those on light soils, for in these they do not flourish. In any soil of a loamy nature the double lilac, white, and pale yellow will grow freely, and are among the best of spring flowers. The crimson and some other shades are a little more exacting, but are well worth trying. The equal neglect of the old florists' polyanthus is more easy to understand, for, though it has much charm, it is rather a thing to look at in the hand than of value as a conspicuous plant for the garden; still, without considering the show points of special marking and lacing of edges, a free-growing strain of these might well be among our early flowers, and, planted rather closely and fully set with bloom, would have an effect of richness that would be of

ENCYCLOPÆDIA OF GARDENING.

tion, front of shrubberies. Plant, Nov. to Feb. Propagate by seeds sown ¼ in. deep outdoors in March, or in boxes of light soil in temp. 55° in Feb.; cuttings inserted in sandy soil under bell-glass in Oct.; layering in Oct. C. alnifolia suitable for forcing to flower in winter.

SPECIES CULTIVATED: C. alnifolia (Sweet Pepper Bush), white, Sept., 4 ft., Florida; alnifolia Michauxii, 4 ft.; alnifolia paniculata, 4 ft.; acuminata (White Alder), white, Sept., 10 ft.; arborea, white, Sept., 8 ft., Madeira; canescens, white, Aug., 8 ft., China.

Clianthus (Glory Pea; Parrot's-bill; Sturt's Desert Pea).—Ord. Leguminosæ. Greenhouse climbing shrubs & herbaceous perennials. First introduced 1832.

CULTURE: Compost, two parts loam, one part leaf-mould & silver sand. Position, pots or beds in greenhouse. Pot or plant, March. Prune in April, shortening young shoots to within 2 in. of their base. Water freely March to Sept., moderately afterwards. Syringe foliage daily April to Aug. Temp., Oct. to March 45° to 50°; March to Oct. 55° to 65°. C. puniceus succeeds outdoors against warm walls in Devonshire. Propagate by seeds sown ¼ in. deep in well-drained pot of light soil in temp. 75° in March; cuttings of shoots inserted in sandy soil in temp. 75° to 85° in March or April.

SPECIES CULTIVATED: C. Dampieri, scarlet, April, 3 ft., Australia; puniceus magnificus, crimson, May, 6 ft., New Zealand.

Cliff Brake Fern.—See Pellæa.

Climbing Dahlia (Hidalgoa Wercklei).—See Hidalgoa.

Climbing Fern (Lygodium scandens).—See Lygodium.

Climbing Fumitory (Adlumia cirrhosa).—See Adlumia.

Climbing Groundsel (Senecio mikanoides).—See Senecio.

Climbing Hydrangea (Schizophragma hydrangeoides).—See Schizophragma.

Climbing Snake's-tongue Fern (Lygodium scandens).—See Lygodium.

Clintonia.—Ord. Liliaceæ. Hardy herbaceous perennials. First introduced 1788.

CULTURE: Soil, sandy peat. Position, moist shady border. Plant, Oct. or March. Propagate by division of roots in March or April.

SPECIES CULTIVATED: C. andrewsiana, rose, April, 2 ft., California; borealis, yellow, May, 1 ft., N. America; umbellata (Syn. Smilacina umbellata), white, May, 9 in., N. America; uniflora (Syn. Smilacina uniflora), white, July, 6 in., California.

Clitoria (Butterfly Pea). — Ord. Leguminosæ. Stove evergreen flowering climbers. First introduced 1739.

CULTURE: Compost, equal parts peat, leaf-mould, loam, & silver sand. Position, pots, tubs, or beds in light plant stove. Pot or plant, March. Water freely April to Sept., moderately afterwards. Temp., Oct. to March 55° to 65°; March to Oct. 70° to 80°. Propagate by seeds sown ¼ in. deep in light soil in temp. 75° in March; cuttings of side shoots inserted in sandy peat in temp. 80° at any time.

SPECIES CULTIVATED: C. ternatea, blue, July, 4 ft., E. Indies; ternatea alba, white, May; ternatea cærulea, blue, May; ternatea major, brown, Aug.

Clivia (Caffre Lily).—Ord. Amaryllidaceæ. Greenhouse evergreen flowering plants. Fleshy-rooted. Formerly known by the generic name of Imantophyllum. First introduced 1823.

CULTURE: Compost, two-thirds good loam, one-third decayed manure & sand. Position, sunny, close to glass in greenhouse. Pot, Feb. Water freely March to Sept. 65° to 75°. Propagate by seeds sown in light soil in temp. 75° in March; division of roots at potting time.

marked value among the flowers of the spring season.

Bunch Primroses.

Following the true primrose in time of blooming are the large bunch primroses, and of these, though there are also fine things among the pink and red colourings, the best in garden effect are the whites and yellows. Carefully grown strains, the result of nearly a lifetime of watchful selection, have produced beautiful flowers of large size and handsome habit. Stalks a foot long and individual blooms two inches across are by no means uncommon, and yet there is nothing of coarse appearance about the flower. Among the whites and yellows alone there is an extraordinary variety of detail, which, while it is not apparent in the mass, makes the plants extremely interesting as individuals; hardly any two that may be seen near together have the same physiognomy. The disparity is mainly in the form and disposition of the petals, for some are smooth-edged and others largely or finely notched; some are round and clear while others are imbricated; some are flat and others waved.

The old florists' distinction of pin-eye and thrum-eye also alters the character of the flower, for though it is not noticeable or of any importance when the plants are seen in the mass, yet, when the individual bloom is observed, the single flower and the whole charm gain by the thrum-eye, where the anthers rise above the pistil and form a symmetrical centre, and especially when this is further enhanced by a raised, fretted ridge at the edge of the tube, forming a kind of crown and giving the flower what is called a pin-eye. In the pin-eye the pistil rises above the anthers and shows alone, and the more ornamental detail is wanting.

In a woody garden where some thousands of these bunch primroses are grown the effect is extremely striking. The yellows have developed to a tint of the deepest orange, which gives great richness to the mass of full yellow-colouring and additional value by contrast to the tenderer tones of pale yellow and white that are seen in the more distant stretches of the garden.

At the time of fullest bloom the best are marked for seed, and every year some thousands of seedlings are raised; one portion of the garden being given to the divided plants and another to the seedlings. In the case of a good loamy soil the seed may be sown at once, but in lighter soils it is found better not to sow till spring. In stronger soils the plants may also stand two years if it is desired, though it is generally safer to divide yearly.

Auriculas.

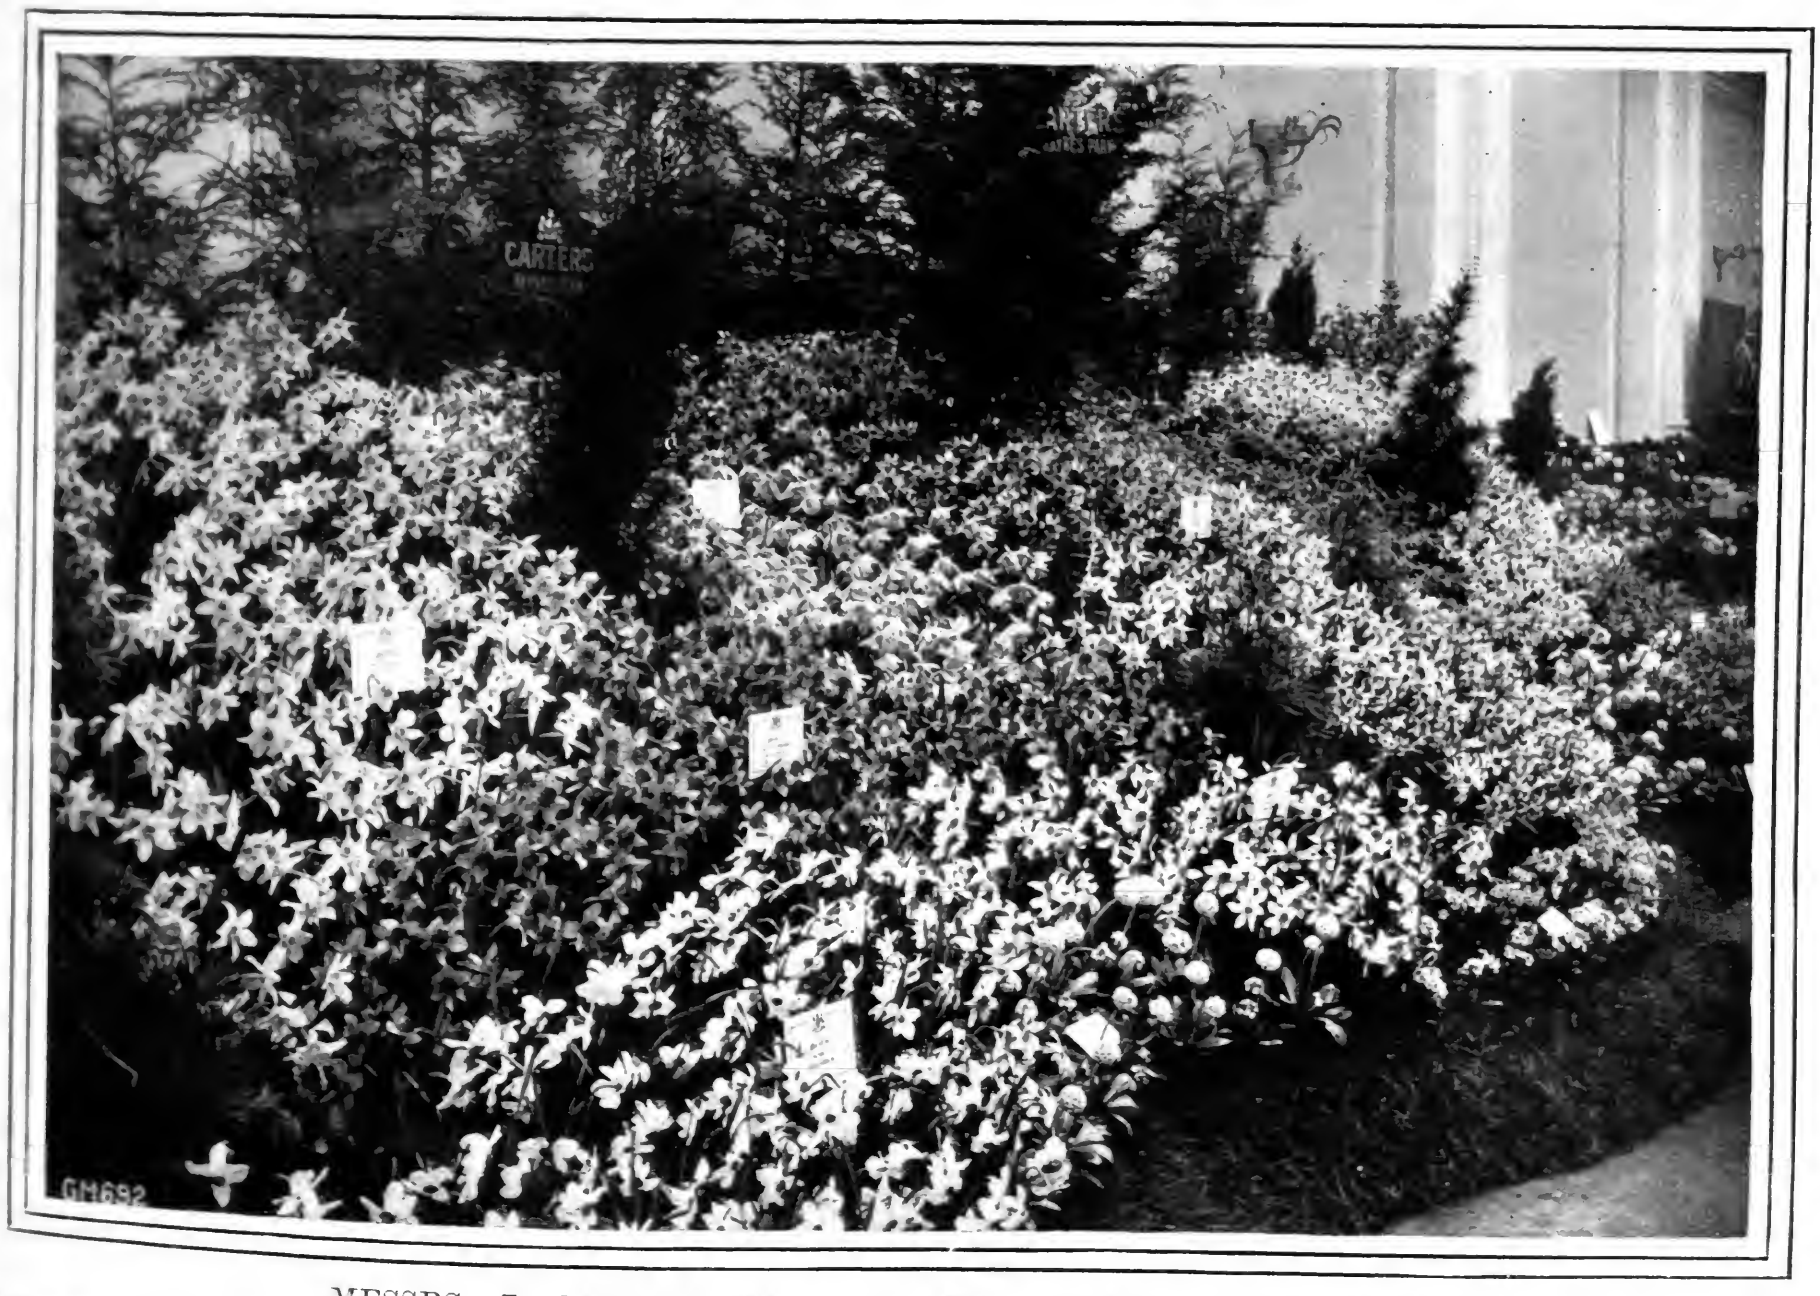
Border auriculas enjoy a rather stiffer soil, and especially one that contains chalk. They are derived from natives of the Alps and are in beautiful ranges of colouring of purple, crimson, and yellow. The border varieties are commonly called Alpine auriculas to distinguish them from the show kinds, though the name is ambiguous and even misleading, as there are several primula species of the auricula class, natives of the Alps, that are grown in rock gardens. The most showy and easily grown of the border auriculas are some very large forms having yellow and brown-bronze flowers with a white eye that have been raised in Scotland.

Primulas for Rockeries and Bogs.

The second group of primulas for popular use—namely, those best suited for rock gardens will partly overlap the first, for all the border auriculas will be in place in the lower rocky regions, while the best of the true alpine species with their white varieties and a number of natural hybrids, will find places in other cool rocky clefts and hollows. The prettiest of these will be among Primula Alloni, P. glutinosa, P. hirsuta, P. integrifolia, P. marginata, P. minima, and P. viscosa; the planter bearing in mind that some of these belong to the calcareous and some to the granitic regions. Thus P. auricula, P. integrifolia, and P. minima will be thankful for lime in any form and, for preference, limestone rock; while P. hirsuta, P. marginata, P. glutinosa, and P. viscosa will flourish in sandy peat with granitic rock or sandstone.

The primulas that, from the garden point of view, it is convenient to put in the third division are those that may be regarded as bog plants. These will include the pretty little P. farinosa of our own northern moors and of Alpine marshland, three Himalayan species, and one from Japan. The Himalayan are P. involucrata, a beautiful little primula, quite easy to grow and strangely neglected; the early-blooming P. rosea, with buds of brilliant crimson followed by the full bloom of rosy pink, and P. sikkimensis. This, when well grown in a fairly large mass rising from black boggy ground, and seen in shade, is a wonderful picture of plant beauty; the full heads of hanging sulphur bells having that curiously luminous quality that is only observed in this and one or two other flowers of this rare colouring. Lastly, of the well-known bog primulas there is P. japonica. The type colour is a rather strong magenta red, of a quality that does not please a critical colour-eye, but there is a good white variety and many intermediate shades of pleasing pink.

It is still well grown at Wisley, but it was a wonderful sight to see it for the first time some twenty years ago, when it was a comparatively new garden plant, as grown by the late Mr. G. F. Wilson, by the side of a shallow peaty ditch in shade in the lower ground. It showed a fine plant in good quantity, so placed that it could develop to the utmost its capacity for the display of beauty and the evidence of well-being. It was one of the many good lessons taught by Mr. Wilson that one is thankful to remember and glad to acknowledge.



MESSRS. J. CARTER AND CO.'S FINE DISPLAY OF DAFFODILS.

Arranged in a natural style at the exhibition held by the Royal Horticultural Society, April 15. The varieties represented in the arrangement were Albatross, Barri conspicuus, Beauty, Dazzler, Duchess of Westminster, Firebrand, Gloria Mundi, Homer, Incognita, Madame de Graaff, and White Lady.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SHADING.—With lengthening days the sun's rays grow stronger, and it is necessary to take every precaution against harm to the foliage. It is my experience that plants are more easily damaged by strong light in the spring of the year than at the close of the summer and during autumn. This is easily understood if we consider the dark winter period and the sappy nature of the growths, these latter being naturally more susceptible to injury than would be the case after the bright weather usually expected during the summer season. It is desirable then to let all the blinds down as soon as the foliage of the plants feels warm to the hand. In the cool division, not only the sun's rays, but also very bright light, must be reduced, and great care must be taken that the blinds are not removed from the roof too early in the afternoon, or the foliage of odontoglossums will become discoloured, ripen quickly, and decay, with the result that these will soon have a number of leafless pseudo-bulbs.

PERMANENT SHADING.—I consider for the north of England it is quite time enough to put permanent shading on the roofs after we are free from frosts and snowstorms. If the stippling is put on before then we find the first rain after a frost reduces the shading very considerably, and the work has to be done over again. This is undesirable, for unless the whole of the glass has been properly washed so as to remove what was put on before, the application of a second coat does not look well. It is necessary to whiten the glass between the divisions of the blinds, where they do not quite meet, as we find in most cases where lath roller blinds are employed for shading purposes, but it is desirable to put off covering the roofs until about the second week in May. We find whiting mixed with butter-milk and a little linseed oil makes good shading. This may be applied thinly to all the divisions. There is less risk of glaring light affecting the plants under these conditions, and it permits the blinds to be lowered later in the morning and drawn up earlier in the afternoon. All sidelights and gable ends of the houses should be permanently shaded now. A bright day should always be chosen for putting on the permanent shading.—H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

EUCHARIS GRANDIFLORA.—The stock of eucharis may now be overhauled and thoroughly cleaned, and should the bulbs be overcrowded in the pots, a number may be repotted. Place five or six of the best bulbs in a 9in. pot, or rather more of the smaller bulbs. The pots must be well and carefully crocked, for though when in full growth eucharis enjoys plenty of water, it will not endure stagnant soil. A suitable soil consists of good fibrous loam, a little peat, one-seventh of sand, and a little well-decayed manure. Pot firmly, just covering the bulbs, afterwards keep close and shaded, syringe well in bright weather, but withhold water from the roots until the plants are fairly active, and then apply carefully until the soil is well permeated with roots.

PANCRATIUM FRAGRANS.—This requires much the same kind of treatment and a similar soil to that recommended for eucharis. It may be flowered satisfactorily either grown singly in 6in. or 7in. pots, or three bulbs in a larger size. When repotting is contemplated it is well to do the work just after the commencement of growth. Offsets may be utilised for the increase of stock if this is desired.

CENTROPOGON LUCYANUS. — When rooted these may be potted up, and the plants treated as usually recommended for Plumbago rosea, excepting that only one or two stoppings will be necessary, for they naturally produce strong growths from the base which give fine flower spikes. As winter is approached watering must be more carefully attended to, for the plants are easily overwatered, and in such case roots are destroyed. For plants for house decoration, or for cut flowers for vases or table decoration, C. Lucyanus will amply repay careful attention.

ERANTHEMUM PULCHELLUM.—Where there is a demand for blue flowers in the winter months, this is a very serviceable plant, and if well grown and finely flowered it is very beautiful. Cuttings taken now root readily, and grown on steadily will make good stuff in 6in. or 7in. pots. Pinch the tips occasionally to ensure busy growth, and as the pots become filled with roots do not allow them to suffer from lack of nutriment. A later batch may be propagated for flowering in smaller pots.

COLEUS THYRSOIDEUS.—This is another valuable winter-flowering plant. Cuttings inserted as recommended should now be ready for potting, and if grown steadily and pinched occasionally, will make large specimens. Here, however, we find small plants the most useful. To obtain these a few are propagated, potted up, and stopped once. They produce three or four growths each, which are taken and inserted as cuttings, four or five inches in length, singly, in small 60's. When rooted they are potted into 48's, allowed to flower without stopping, and they produce spikes about eighteen inches in length.—H. Prime, Hatfield Gardens.

FRUITS UNDER GLASS.

PINES.—Queen pines that have received special treatment from early in the year will now be making rapid progress. Remove all galls from around the crown and base of the fruits, and reduce the suckers to one or two on each plant. Give sufficient weak liquid manure or guano water to well moisten the whole ball when required. The late cold, boisterous weather has rendered an even temperature almost impossible. It should be 75 deg. for mild, and 70 deg. for cold nights. Guard against having the water in the pipes very hot when there is a prospect of a sunny day, as this robs the house of moisture. It is necessary to exercise much care in this matter. Keep a watchful eye on the bottom heat to prevent it exceeding 90 deg., and slightly spray the plants overhead on bright days.

SUCCESSIONAL PINES.—These will now be making growth freely, and may be shut up with a temperature of 85 to 90 deg., well damping the walls, and floors, and lightly spraying the plants occasionally on bright days. Allow the temperature to gradually decline to 65 deg. for cold nights, and 70 deg. on mild nights by ten p.m.

MELONS.—Although the weather has not been severe, the absence of sun has rendered the liberal use of firing necessary, especially where fermenting materials have not been largely used in maintaining bottom heat and atmospheric moisture, the latter being the best of all preventives of red-spider. Feeding from this stage forward must be on a liberal scale until the fruits attain full size, and the more frequent the change of food the better the progress, and the finer the fruits. The night temperature should range about 75 deg. and by day from 80 to 85 deg., and 90 to 95 deg. after closing with sun-heat and a thorough syringing. Remove all useless sprays, and preserve every premier leaf, pinching laterals one leaf in advance of the fruit. Increase the temperature as the days lengthen, when air can be admitted freely. When in free growth, the plants will require liberal supplies of tepid water, stimulants being reserved for the swelling of the fruits.

FORCED CHERRIES. — As soon as the earliest varieties show signs of ripening, a somewhat drier atmosphere is necessary, and the houses will require ventilating as freely as may be consistent with the weather. Well mulch and water shortly before the fruits change colour, which will generally carry the trees over until the crop is gathered. Keep a sharp lookout for green or black fly, and fumigate when the foliage is quite dry when necessary.

PLUMS that were started rather early will now be swelling their fruits, which must be well thinned with grape scissors. Give preference to the fruits where there are most leaves. Mulching, feeding, and syringings must be continued for some time, as the earliest of these will have barely passed the stoning stage. Pure soft water only should be used for syringing as the bloom of these, like grapes, is easily damaged. Pay attention to grubs, and keep down aphis by occasional fumigations.—F. Jordan, Warter Priory Gardens, York.

THE FLOWER GARDEN.

HERBACEOUS BORDERS.—These will exact increased attention from now onwards, as the occupants are growing freely, and perhaps the most important detail connected with their management is giving support to the many subjects liable to become damaged by heavy rains and rough winds. Staking needs a certain amount of skill and judgment. It should be done artistically, and a good knowledge of the habit of the various plants is essential to enable the operator to carry it out. Nothing mars the effect of a border more than ugly stakes towering above a plant when it is in flower; stakes should be arranged so as to be as inconspicuous as possible, and this can be done by placing them in such a manner that growths can be tied in front of them, hiding them from view, and by judging the height of the stakes from the habit of the plant. Some objects will now need attending to in this direction, such as pæonies, lupins, delphiniums, and Oriental poppies, and unless this work is kept well in hand, it cannot be done to advantage, as once a plant becomes beaten down and left for a few hours nothing will induce the growths to grow back into their normal position.

EARLY FLOWERING CHRYSANTHEMUMS.—In recent years these have become deservedly popular, and no flower garden should be without a representative collection. Nonin's new introductions have provided us with some good varieties to choose from, which prove both interesting and useful additions to this already extensive class. In some localities it is only occasionally that plants remaining in the open ground will survive the winter, and rather than run the risk of losing the stock, old stools are lifted in the autumn to be propagated from. The young plants resulting from the practice will now be far enough advanced to plant out. The ground in which they are to be put must be previously well dug and enriched with rotten manure. As planting proceeds, each plant should have a stake put to it and receive a tie; this will prevent loss through the brittle stems becoming broken. A dressing of soot round each plant will do much to check the attacks of snails, which are very partial to them at this stage, and it also acts as a stimulant. Should the plants have been stopped once during their preparatory stage, they will not again require attention in this respect, but can be allowed to grow naturally. Any surplus plants may with advantage be planted in a reserve border, from which they can be lifted later on in the season, to fill gaps inevitable in herbaceous borders where use is made of biennials. With care they can be safely transferred to such positions until well on into the season, provided it is carried out during dull weather and plenty of water is applied to the roots until they have taken fresh hold.—T. B. Field, Wych Place Gardens.

ROYAL SHOW

BRISTOL,
July 1st to 5th, 1913.

THE ANNUAL EXHIBITION of HORSES, CATTLE, SHEEP, PIGS, POULTRY and FARM PRODUCE: JUMPING, HORSE-SHOEING and BUTTER-MAKING COMPETITIONS, AGRICULTURAL EDUCATION, FORESTRY and HORTICULTURE.

HORTICULTURE
ENTRIES CLOSE MAY 31st
(Live Stock entries close May 20th).

Prize Sheets and Entry Forms will be forwarded on application to

THOMAS McROW, Secretary.
ROYAL AGRICULTURAL SOCIETY OF ENGLAND,
16, Bedford Square, London, W.C.

WOLVERHAMPTON
GREAT FLORAL FETE,
JULY 8th, 9th, and 10th, 1913.
Over £900 in Prizes.
Schedule on application to the Secretary (post free),
C. F. AMPHLETT, 80, Darlington St., Wolverhampton.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The following are the awards made to new plants and other exhibits at the show held by the Royal Horticultural Society on the 15th and 16th inst.:

CERTIFICATES AND AWARDS.

First Class Certificate.—To Lælio-cattleya Luminosa Holford's var., and to Odontoglossum Pescatorei Lady Holford, from Lieut.-Col. Sir George Holford (gardener, Mr. H. Alexander), Tetbury, Gloucestershire; to Narcissus Mrs. Ernst Krelage, from Messrs. L. H. Krelage and Son, Haarlem.

Award of Merit.—To Narcissus Europa, from Messrs. Walter T. Ware, Lim., Bath; to Narcissi Cædmon and St. Olaf, from Messrs. Barr and Sons, Covent Garden; to Hippastrum Eurasian; to Primula Maximowiczi and to Androsace tibeticum, all from Messrs. Jas. Veitch and Sons, Chelsea; to Primula viscosa Beauty and Auricula Suffragette, from Mr. Jas. Douglas, Great Bookham; and to Helichrysum bellidoides, from Mr. A. Hemsley, Crawley.

MEDALS.

Gold.—To Messrs. Sutton and Sons, Reading, for early vegetables.

Silver-gilt Flora.—To Messrs. Barr and Sons, Covent Garden, for daffodils; to Messrs. R. H. Bath, Lim., Wisbech, for daffodils and tulips.

Silver-gilt Banksian.—To Messrs. J. Veitch and Sons, for azaleas, primulas, etc.; to Mr. A. M. Wilson, Shovell, for daffodils.

Silver Flora.—To Mr. Barclay, Spetchley, for primroses; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. B. R. Cant and Sons, Colchester, for roses; to Mr. Maurice Prichard, Christchurch, for hardy flowers; to Mr. C. Bourne, Bletchley, for daffodils and tulips; to Mr. S. Florey, Tracy's Nursery, Twickenham, for orchids; to Mr. E. H. Davidson, Twyford, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; and to Messrs. Charlesworth and Co., Haywards Heath, for orchids.

Silver Banksian.—To Mr. Jas. Box, Limpsfield, for rock garden; to Messrs. H. Cannell and Sons, Swanley, for pelargoniums; to Messrs. Wm. Cutbush and Son, Highgate, for roses and carnations; to Mrs. Jas. Douglas, Great Bookham, for auriculas; to Messrs. H. B. May and Sons, Edmonton, for ferns, etc.; to Mr. G. Prince, Longworth, for roses; to St. George's Nursery Company, Uxbridge, for calceolarias; to Messrs. Sutton and Sons, Reading, for cinerarias, and also one for daffodils; to Messrs. Hassall and Co., Southgate, for orchids; to Mr. A. H. Metcalfe, gardener to Lady Wernher, Luton Hoo, for forced strawberries; to Messrs. J. R. Pearson and Sons, Lowdham, for daffodils; to Robert Sydenham, Limited, Birmingham, for daffodils; to Messrs. J. Carter and Co., Raynes Park, for daffodils; to Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to "Lissadell," Sligo, for daffodils.

Bronze Flora.—To Messrs. T. S. Ware, Lim., Feltham, for rock garden.

Bronze Banksian.—To Messrs. Barr and Sons, Covent Garden, for rock garden; to Messrs. G. and A. Clark, Dover, for primroses, etc.; to Mr. Day, for irises; to Messrs. R. Gill and Sons, Falmouth, for rhododendrons; to Messrs. Stuart Low and Co., Enfield, for acacias, etc.; to Messrs. Wm. Paul and Son, Waltham Cross, for rambling roses; to Messrs. Phillips and Taylor, Bracknell, for auriculas, etc.; to Mr. G. Renthe, Keston, for rhododendrons, etc.; to Mr. L. R. Russell, Richmond, for clematis; to Wargrave Plant Company, The Arcade, Liverpool Street, for rock garden; and to Messrs. Reamsbottom and Co., Geashill, Ireland, for anemones.

London Daffodil Show.

The great pressure on our space in our last issue rendered it necessary to leave over a portion of the report of this interesting exhibition, and we have now the pleasure of giving the portion that was left over.

Six Barri varieties were represented by four exhibitors, Mr. S. F. Staffurth leading off with clean examples of Crown Prince, Cresset, Glitter, and Firebrand; Mr. H. R. Darlington was second, and the Rev. T. Buncombe third. The six varieties of Leedsi made a brave show. Here Mr. H. R. Darlington was again successful. His varieties were in fine condition, the best being White Lady, Waterwitch, White Countess, and Selene. Mr. S. F. Staffurth followed with Longfellow, very fine, Diana, and Evangeline; while the Rev. T. Buncombe brought up the rear.

For twelve varieties, three stems each, Mr. R. Morton, Grange Dene, Woodside Park, won well. His best vases were Lady Margaret Boscawen, Maggie May, and Lucifer; the Rev. Canon Fowler, Earley Vicarage, Reading, was second with clean, well-developed flowers; and Mr. G. Stocks, Doncaster, third. Mr. R. Morton was first for three trumpet varieties, the varieties Van Waveren's Giant and King Alfred being in perfect form. The same exhibitor was the only competitor in the next four classes, and was awarded firsts, seconds, or thirds, as the judges thought necessary to meet the case. The Rev. Canon Fowler gained a second prize for three Incomparabilis varieties, while Mr. R. Morton secured the prizes for both classes of the Barri section.

For twelve daffodils, distinct, introduced into commerce during or since 1909, Mr. C. Bourne was placed first, staging some fine examples of Lemon Belle, Queen of Hearts, Miss Willmott, Red Eve, and Evensong. Mr. F. H. Chapman was second, while three entrants appeared to exhibit twelve varieties not yet in commerce, Mr. E. M. Crosfield won first prize with some charming varieties, the chief being Discus, Touchstone, Mowglie, Bayards, Ibex, Loki, and Willonyx; Mr. W. Welchman, Upwell, Wisbech, was second, staging some fine trumpet varieties, Hereward, Dreamland, King Cyrus, The Commonwealth, and Lord Cromer being quite the best; Mr. F. H. Chapman being third.

Mr. C. Bourne led off for six varieties not in commerce, Barbara, Imperialist, and Stephen Phillips being really fine; Messrs. W. A. Watts and J. Mallender, Scrooby, Bawtry, following in the order named. For three varieties, Messrs. Cartwright and Goodwin were the only exhibitors, and were awarded second prize. The new Triandrus varieties not in commerce secured three entries, Mr. E. M. Crosfield winning with some fine white varieties, but only one of the twelve white varieties; Mr. W. A. Watts followed, also with unnamed seedlings; while Mr. F. H. Chapman brought up the rear again.

Mr. A. M. Wilson, Shovell, Bridgewater, was placed first for six seedling varieties, Gascon, Miami, Harpagon, and Anicet being remarkably fine; Mr. P. D. Williams, St. Revene, Cornwall, was placed second with Lysander, Hornet, and Susan as conspicuous varieties; Mr. W. Welchman was third. Mr. W. A. Watts won first prize for three seedlings raised by the exhibitor, the varieties were St. Asaph, Mercury, and Aden; Mr. T. Batson, Bedworthy, Devon, was second. The classes for single blooms were well filled, and attracted much attention from the exhibitors as well as the visitors, but many of the varieties seemed to be under number only.

Kent, Surrey, and Sussex Daffodil Society.

The seventh annual exhibition took place on April 17 in the Great Hall, Tunbridge Wells. On the whole, the display was not quite so good, nor the standard of excellence so high as on previous occasions, due undoubtedly to the unparalleled vagaries of the season. The opening of the show was greeted by a thunderstorm, accompanied by heavy rain and hail, the latter conditions prevailing best part of the afternoon. Non-competitive exhibits assisted largely in the matter of attraction, the two most conspicuous being the stands of daffodils put up by Messrs. Barr and Son, and Mr. F. Herbert Chapman. The former contained many choice blooms of new and rare varieties, whilst the latter displayed a goodly number of magnificent blooms of unnamed seedlings, in addition to other choice varieties.

In the competitive classes, J. A. Nix, Esq., won the first prize, and silver challenge cup, to be held for one year, for a collection of daffodils, consisting of ten varieties of each of the three groups, viz., Trumpet, or Magni coronata, Chalice-cupped, or Medio coronata, Saucer or flat-crowned (Parvi coronata), including varieties of poeticus, one vase only of each sort with three stems of bloom. Contained in this collection were fine blooms of Mrs. G. H. Barr, Henri Vilmorin, Cygnet, Rev. D. R. Williamson, Weardale Perfection, and Monarch representing the trumpets; Pilgrim, Lucifer, and Gloria Mundi, the chalice-cupped; Red Beacon, Kingsley, Incognita, Ibis, Horace, and White Lady those of the saucer or flat-crowned. C. G. A. Nix, Esq., was second. For twelve distinct single varieties, representing the three groups as above, Miss A. L. Nix secured premier award, showing Rev. D. R. Williamson, Monarch, Will Scarlett, Red Beacon, Cassandra, Weardale Perfection, Royal Star, and Horace; Miss V. Warren second.

For six distinct single varieties of true trumpet daffodils, three stems of bloom of each, Miss V. Warren took premier award, followed by Miss E. D. Roberts. Miss Warren also secured premier award for six distinct single poeticus varieties, showing very fine blooms of Scholar, Lonata, O. W. Holmes, Cowper, J. Godfrey Saxe, and Kingsley; Mr. W. Bull being second. For the finest single bloom of trumpet daffodil, C. A. J. Nix, Esq., was first with Mrs. G. H. Barr; Miss A. L. Nix second with Weardale Perfection; and Miss V. Warren third with Yellow Knight. C. G. A. Nix, Esq., scored with Maid of Athens, for the finest single, chalice-cupped bloom; Miss V. Warren second with Hon. Mrs. Frecklin; J. A. Nix, Esq., and Miss A. L. Nix equal third with Will Scarlett. For the finest single Parvi coronata bloom, C. A. J. Nix, Esq., led with Red Beacon, followed

J. A. Nix, Esq., with the same variety; and Miss V. Warren third with Ivy Nunn. J. A. Nix, Esq., scored for the finest bloom of poeticus, followed by Miss Warren, both showing Kingsley; C. G. A. Nix, Esq., third with Homer.

The premier award for the finest single stem of bloom of an obvious triandrus hybrid, fell to Miss Warren for Maid of Kent. Miss Warren was also successful in the class for three distinct varieties of seedling narcissi raised by the exhibitor, but not in commerce, showing exceedingly fine blooms of Etheldreda, Kent, and John Gunn Warren.

Broughty Ferry Horticultural Association.

The April meeting was held under the presidency of Mr. James Bethel in the Y.M.C.A. Hall. "Practical Hints on Exhibition Roses" was the title of a lecture delivered by Mr. John Simpson, head gardener to the Earl of Dalhousie, at Panmure House. The lecturer clearly defined his methods of cultivation from the process of budding on the seedling briar until the dressed bloom was under the critical eye of the judge. A south-west aspect was advised, and deep, well-drained loam, inclined to be stiff, was the ideal soil. November planting was best. Pruning, as soon as growth was visible in spring, he described as thinning-out the weak, and cutting-back the strong shoots to about three eyes from the base. Hoeing, disbudding, and insect pests, as well as fungoid diseases were all touched upon; while a list of the best roses for exhibition purposes was given. The lecture was well received, and his remarks evoked considerable discussion.

The monthly prize was voted to Mr. D. K. Meston, The Lodge Gardens, for a well-flowered Dendrobium thyrsiflorum. Other exhibits consisted of a good example of Cattleya hybrida and Dendrobium densiflorum from Mr. Alex. Duncan, Carbet Castle Gardens, roses and seedling carnations from the lecturer, and a malformed arum from the President.

United Horticultural Benefit and Provident Society.

The monthly meeting of the above society was held in the R.H.S. Hall on Monday, April 14, Mr. Charles H. Curtis in the chair. Five new members were elected, and two members were allowed to withdraw £5 16s. 9d. and £5 respectively from their deposit accounts; fifteen members were also allowed to withdraw double the amount of interest, amounting to £59 13s. 6d. The sick pay for the month on the ordinary side amounted to £60 5s. 6d., and on the State side, £23 5s. 10d.; while maternity claims came to £12. The sum of £5 18s. 10d. standing to the credit of a member who lapsed thirty years ago was passed for payment.

The adjourned annual meeting will take place on May 5, when the report and audited financial statement will be placed before the members.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

Norfolk and Norwich Spring Show.

This event was originally fixed for April 24, but late in February the committee could foresee that the season would be early, so altered the date to the 17th. The fickleness of the weather, however, caused another setback, for on the night of the 11th the district was visited by the heaviest fall of snow for the year, causing much havoc among the narcissi and outdoor flowers in general. Nevertheless, some of the growers of the district were able to stage very good blooms, even though these had been down to the ground under snow.

At the outset we must congratulate Mr. George Davison, Westwick House Gardens, for his contribution to the show. He won all the first prizes possible for narcissi, and secured a gold medal for a batch of seedlings. He has made a name for montbretias, but when one saw these glorious trumpet flowers of his—they were staged without name or number, so we cannot individualise—one wondered how he had succeeded. King Alfred, Glory of Leiden, Madame de Graaff, and others were simply not comparable with some of these seedlings when placed side by side with them. Much more will be heard of these in the future. Mr. H. Woodhouse, gardener to Sir Herbert Cozens Hardy, staged a very fine up-to-date lot of all varieties, and took several prizes. Mr. Frank Neave, Lingwood, was a notable exhibitor also in this class, and likewise took first place for herbaceous flowers.

Tulips, polyanthus, pansies, violets, and flowering shrubs were also much in evidence. In the latter class Mr. J. Notley, gardener to E. G. Buxton, Esq., Catton, had a splendid exhibit, and was easily first. This exhibitor also came out well in the pot plant section, securing a meritorious first for a group of flowering and foliage plants, first for roses in pots, first for mignonette, and first for a single foliage plant. Mr. E. Greene, gardener to Edmund Reeve, Esq., Catton Grange, had the best cinerarias, schizanthus, pelargoniums, and rambler roses, the plants doing the grower great credit. He was the only exhibitor of strawberries, and had well-berried plants with good size and colour.

Salads and vegetables were not a strong feature. Mr. E. Greene had a well-arranged basket, and the best cucumbers were staged by Mr. W. Joice, a local grower. He also had the best tomatoes, the variety being Holmes' Supreme.

The best educational feature of the show was the trade contributions. Messrs. Daniels Bros., Lim., Norwich, had a varied display which brought them many compliments. It comprised roses in large numbers and great variety, forced shrubs of all kinds, lilies, pelargoniums, schizanthus, and alpine and rock plants in profusion, with a variety of choice cut flowers as a centre effect.

Messrs. Hobbies, Lim., Dereham, made a display worthy of the traditions of this firm. Roses, as one might expect, were much in evidence, but other things were not omitted; clematis, of many hues, were good, so were the lilacs, laburnums, and Pyrus malus.

Messrs. A. J. and C. Allen, Norwich, had a most creditable exhibit of all kinds of roses in pots, ramblers, polyanthas, teas, hybrid teas, and briers each being represented. Messrs. R. Wallace and Co., Colchester, set up such a display of saxifrages, aubrietias, primulas, and hosts of other rock garden flowers that seemed to fascinate a crowd of admirers all the time. Mr. R. C. Notcutt, Woodbridge, showed to the best advantage the utility of early forced standard shrubs, and most judiciously incorporated palms, acers, and other foliage plants. Mr. G. W. Miller, Wisbech, made a pleasant display, primarily of orchids in many types, but helped greatly also by his alpines and other hardy flowers.

The secretary, Mr. C. E. Pilling, and the executive are to be congratulated upon the arrangements. There was just a slight falling off over the previous year in attendance, due, no doubt, to a big counter-attraction.

French Horticultural Society of London.

The annual dinner of this useful society took place at the Cafe Royal, Regent Street, London, on Saturday, April 19, when Mr. P. Rudolph Barr presided over a record attendance. Many prominent horticulturists were present, including Sir Harry J. Veitch, Sir Albert Rollit, Mr. N. N. Sherwood, Mr. George Barr, Mr. C. Harman Payne, Mr. G. Schneider, Mr. J. F. McLeod, Mr. W. Howe, Mr. A. Dimmock, Mr. T. Bevan, Mr. D. Ingamells, M. Hiehle, M. Ripard, Mr. C. H. Curtis, Mr. Tivey, Mr. Giles, etc.

The function was a most pleasing one. The Chairman made a capital speech, dealing chiefly with the great influence for good the society exerted upon young continental gardeners, who came over to England to learn our language and extend their knowledge of horticulture. Mr. Barr induced nine or ten friends to become honorary members during the evening. Sir Albert Rollit responded for "Horticulture," and spoke in his usual interesting and humorous fashion. Mr. G. Schneider, its founder, responded on behalf of "The Society," and he was the recipient of a very handsome clock, presented by young members of the society. M. Ripard and M. Sansy spoke, and Mr. C. H. Curtis responded for "The Press." Mr. Dimmock replied for "The Visitors," and both Sir Harry J. Veitch and Mr. C. Harman Payne were called upon for speeches, and each delighted the audience. Mr. G. Cuthbert gave "The Chairman." Everything went off well, there was plenty of good music, and nearly everyone stayed to the end of a long programme.

Dumfries and Galloway Gardeners' Association.

A large attendance and a capital paper marked the last meeting for the present session of this association on April 19. Mr. S. Arnott occupied the chair, and introduced the lecturer of the evening, Mr. Wm. Hutchinson, The Gardens, Terregles, Dumfries. His subject was "The Malmaison Carnation," and the essayist, who has had a long experience of this flower, and who cultivates it with marked success, gave an admirable account of the origin and rise of this class of carnation, together with full details regarding its management in its various stages. Mr. Hutchinson expatiated concisely and well on the great value the Malmaison possessed for decorative and other purposes, and pointed out how valuable it proved to the gardener in many ways. The cultural details were very fully, yet succinctly, stated, and a résumé of the various points, such as propagation, the best houses, composts, potting, drainage, temperature, manuring, and the treatment of diseases, was given in an able manner; while the several treatments required for plants in their first, second, third, and even fourth years were detailed. Mr. Hutchinson finding old plants useful for the supply of late blooms. A list of the best varieties was also given.

Mr. D. Hunter, hon. secretary and treasurer, made an interim statement of the membership and financial position, this being of a satisfactory character in every way. Consideration was taken up of the proposed summer excursion, and a remit made to a committee; while it was remitted to the ordinary committee to make arrangements for the new session, the general meeting to be held in September.

Gooseberry Bushes.—These, on poor soils, will be greatly benefited by having good soakings of liquid manure at intervals, especially if the berries are expected to grow to a good size. Gooseberries are not infrequently found growing in a somewhat out-of-the-way spot, but for the production of good fruits yearly they, like other fruits, require good cultivation and attention. Top dressing and the timely thinning of the bushes are items that should not be neglected, and the same remarks apply to red and black currants.—H. Markham.

NOVELTIES AND RARITIES AT BEES' NURSERIES.

"There is nothing new under the sun." Thus it has been written, but, nevertheless, every horticultural enthusiast takes a keen delight in discussing the "new things" he discovers, or acquires, and is ever eager to learn from others of the latest introductions, whether they emanate from distant lands or from the hands of hybridists and plant breeders at home.

We need not split straws to insist on the technical inaccuracy of calling a plant "new," that has inhabited far-off lands for centuries, for it is from a practical point of view only reasonable to base our calculations upon the date of introduction into Britain, and we have during the past few years received a very large number of new introductions, particularly from China, the majority of the plants sent from that vast country being sufficiently hardy to thrive under the conditions prevailing in the British Isles.

Within the past ten years our gardens have been enriched in a wonderful degree by the new plants discovered and sent home by Wilson, Forrest, Purdon, and Kingdon-Ward, and many of these newcomers have already made themselves thoroughly at home in gardens in every quarter of the British Isles, whilst there are many more good things of which stock is being worked up in the nurseries from whence the travellers went forth, and these will be put into commerce in the near future. The floral wealth of China is apparently inexhaustible, for, as was shown by Professor Balfour at the recent Primula Conference, that we have, despite the large number of primulas explorers have sent us, only touched the fringe of Chinese primulas, to say nothing of the many other families of plants that await the attention of those whose enthusiasm and courage urge them to renewed effort for the benefit of British horticulture.

The Sealands Nurseries, which belong to Messrs. Bees, Lim., are extensive (about 300 acres), and devoted mainly to the cultivation of hardy perennials and roses, and it is here that the plants are to be found that Mr. George Forrest sent home as a result of his first two expeditions to China, while more recently Mr. Kingdon-Ward has sent further consignments of seeds gathered during a successful journey in the interests of this progressive and enterprising firm.

Readers of THE GARDENERS' MAGAZINE already know a good number of the earlier introductions, among which were the exquisite Primulas Forresti, Bulleyana, Littoniana, and malacoides, as well as Incarvillea brevipes, Potentilla Veitchi, which both Mr. Forrest and Mr. Wilson sent home, as, too, was the case with Meconopsis integrifolia.

It will not be long before a good many other plants which I saw at Sealands will be as widely known and largely grown as any of those I have just mentioned, for they have only to be seen to win the affections of any hardy plantsman. Of the primulas it would be difficult to say definitely which is the choicest or most beautiful, but Primula sikkimensis will, at any rate, find general favour. It is a plant of robust, vigorous growth, some eighteen inches in height, with bright glassy foliage, and it bears an abundance of glowing purple-crimson flowers in whorls. The individual flowers measure an inch or more across, so that a colony of half a dozen plants in full flower will make a splendid display of brilliant colour. Some of the prettiest primulas are rather difficult to bring through an average English winter, being impatient of dampness during their resting period, but P. angustidens is not one of these. It will thrive like a polyanthus.

Equally interesting in its way is P. secundiflora, which may briefly be described as a purple P. Sikkimensis. The exact colour is not easy of description in writing, for, although it has not a velvety sheen, it is a rich shade, with depth in it, that prevents any unpleasant impression such as an ordinary dull purple induces. The modest drooping bells, nodding in the faintest breeze, are produced in abundance on tall, perfectly erect stems, and they are delightfully fragrant.

Totally distinct from either of the foregoing, and, in fact, quite unlike a primula, so far as form of flower is concerned, is P. muscarioides, a valuable acquisition to any collection of primulas, if only to demonstrate the remarkable variety in form and colour that exists in a single genus. P. muscarioides ranks among the tiniest of them all, but it must not straightway be assumed that it is a "miffy" little plant, that demands incessant care and effort to keep it in existence. It is hardy and good-tempered, and, although a miniature, its little flowers are of so rich a purple that it is quite attractive, whilst the grape-hyacinth-like shape and arrangement of the flowers is a feature that makes one take a second glance at the label, with a mental query, "Is this a primula?"

Then there is Primula pulchelloides, the foliage of which would justify the name persicifolia. This also has nodding flowers in the way of P. Sikkimensis, the colour being lilac verging to a rosy-mauve. The whole plant is coated with yellow meal or farina, adding another note of distinction to an extremely interesting plant. Space will not allow of detailed eulogies of P. farinosa Beesi, P. Beesiana, and other members of the family, for there are so many other subjects that claim attention.

It may, perhaps, appear strange to give first place to a plant of which I have not yet had the pleasure of seeing flowers, and which, indeed, has not bloomed in its new home, but Incarvillea lutea has such outstanding claims for notice that I must deal with it before turning my thoughts in other directions. The fact that Mr. Forrest was enabled to send home a good photograph of a specimen flowering freely in its native habitat puts me on safe ground, for this photograph affords convincing proof that here we have a real aristocrat among hardy plants. A strong plant, of noble proportions, is depicted having five or six tall, erect stems, bearing handsome flowers, which Mr. Forrest tells us, are of a fine shade of yellow. The plants growing at Sealands have leaves from two to three feet in length, and the health and vigour of these young plants augur well for their conduct when they reach the flowering stage. Readers of THE GARDENERS' MAGAZINE who have seen the reproduction of Mr. Forrest's photograph of Incarvillea lutea, which appears in Messrs. Bees' catalogue, will readily agree with me that this plant will long retain a high place in our affections.

Delphinium yunnanensis adds another member to this popular family, and it is one that possesses characteristics distinctive enough to prevent likelihood of its confusion with its relatives. The foliage of the plant is cut and splashed with greyish-white after the manner of some of the eryngiums. It produces grand blue flowers, and is a plant that should prove very useful to the plant breeder, as well as being an interesting addition to our collections of larkspurs. Not yet ready for distribution, but worth waiting for, is a very neat little plant named Didissandra lanuginosa. Its foliage resembles a ramondia, while its flowers are of similar form to those of haberlia. I cannot vouch for the hardiness of this pretty little subject, but let us hope it may prove equal to our trying climate, and, at any rate, if it should be necessary to give slight protection during winter, it is well worth the trouble.

It often happens that a dry, sun-baked spot in a garden causes its owner some anxiety to find something in the way of plant life that will clothe the earth with verdure, and for such a purpose Ephedra Gerardiana Sikkimensis may well be recommended. It is free-growing, with wiry stems, of rush-like appearance, and in autumn it bears innumerable tiny scarlet flowers, nesting in the angles and joints of the foliage, and, whether on exposed parts of a rockery, on a dry wall, or a steep bank, the trailing growths and bright-coloured flowers are calculated to make presentable what might otherwise be bare and uninteresting patches. Codonopsis meleagris, Dracocephalum tanguticum, and Buddleia macrostachya yunnanensis have already been described and figured in these columns, and readers have also either seen or heard of that lovely plant Roscœa cautlioides, which was one of the most interesting of the new plants exhibited at the International Exhibition last year. It is good to know that plants have come well through the past winter without protection at Sealands—a spot, by the way, that is well adapted to test the hardiness of either man or plant, and we may, therefore, predict that before many years we shall see the shimmering, satiny, charmingly tinted flowers of Roscœa cautlioides in every collection of hardy plants that lays claim to be at all representative, for it is totally different from anything else we have, although, to a certain degree, it resembles an iris in general appearance. I do not know any plant which can be compared with it for the exact shade of its yellow flowers, for they are neither primrose, sulphur, nor canary, but are of a truly delightful shade.

It must not be supposed, despite the great attention Messrs. Bees, Lim., have devoted to Chinese plants, that novelties from other countries have been ignored, for that would be entirely erroneous. A New Zealand plant that is all but hardy in this country—requiring a sheet of glass to ward off winter rains—is Celmisia grandiflora, with big rosettes of thick hoary foliage and large daisy-like white flowers. Then there is Celmisia spectabilis argentea, which was another of the novelties the firm showed at Chelsea, and has stood the winter at Sealands with just handlight protection during wet weather. The silver-leaved Lupinus argenteus is a shrubby plant that claims more than passing notice. The leaves are small, but plentiful, and both they and every part of the woody stems are clothed in whi

CANARY GUANO

FOR GARDEN AND GREENHOUSE.

There is no Fertilizer equal to Canary Guano for the Garden and Greenhouse. Compare its results, its analysis, and its fine condition with any others, and you will be convinced of this. Canary Guano immensely improves the colour and size of all Flowers, and doubles the yield of all Fruit and Vegetables. It is particularly suited to lawns, golf greens, and cricket grounds. Canary Guano is manufactured by The Chemical Union, Ltd, in conjunction with their associated company, Joseph Fison and Co., Ltd, Ipswich, Fertilizer Manufacturers to the King, who are the largest Special Fertilizer Manufacturers, and whose goods are used all over the World.

CANARY GUANO is sold by Seedsmen, etc., in tins and bags, from **6d.** to **20s.**

Be sure and purchase "Twentieth Century Gardening," by John Weathers. 300 pages. **1/-** nett. To be obtained of all Booksellers.

If unobtainable, sent post free on receipt of P.O. 1/4

Full particulars from

THE

CHEMICAL UNION, Ltd, IPSWICH.

and the flowers, borne in spikes of good length, are lavender-blue and white. It is good to learn that propagation is proving easy, and fine batches of young plants are coming along, doubtless to find a very ready sale, for it is a subject that only needs to be seen to be appreciated. Oxalis adenophylla, which was illustrated and described awhile since in these pages, is another gem that is destined to become widely grown, and Weldenia candida, shown in the set of new and rare rock plants that won the Farrer Cup for Messrs. Bees, Lim., is accurately described in their catalogue as possessed of "beauty of quite an extraordinary character." At present, limitations of stock compel almost a prohibitive price being asked, but when a little cheaper there will be a big demand for this little gem, with its rosette of pale green leaves and glistening white flowers that resemble the blossoms of a wide-open crocus.

For several years Messrs. Bees, Lim., have had hybridists at work among various kinds of plants, and they have many excellent things in store both among alpine and border plants, and also a number of promising roses.

Viola gracilis has been occupying attention of late, and some of the hybrids and selected forms I saw when at the nursery are vast improvements on the type, excellent as it is.

For some years the writer has held the opinion that if the alpine mimulus were taken up and carefully fertilised and selected we should soon have an entirely new and infinitely lovely race of easily-grown and wonderfully-prolific plants suitable for rockeries, beds, borders, or waterside. Messrs. Bees, Lim., have had the task in hand, and results are satisfactory in the highest degree, for they are placing on the market a set of really lovely hybrid mimulus which produce large flowers of distinct and beautiful colours. Being true hardy perennials these should become widely distributed and largely grown.

Brief reference must be made to a set of dwarf rhododendrons that are suitable for rock culture, named R. myrtifolia, R. arbutifolia, R. daphnoides, and R. hirsutum. These are all of neat, compact habit, and just the style of flowering shrub required for prominent positions in the rock garden. Another handsome and distinct rhododendron noticed is R. bullatum, which has very effective reticulated foliage, the underside being covered with a showy golden-brown, felt-like tomentum. The plant has come from China. A climber of Mr. Forrest's introduction is Jasminum Beesianum, which bears bright cherry-red flowers, and has large, almost leathery, foliage. Visitor.

TRADE NOTE.

A box of delightful perpetual carnation blooms from Mr. C. F. Van der Sluys, La Ramée, Guernsey, reminds us that with the increase of spring sunshine such carnations are now at their best. The box included finely-coloured, well-filled, and substantial flowers of Marmion, Rose Doré, and Rose Pink Enchantress, as well as very clear blooms of White Perfection and White Enchantress. We have greatly appreciated the beauty and fragrance of these flowers.

CATALOGUES RECEIVED.

BARR AND SONS, COVENT GARDEN.—In this firm's new catalogue of hardy perennials, alpine, and aquatic plants, selections for various positions in a garden are given, but otherwise the plants are listed in alphabetical order, with a few pages specially devoted to new and rare plants.

G. COOLING AND SONS, BATH.—Collections of seeds for gardens of various sizes are a feature of this firm's spring catalogue. Illustrations are numerous and good, and there are useful lists of sundries and of bulbs for spring planting.

A. F. DUTTON, IVER, BUCKS.—A most attractive booklet showing the great extent of the carnation industry at Iver. Border, perpetual, and Malmaison varieties are listed, and collections of varieties are arranged for amateurs. The illustrations are excellent, and the variety Mrs. A. F. Dutton figures in colours on the front page.

ANSWERS TO CORRESPONDENTS.

LEVELLING RIDGE AND FURROW PARK LAND.—E. W., Northampton.—I shall be glad of your help in the following matter. We have a park which was once an arable field. Before being sown down it was thrown up in ridges for drainage. My employer does not like the appearance of the part, and so I want to know the best method of removing the ridge and furrow appearance without destroying the turf.—Leave the turf alone until next September, meanwhile arranging to deal with the matter as early as possible during that month. Work up a large stock of fine rich soil, and see that sufficient tools, planks, etc., are ready when the time arrives, so that the work may be done as expeditiously as possible. Decide upon the level to be followed, because if the ridges are filled into the furrows the general level will be lowered. Remove the turf and dig or plough a given area at one time; digging will be best, as it will make levelling an easier matter. Add the new soil previous to raking and levelling, make all firm, and re-lay the turf. Roll well, and spread fine soil over the turf, working it into the joints of the turves with a stiff broom. If everything is carefully planned out beforehand a very large area can be dealt with in a comparatively short time. If expense is no object the work could be done at once, but if a hot, dry season followed, a great deal of the turf would be killed unless special arrangements were made for watering on a large scale.

CULTIVATION OF THE VALLOTA.—W. S., Streatham: Some of our young men would be greatly obliged if you would kindly publish an account of the best method of cultivating Vallota purpurea (the Scarborough Lily). This plant seems to be a very troublesome one to grow successfully in this district, therefore I feel sure you will come to our aid.—Vallota purpurea is a greenhouse plant—indeed, it is almost hardy, hence any attempt to treat it as a stove plant will certainly lead to failure. As a general rule potting is done about July, a little while before the spikes begin to develop, and when new roots are being formed; but the finest examples we have seen were from bulbs potted in January. These were potted every second year, part of the stock being dealt with each season. The bulbs were shaken from the old soil and all small ones removed, the flowering size being repotted, placing nine in a ten-inch pot. The compost used was good loam, spent mushroom bed manure, and some old mortar rubble and sand. Efficient drainage was provided, and care taken not to give too much water while the plants were taking possession of the new soil. Greenhouse treatment and a light position followed potting, and a sunny frame sufficed during the height of summer. Under these conditions flower spikes developed in August, and the flowers were at their best at the beginning of September. As each flower faded it was removed, but the spike was never cut, being allowed to die down. Immediately the flowers began to fade the water supply was very much reduced, and the plants induced to rest, but severe drying off so as to cause all the leaves to die was not practised. The vallota loves sunshine and fresh air, and it appreciates a few doses of weak liquid manure when well established, especially the second season after potting.

DISEASED PEAR GROWTHS.—A. W., Hyde Park: I am sending herewith a few shoots of my Winter Nelis pear tree, and shall be much obliged if you will kindly tell me the cause of its malady. Wherever the tree is pruned it invariably dies back a considerable distance from the cut portion. I have also a Sturmer Pippin apple, which also resents being cut back. My garden is close to the sea, at Milford-on-Sea, Hants, where we grow all kinds of fruits, including pine-apples, oranges, etc. I have a great many varieties of apples and pears, and usually our cultivation is successful. Any information you can give to one who has been a subscriber to The Gardeners' Magazine for fifty years will be greatly appreciated.—The shoots sent are badly attacked by canker, and were evidently predisposed to attack by reason of their green and sappy condition. Judicious pruning should be at once carried out, removing all badly infected branches and painting the wounds with Stockholm tar. If

there are wounds on older branches pare them down to clean, healthy wood and bark, and paint with Stockholm tar. When cutting back the infected shoots, do so a good distance behind the nearest infected part, because the mycelium travels in the tissues, and so may not be entirely eradicated. It is probably because the previously damaged shoots were not cut back sufficiently to remove the whole of the diseased portion that the canker has spread. Promptly burn all the shoots and branches removed. Allow the diseased trees to crop very lightly; watch for and promptly deal with any further outbreaks, and next winter spray the trees thoroughly with a sulphate of iron solution.

MINT RUST.—C. R. D., Cheam: I enclose a few pieces of mint taken from a narrow bed growing in warm, moist position near a garden wall. The stems are distorted, and of a yellowish colour. Kindly tell me what the disease is, and how to remedy it.—The mint is suffering from an attack of mint rust (Puccinia menthæ), and as the whole cycle of the life of this fungus takes place on the mint prompt measures should be taken to eradicate the disease. The mycelium is perennial in the underground stems, hence it is necessary to entirely remove and burn all infected plants, carefully digging them up so that no portion is left in the ground to continue the disease. Propagate a new stock from stem cuttings made from clean, healthy plants, and make a new plantation quite away from the old one. Old beds, where the plants have become matted together, and more or less starved, seem most liable to infestation.

THE MOONLIGHT BROOM.—S. J., Warminster: I had a plant of the Moonlight Broom given me last season, and, as advised, planted it upon a rather dry rocky bank. It was a very straggling specimen, and looks even more ungainly now, therefore I should like to know how to deal with it so as to bring it into a better shape. By the way, what is the correct name of the Moonlight Broom?—The Moonlight Broom, Cytisus praecox pallidus, is a charming flowering shrub, and yours is planted in a most suitable position, as the plant loves sunshine and a moderately dry rooting medium. Directly after it has flowered cut the growth hard back, and this will induce shapeliness, many growths, and greater freedom of bloom the next season.

FLOWERS FOR A BLUE BORDER.—N. H. K., Lincoln: Will you kindly indicate a few of the best plants for use in the preparation of a blue border, as I am anxious not to omit anything of importance.—Anchusa italica in variety, with violas, lavender, aquilegias, annual and perennial asters, eryngiums, echinops, geraniums, campanulas, dracocephalums, galegas, gentians, Lithospermums, scabiosas, verbenas, delphiniums, erigerons, iris, polemoniums, mertensias, aubrietias, muscaris, scillas, linums, anemophalodes, aconitums, ajuga, anemones, clematis, lupins, myosotis, and salvias, are all families that include blue-coloured flowers which should find a place in a blue border.

NAMES OF PLANTS.

A. C. B., Handsworth.—1, Odontoglossum cirrhosum; 2, O. Adrianæ.

O. W., Shepperton.—1, Berberis Hookeriana; 2, Prunus serrulata fl. pl.

S. N. A., Abingdon.—1, Rhododendron racemosum; 2, Berberis stenophylla; 3, Primula rosea; 4, Morisia hypogæa.

E. N., Grays.—1, Retinospora obtusa pendula; 2, Pinus Laricio; 3, Cupressus macrocarpa; 4, Phyllostachys viridi glaucescens; 5, Cupressus Lawsoniana variety.

J. S., Alverston.—1, Cupressus torulosa (probably); 2, Juniperus chinensis albo variegata; 3 and 4, send more characteristic specimens; 5, Pittosporum undulatum; 6, send when in flower; 7, a species of Kleinia; 8, Pulmonaria officinalis; 9, Anthericum variegatum; 10, Staphylea colchica; 11, Streptosolen Jamesoni. You have greatly exceeded the rule which limits specimens sent for naming to six.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

TUESDAY, April 29.—Royal Horticultural Society; Narcissus and Tulip Committee meets at 11.30 a.m.; Fruit, Floral, and Orchid Committees at 12 o'clock; Lecture at 3 p.m. on "Spring Border Plants," by Mr. George Bunyard, V.M.H.; Scientific Committee at 4 o'clock.

National Auricula and Primula Society's Exhibition at Royal Horticultural Hall.

WEDNESDAY, April 30.—National Auricula and Primula Society's Midland Show at the Botanic Gardens, Edgbaston; two days.

The following dates of exhibitions have been recently announced:

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.

Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.

Ealing Horticultural Society, July 9.

Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.

Ulverston Rose and Sweet Pea Show, July 18.

Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.

Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.

Tunbridge Wells Flower Show, July 23 and 24.

St. Quintin Horticultural Society, July 24, in the Gun Club grounds, Wood Lane, W.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Lessons from the Ghent Quinquennial.

As the comprehensive report which we publish in our present issue so clearly shows, the great horticultural exhibition that has been held at Ghent during the past week has fully maintained the traditions of this famous old Flemish city as one of the great centres of commercial horticulture, not only of Belgium, but of Europe. Ample evidence is also afforded that the whole of the multiferous details were carried out with a degree of completeness and success as to reflect the highest honour upon those who were responsible for the management of this great and highly important undertaking. Not one of the many members of the international jury with whom we had the pleasure of conversing when we were at Ghent expressed himself as otherwise than profoundly impressed by the completeness of the success that had been achieved; and some of the British horticulturists who on this occasion made their first visit to the Ghent Quinquennial, stated that they were amazed by the wondrously beautiful colour effects that met their eye on entering the great hall, and delighted by the charming combinations of flowers and foliage that attracted their attention in the course of their tour of inspection. It is pleasant to bestow praise when so thoroughly deserved as was the case at Ghent; but our object is not to indulge in commendatory platitudes, but to briefly refer to a few of the object-lessons that this great gathering afforded. One of the first of these lessons was a sense of failure on the part of past horticulturists in not giving attention to the question of providing within the metropolitan area a building with some ground attached that is really suitable for flower shows. It was very generally thought when the Horticultural Hall was built, and not without justification, that it would suffice for all but the largest gathering; but so great has been the advance in gardening since then that it hardly suffices for the fortnightly shows. The question is a difficult one, if not practically impossible of solution, for the acquisition of land in a really convenient position of sufficient size to accommodate an exhibition hall with an area of seven or eight acres will hardly admit of profitable discussion at the present time. What might have been accomplished at some distant period is, of course, problematic; but we are taught by one of the lessons of the Ghent Quinquennial, that by the exercise of foresight and enterprise, and the united effort of all concerned, the society has had for a long time a suitable position wherein to hold the quinquennial gatherings that have had so beneficent an influence on the prosperity of the nursery trade of Belginm. Another lesson of great practical value is that on the importance of so arranging an exhibition that the plants, flowers, etc., form a harmonius whole, instead of bting, as is so often the case a certain number of units, which may or may not be related to each other. In the two halls the arrangements were such as to suggest two delightful gardens, one furnished with greenhouse and hardy plants, and the other with plants from tropical and sub-tropical regions. These were not simply grouped on the grass without reference to their environment, but the contributions from the several exhibitors were so arranged that, while representing the individuality of the exhibitors, they constituted as it were a charming picture. The groundwork was green turf, intersected with broad, gracefully curving walks, and on the turf were beds of various shapes, and, in suitable positions, mounds and raised borders, and in the eastern and western annexes of the great hall the ground was slightly undulated. The walks were formed with a dull-coloured sand that was pleasant to walk upon and agreeable to the eye, as the colour did not, as in the case of bright gravels, clash with the colours of the flowers near the walks. Thus it was that in passing through the exhibition the visitor had constantly spread out before him a flower garden of great beauty, while the interest was constantly maintained by meeting at frequent intervals with plants differing more or less in colour or character. Another object-lesson to which many of those who are concerned with horticultural exhibitions in this country should give their attention is the regulation of the top light. At Ghent it has long been the rule, whether the structure be of a permanent or temporary character, to have a certain amount of glass in the roof, and subdue the light by means of thin canvas suspended from the roof. As we enjoyed the soft light produced by the canvas suspended cloud-like overhead, we were reminded of the great difference in the attractiveness of plants and flowers exposed, as at Olympia in 1911, to the direct effects of brilliant sunlight, and of the improvement that would have been made in the appearance of the big tent at Chelsea on the occasion of the International

FIELD-MARSHAL THE RIGHT HON. LORD GRENFELL, G.C.B., F.S.A., LL.D.,
President of the Royal Horticultural Society.

Horticultural Exhibition last year, had thin canvas been so employed as to hide the framework of the roof. To the quality of the plants, flowers, fruits, and vegetables seen at our exhibitions there is no occasion to refer, for it is generally acknowledged, both at home and abroad, that British cultivators have no superiors. It is probably due to this fact that the various authorities have become somewhat lax in the conditions under which exhibitions are held. Not improbably it is thought that the high state of development of the various products is sufficient to attract and satisfy visitors. To a certain extent this may be the case, but it does not in any way relieve the wealthy societies of their responsibility of providing the means whereby the products of the garden can be presented to public notice in the best possible manner. We are anticipating with much interest whether any reforms in methods of exhibiting will be made by the Royal Horticultural Society at Chelsea, as compared with the shows held in the gardens of the Inner Temple, where, owing to the limited space, a satisfactory method of procedure was impossible.

Field-Marshal Lord Grenfell, G.C.B., G.C.M.G., LL.D., who has succeeded Sir Trevor Lawrence, Bart., as president of the Royal Horticultural Society, and whose portrait we have the pleasure of giving herewith, may not be a horticulturist as that term is usually understood, but he is keenly interested in gardening; and, as evidenced by his brilliant military career, possesses administrative ability of an exceptionally high order. Entering the Army in 1869, Lord Grenfell served in the Kaffir and Zulu wars some ten years later. Between 1882 and 1892 he was engaged in the several Egyptian expeditions, and was Sirdar of the Egyptian Army from 1885 to 1892. Subsequently Lord Grenfell occupied at different periods the positions of Inspector-General of the Auxiliary Forces, Governor and Commander-in-Chief of Malta, and commanded the Egyptian Army, the 4th Army Corps and the Forces in Ireland. In recognition of his service Lord Grenfell was raised to the peerage as Grenfell, 1st Baron of Kilvey, in 1902.

Bluebells at Kew.—The Royal Gardens, Kew, are peculiarly attractive at this season of the year, when the beeches, limes, and bush chestnuts are breaking out into fresh green leafage, and when the grass possesses rich greenness not seen again through the year. There are early-flowering shrubs in abundance, and alpine flowers in great variety and beauty. Tulips provide rare masses of glowing colour, while wallflowers and polyanthuses yield sweet fragrance. But away beyond the cultured portions of the gardens, in that wonderful bird paradise, the Queen's Cottage grounds, the bluebells are fine, and well worth a visit, as the many acres of these lovely flowers possess that charm which attaches to all things beautiful in a state of nature.

Trial of Spraying Machines at Wisley.—A practical demonstration of spraying machines and syringes was held, under the auspices of the Royal Horticultural Society, at the Wisley Gardens, on Wednesday, April 23. A large number of machines and a great variety of nozzles and attachments were brought forward by well-known makers, including Messrs. G. and W. Purser, Messrs. Hartjen and Co., the Four Oaks Spraying Machine Co., Messrs. Robinson Bros., Ltd., the Boundary Chemical Co., Messrs. E. A. White, Ltd., Messrs. Cooper, Pegler, and Co., Messrs. Benton and Stone, and Messrs. Cooper and Nephew. We shall publish a full, illustrated report of the trials in our issue for May 17, when we shall specially deal with insect pests of trees, plants, and vegetables that engage the attention of cultivators at this season of the year.

History of Orchid Culture.—In our next issue we shall publish a freely illustrated article dealing with the historical aspects of orchid culture in Great Britain. Written in a popular style the article will place the reader in possession of the more important facts relating to the early introduction of orchids into this country, the difficulties experienced by the earlier cultivators, the introduction of species, hybridisation of orchids; and it will contain a reference to some of the chief cultivators and raisers and their work.

Gift of Roses to the Queen.—The Royal Society of St. George presented the Queen with a beautiful gift of English roses, arranged to represent a ship, on St. George's Day. Her Majesty was much pleased with this floral offering, its design, and its commemorative interest.

Tree Planting for Profit.—On the 18th inst., Mr. Augustine Henry, V.M.H., who has recently been appointed Professor of Forestry at the Dublin University, lectured at Carpenters' Hall, London, on "The Choice of Trees for Profitable Planting. In the course of his lecture he stated that in making a selection the planter must be guided by the suitability of the trees to soil and climate, quick returns from rapid growth, and increasing value of timber. Native trees were not always best for these purposes. Trees introduced from similar climates of the Pacific Coast of North America or the Corsican Highlands had proved most profitable. Among the conifers recommended were the Corsican pine, the Douglas fir, the Sitka spruce, and the Pinaster pine. Of the broad-leaf trees the Spanish chestnut, the so-called Italian poplar, and the ash gave the best returns. Sir Herbert Maxwell, F.R.S., who presided, said the large audience proved the growing interest in the neglected study of Forestry. He was glad to see so large a gathering, for the subject was of great national importance, because the demand for timber in our various industries was constantly increasing, while our sources of supply were being rapidly exhausted.

Mr. J. F. McLeod, who has been head gardener and bailiff at Dover House, Roehampton, since 1889, has been left an annuity of £250 by his employer, the late Mr. J. Pierpont Morgan, who left legacies to many of his employees in England and America. We are glad to learn that Mr. McLeod's services have been so signally and handsomely acknowledged.

Buoyancy of Seeds.—Mr. Lloyd Praeger contributed to the recent meeting of the Royal Dublin Society an interesting communication on the buoyancy of the seeds of some British plants. At the outset of his communication Mr. Praeger referred to the fact that the importance of the question of the buoyancy of seeds in water in connection with the dispersal and distribution of plants has been long recognised. The experiments of Darwin, Martins, Thuret, and Guppy lead to the generalisation that only about one-tenth of a flora bear seeds capable of more than a very brief period of buoyancy. The present experiments were undertaken in order to furnish further data for a study of the dispersal of our native species. Hitherto results were available for about 330 native species, but the number of species tested is now raised to 900. The results bear out the conclusion already mentioned; also Guppy's conclusion that the buoyant seeds belong mainly to maritime and marsh species. Some results relating to fresh and dried fleshy fruits and also to fruiting branches were given.

Origin and History of Garden Vegetables.—Those who have had the pleasure of hearing the Rev. Prof. E. Henslow, V.M.H., lecture upon the origin of our popular vegetables, will be glad to learn that the Royal Horticultural Society has now issued a reprint of the professor's lectures in booklet form, at 2s. There are 71 pages of matter, many reproductions from old illustrations of vegetables, and an excellent index. The title of this interesting and valuable reprint is "The Origin and History of our Garden Vegetables, to which is added their Dietetic Values."

Research Scholarships in Agricultural Science.—The Board of Agriculture propose to award in October next 12 research scholarships in Agricultural Science, of the annual value of £150, and tenable for three years. These scholarships have been established in order to train promising students under suitable supervision, with a view to their contributing to the development of agriculture, either by carrying out independent research or by acting in an advisory capacity to agriculturists. They will be granted only to students who show distinct promise of capacity for advanced study and research in some one of the sciences bearing on agriculture. Applicants must be graduates of a university or holders of a diploma of a university or college of university rank, and application should be made not later than June 9 next on a form to be obtained from the Secretary, Board of Agriculture, Whitehall Place, London, S.W.

Lime-sulphur Wash and Potato Disease.—In the summer of 1912 experiments were conducted at the New York Agricultural Experiment Station for the purpose of testing the relative merits of lime-sulphur wash and Bordeaux mixture as a preventive of potato disease. It was found in the trials that while the Bordeaux mixture greatly reduced the percentage of diseased tubers, and increased the bulk of the crop, the lime-sulphur wash had comparatively little effect as a preventive of disease, and reduced the yield, as compared with the unsprayed plots. The wash is described as having scorched the tips of the leaves, and caused them to die off prematurely.

Eradication of Meadow Saffron.—Two implements have recently been described in the German journals which have been designed for the eradication of the Meadow Saffron, Colchicum autumnale, from meadows. One of these consists of a digging iron, to which pieces of iron or steel are fixed cross-wise with the lower edges sharpened for cutting. In use the implement is driven into the ground over the colchicum, and the corm is cut to pieces and the portions quickly decay. The other implement is a short, three-pronged iron, moving on a hinge, and fixed at the end of a digging iron, resembling a crowbar, with the lower part somewhat flattened. On the implement being driven into the ground, the prongs close in an upward direction, but, on turning it round in the ground, so that the prongs are underneath the corm and in pulling it up the prongs open and grasp the corm from below, so that it can be pulled out of the ground. So far it has not been found possible to clear the ground in a shorter period than two or three years. It is, therefore, of some importance to know that in a similar period the colchicum can be eradicated by the use of a heavily-weighted bush-harrow. This implement is

...over the ground twice in the autumn ... an interval of two or three days, and ... observing the flowers the following ... seeding is prevented. The meadow ... is a poisonous plant, and therefore ... should not be allowed in meadows ... which it is growing.

Colour in Flowers.—In the course ... highly interesting lecture given before ... members of the Royal Institution, Dr. ... Frankland Armstrong stated that the ... extracted by alcohol could be ... as a separate deposit, and the ... petals still be able under certain ... to assume fresh colour-adornment. The present hypothesis was that ... colourless substance, chromogen, was ... into pigment by oxidation. This ... easily brought about in the plant cells ... means of oxydases. The two factors, ... and oxydase, were necessary to ... production of colour, and if either was ... there was no colour. Considerable ... had been made in unravelling the ... presented by colour, which ... two types—the plasteid pigments, ... in water, generally yellow or red, ... the carrot or tomato, and the soluble ... anthocyanin pigments, red, rose, ... blue, and other shades of which ... garden flowers afforded examples. A ... might be coloured by either type or ... both.

Afforestation in the Black Country.—The Midland Re-afforesting Association continues its excellent work of planting timber trees upon the ugly pit-mounds and slag-heaps of South Staffordshire. The annual meeting was held at the University Buildings, Birmingham, this week, and Sir Oliver Lodge, who presided, stated that a grant of £100 had been promised from the Development Fund for the ensuing year, and so their work was receiving Government recognition. A scheme of experimental planting is to be drawn up and presented to the Board of Agriculture. The actual area the Midland Society would like to see planted is 14,000 acres, but the work is severely limited by lack of funds.

Wages of Kew Gardeners.—The claims of the working gardeners at Kew for higher wages are stated in a leaflet by Mr. William Purdom, secretary of the Kew Gardens Employees' Union. It is said that about fifty gardeners are employed at a wage of 21s. per week, while the labourers employed receive 23s. and 24s. Both classes of employees work from 6 a.m. to 6 p.m. in summer, and from daylight till dusk in winter; while the labourers have a half-holiday every Saturday, the gardeners only receive this every other week. It is also pointed out that, while the gardeners at Kew have a wage of 21s. per week, those working in the Royal parks receive 27s., and gardeners in the parks under the London County Council receive from 27s. to 30s. The official reason for this difference is that the gardeners at Kew enter the Royal Gardens, Kew, for the improvement of their knowledge of the scientific and practical aspects of horticulture, and, with reference to this, Mr. Purdom says: "The gardeners enter the service at Kew as skilled workmen, and are treated as such throughout their stay, with the exception that they are not paid even at the rate of unskilled workmen."

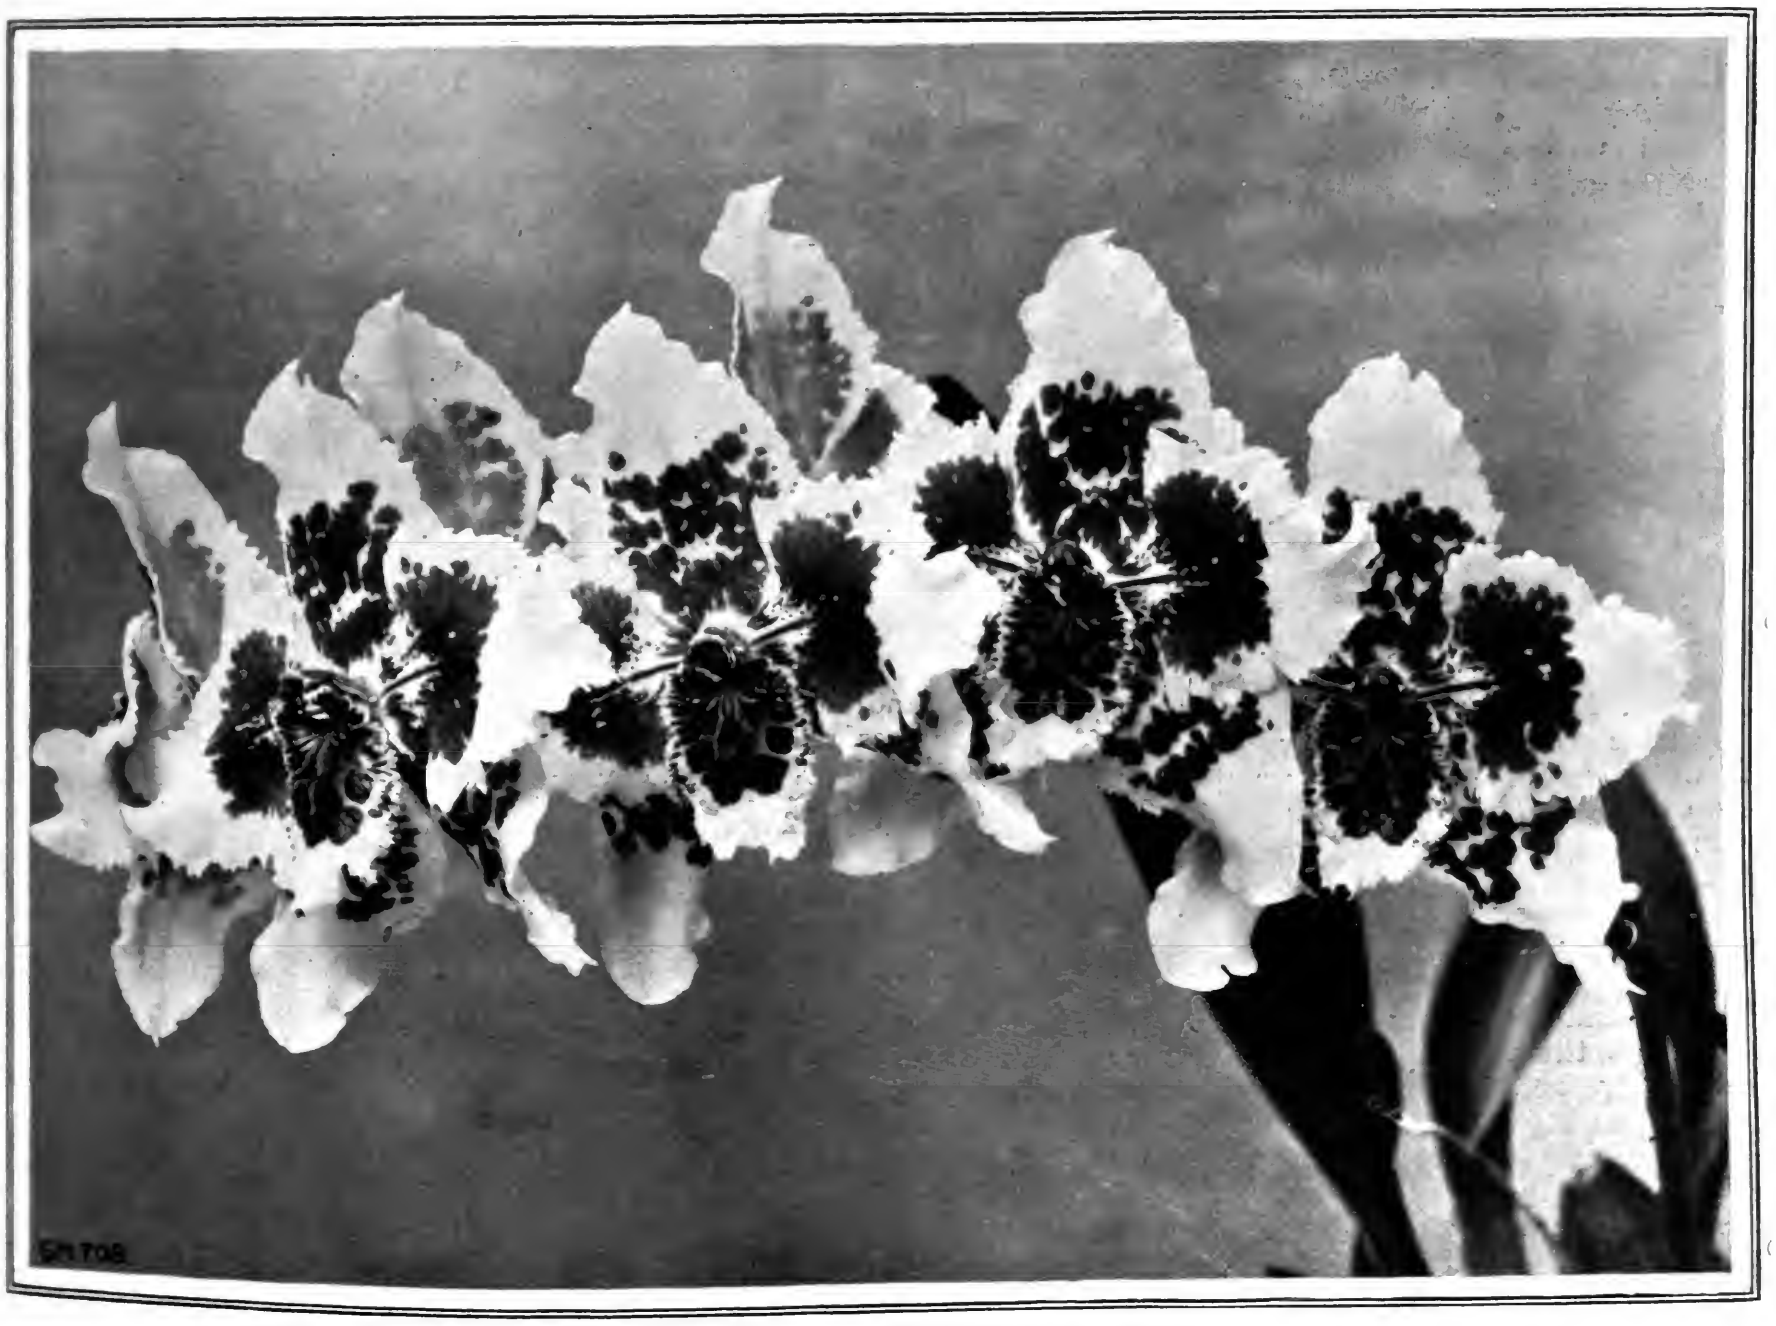
Tobacco Culture.—According to a statement recently made by Mr. Runciman one hundred and twenty-eight acres have been approved by the Customs for the cultivation of tobacco in Great Britain.

FEIJOA SELLOWIANA.

A dozen years or more ago attention was directed to this myrtaceous shrub as a promising fruit for the warmer regions of the globe. It was first introduced by the late M. E. André in 1890, but it was some years after before it was generally distributed. It is a native of Southern Brazil and Uruguay, where it is said to attain the dimensions of a large shrub or small tree. From a botanical standpoint it is very nearly related to the guava, and the fruit is reported to be equally delicious. I am not, however, aware if it has fruited in this country, or, even if it has, whether the fruits are such as to merit the praise which has been bestowed upon them. From a decorative point of view, however, this Feijoa is well worth growing, for when in bloom it is decidedly striking. A specimen is trained up the end of the Economic House at Kew.

As it is but little known, a brief description of this Feijoa may be useful. It forms a freely-branched shrub, whose rather slender shoots are clothed with oblong-shaped leaves, three to four inches in length, and of a deep green tint. The flowers, which are borne in small clusters, are individually, when fully expanded, about a couple of inches across, and composed of four fleshy petals of a curious hooded shape. These petals are purplish inside, and almost white on the exterior; but, owing to their hooded shape, set up by the incurving of the edges, the outside with its paler tint is exposed. As with other members of the myrtle family, the long, slender, bright red filaments, with yellow anthers disposed in a brush-like cluster in the centre of the flower, form a very conspicuous feature of the inflorescence.

K.



ODONTOGLOSSUM AMABILE VAR. ZEUS.

Flowers pure white, with rich rosy-crimson markings. A.M., R.H.S., April 29. Lieut.-Colonel Sir George Holford (gardener, Mr. H. Alexander), Westonbirt, Tetbury.

MAY-TIME AMONG THE ROSES.

With an early Whitsuntide some ardent rosarians may, perhaps, have more time at their disposal than usual, and a few notes may be welcome. At all seasons there is quite a lot of important work to be done in the rose garden during this month, when all life is abounding.

In mid-Sussex we have apparently been much more fortunate than in the Midlands and North, from which places I am receiving quite a shoal of letters bemoaning the almost entire loss of our generally hardy Wichuraianas and Ramblers. My own have not completely lost their leaves, and in many cases have not had their soft points checked, except in a few exposed situations. At the time of writing these are carrying long, young growths, springing from the best and partially-ripened eyes on last year's rods. It seems rather strange, that, although these and a few others in sheltered places are so forward here, we are by no means earlier than usual with our hybrid perpetuals, teas, and hybrid teas, in the more exposed beds. At present I look for a good season, seeing we have the first and important essential of well-ripened and frostless wood except among these few precocious growers.

The disbudding of rose growths, noted in April, should be very general now, for one should be able to decide before so many of our early and mid-June varieties open. The early battle against insects and mildew may also be urged, for we cannot well do worse than allow these enemies to get a firm holding.

Should warmer weather set in, there will be considerable progress in the growth of maiden roses, budded last summer. On looking over our own I am quite satisfied by the way they have come through the winter, so far; but fear our northern friends can scarcely say the same, according to their reports of what should have been sound and hardy growth. By the end of the month our dwarf maidens will need careful suckering, the soil cleaned and loosened around them, some soft and suitable mulch used, and the surrounding soil drawn up towards the young roses. Our own rows strongly resemble earthed-up potatoes, and when this is done carefully there is a considerable support afforded to the young plants. They are not only sheltered a bit, but helped against wind, while at the same time earthing assists a junction of rose and stock. But wait until the bud has moved, and do not actually cover it.

If you are forward not a few of these dwarfs will need heading to secure stout and bushy plants. In the case of a few varieties, grown in the maiden stage chiefly to procure good exhibition blooms, no heading will be needed. I allude to Horace Vernet, Louis Van Houtte, Alfred K. Williams, Baroness Rothschild, Comtesse de Ludre, Gloire de Chedane Guinoisseau, Gustave Piganeau, Ulster, and Xavier Olibo, from the hybrid perpetual section; while from the hybrid teas we may select Lady Mary Fitzwilliam, White Lady, Tennyson, G. C. Waud, Lyon Rose, Mrs. David McKee, Mrs. Theodore Roosevelt, Pharisaer, Queen of Spain, and William Shean, which have come better with me for that purpose when not headed at the first.

This reminds one of the need for some support to dwarf maidens, and whatever is used give a little thought to the average growth of each variety. Let your supports be of three distinct lengths, not using a five or six-feet sticks for a moderate grower of a little over eighteen inches, or a two and a-half feet one as support for an extra vigorous grower or climber. Some of the latter may need a stout stake standing six feet or more from the ground. The plants not only look vastly better, but enjoy more of the necessary light and air when staked with a little judgment.

The stems of standards will need attention, and suckers removed. One can manage a large quantity in a short time if the work is done while the shoots are young and soft.

Some of our wall roses may be very dry at the roots even thus early in the season, especially when planted close to cellars and basements. Water freely with weak liquid manure as most of them will be carrying nearly full growth, and be imposing a great strain upon the roots now.

ROSARIAN.

GROUPING ALPINE PLANTS.

There is much to recommend in the more natural massing of the plants that are employed to furnish rock gardens than that which at present obtains.

The charm and fascination of the alpine flora, as seen in its native habitats, is due, in great measure, to the widespreading drifts which present distinct aspects of vegetation, both as regards colouring and habit. This lends character and fine effect, and it is to be deplored that many rock gardens, the construction and planting of which has involved a big outlay, lack these essentials to real success.

Apart from the fact that many rare gems come to grief when called upon to enter into competition with species that have little to recommend them beyond a rampant habit of growth, the dotting of mixed plants over the whole surface spells mediocrity. It is of vital importance that the grouping be carried out in a free and natural manner, and he who is wise in his generation will inspect and gather inspiration from the splendid examples that exist at Kew and other large public gardens. In this way, backed up by personal taste, artistic perception, and an innate love for the subjects dealt with, formality will be conspicuous by its absence.

I am not quite sure as to whether the practice of planting coarse and sometimes irrelevant subjects in newly-formed rock gardens, with a view to hiding a good deal of its surface until the legitimate inmates have made their presence felt, is a good one. At any rate, it may be said with truth that where they are allowed to deprive the alpines of light and sunshine it is a huge mistake, and, to my mind, the better plan is to steer clear of obstacles, and to do everything possible to bring about a well-furnished rock garden without calling in the aid of temporary plants.

WALTER H. AGGETT.

Hovea Celsi.—In the days when hard-wooded plants were so universally grown this was regarded as a good test of the cultivator's skill, for very careful attention was needed in order to have it at its best. It is a native of Australia, and, like many other old-time favourites, belongs to the natural order Leguminosæ. It is of rather rambling habit, and needs to be pinched freely when young in order to lay the foundation of a bushy specimen. The leaves, which in shape are narrowish and ovate, are of a deep green colour, while the pea-shaped flowers, borne in clusters in the axils thereof, are of a beautiful deep blue. It is also known as Hovea elliptica.—K.

FRITILLARIA PERSICA.

The culture of the majority of the Fritillaries is by no means a simple matter, but the subject of this note has the merit of being one of the easiest to grow of the whole race, which is, as a rule, not especially adapted to ordinary border culture. The stately Crown Imperial (F. imperialis) is certainly, in common with F. persica, by no means exacting in its requirements, and grows vigorously in the herbaceous border, where its large, pendant bell-shaped flowers, clear yellow or orange-red in hue, give a welcome spot of colour in the early spring.

F. persica, though admittedly inferior to the Crown Imperial in brightness of colouring, is an interesting and attractive plant of graceful habit, but is seldom met with in gardens. Strong specimens throw up flower-stems over three feet six inches in height, the upper sixteen inches of which carry blossoms. As many as thirty blooms are sometimes carried on a single spike. The flowers are of shallow bell-shape, drooping, and nearly an inch in diameter. They are brownish-purple in hue, much the colour of a Black Hamburgh grape, and have a grape-like bloom. On reversing the flowers, the golden anthers are seen to contrast charmingly with the dark interior. The leaves are lanceolate and glaucous green in tint, the lower ones being six inches in length and one inch in breadth, diminishing in size as they ascend the stem.

This fritillary flourishes in heavy or in light soil, and in sunny as well as partially-shaded positions, while moisture, which is indispensable in the case of some species, is not necessary, since the plant may be seen making good growth and flowering well in dry borders. A bulb once planted generally makes good progress, the flower-spikes increasing in number and size as the years pass. The plant is of robust constitution, and is perfectly hardy in the southern counties. The plant is elegant in growth, and has a striking and unique personality, which renders it welcome in the border. It has this year bloomed fully three weeks earlier than its usual season.

WYNDHAM FITZHERBERT.

EPIPHYLLUM MAKOYANUM.

This is totally distinct from the well-known Epiphyllum truncatum, which is represented in our gardens by several varieties. While the growth of S. Makoyanum is a good deal after the manner of that of E. truncatum, it differs markedly in other respects, as the flowers are scarlet, and as regular in shape as a cactus, being thus totally unlike the oblique blooms of E. truncatum. Furthermore, this last flowers in the winter, while E. Makoyanum blooms in the spring, or even in early summer. There is a nearly allied kind, E. Gaertneri, which is a good deal like E. Makoyanum; indeed, the difference between the two is only apparent on close inspection.

Both these can be grafted on to the pereskia as readily as E. truncatum itself, and they succeed under just the same treatment. A method not often seen, but a very effective one with both these sections of epiphyllum, is to train a strong shoot of pereskia up the rafter or roof of a warm greenhouse on which the sun shines. When sufficient space is covered with the pereskia it is then grafted here and there with the epiphyllums, and as they grow and form tufts on the branches they have at all times a singular, and when in full bloom, a striking effect. S. W.

THE GREAT INTERNATIONAL HORTICULTURAL EXHIBITION AT GHENT.

VIEW IN THE GREAT EXHIBITION HALL, GHENT,
In which Azaleas, Carnations, and Rhododendrons were the chief features; the Carnations are shown on the right.

IN connection with the first great Universelle Exposition held at Ghent, Belgium, the Société Royale d'Agriculture et de Botanique de Gand held its seventeenth quinquennial horticultural exhibition from Saturday, April 26 to May 4. On previous occasions the exhibition has been in the Casino and a temporary building, but now a large new site has been obtained close to the Exposition Générale, and upon it a superb new central hall, covering over four acres, with annexes and salle extending the covered area to over seven acres, has been built, and a magnificent building will remain as a souvenir of the greater exhibition. Would that we horticulturists had such a hall in London for flower shows. At present the Royal Horticultural Hall is admittedly all too small for the majority of exhibitions, and the Crystal Palace is also too far from the City of London for most people.

Let us say at once that the exhibition was not so varied in character as our own International, but far more effective, because under the care of M. Bervenich, it was disposed as a great, well-balanced garden, with long beds, borders, banks, and winding paths, while the painted scenery in several parts of the great hall carried on the area apparently to an immense distance. The paths were not, as is usually the case in this country, formed with a strong yellow gravel that clashes with many of the flowers exhibited, but with sand of very subdued colouring with a faint tint of green. This sand was pleasant to walk upon and restful to the eye, and in general appearance suggested a walk through a woodland glade on which moss had begun to make its appearance.

The main building was devoted to azaleas and other subjects that either thrive in the temperature of a greenhouse or conservatory, or are quite hardy; the orchids found a home in the series of large salons; and the stove plants, remarkable for the beauty of their flowers or foliage, were arranged in the large salle on the north side of the main building. This structure was heated with a well-arranged system of hot-water pipes, which were placed in grating-covered tunnels along the middle of the principal walks, and maintained a temperature sufficient for the plants, and not so high as to be unpleasant to the visitors. As is customary at the horticultural exhibitions held in this old Flemish city, Indian azaleas were shown in immense numbers, and in all sizes, ranging from small plants with heads twelve inches or so in diameter, to huge specimens six or more feet in diameter. The immense space given to these greenhouse shrubs is explained by the fact they form one of the great features, if not the greatest feature, of the nursery trade of the district of which Ghent is the centre. Arranged with more or less taste in the great hall, the display of colour was such as to suggest a vast azalea garden of dazzling splendour. The colour effect was almost too brilliant, notwithstanding the skill with which the light had been subdued by the thin canvas cleverly suspended from the roof. Therefore, as the eye ranged over the vast masses of colour, one could have wished that a few tall palms, with wide-spreading leaves or tree ferns of large size, had been arranged at suitable intervals on the floor of the building to form a relief to the great areas of brilliantly coloured flowers.

JUDGING.

An exhibition that includes 841 classes, besides non-competitive displays of great size and merit, needs a small army of judges to make certain that the prizes are awarded promptly. Judging commenced on Friday, April 25, the jury assembling at 8.30 a.m., when they were welcomed by M. Callier, the president. At the roll call every member of the jury received a packet

containing a schedule, a pocket-book and pencil, cards of admission to certain social functions, a red note to be exchanged next day for a complete catalogue of classes, exhibitors, jurors, and prize-winners, and a neat little silver-gilt medal-like souvenir, which, pinned on the coat, secured for its wearer free entrance to the exhibition, and, incidentally, the salutes of every gendarme and official.

About three hundred and fifty jurors, gathered from Belgium, England, Ireland, Scotland, France, Germany, Italy, Switzerland Austria, Denmark, Egypt, Spain, Holland, Luxembourg, Russia, and Sweden were grouped into forty-nine sections, each with its own president, secretary, and two commisaires; indeed, everything was done to expedite the work, and secure the publication of the awards at the earliest moment.

The Britishers who answered to the roll call were Sir Harry J. Veitch, "President d'Honneur General"; Messrs. J. S. Brunton and R. Ker, vice-presidents; Sir F. Moore, Sir Jeremiah Colman, and Messrs. H. Alexander, Jas. Backhouse, C. H. Curtis, W. Cutbush, R. Cuthbert, W. Cuthbertson, C. Englemann, R. Findlay, George Gordon, V.M.H., J. J. Guttridge, John Heal, V.M.H., James Hudson, V.M.H., Stuart Low, F. Menteith Ogilvie, J. S. Moss, Jas. O'Brien, W. H. Page, George Paul, V.M.H., C. Harman Payne, Chas. E. Pearson, R. Hooper Pearson, H. T. Pitt, A. R. Rolfe, H. F. C. Sander, C. H. Taudevin, Arthur Turner, P. C. Veitch, W. Watson, Jas. Whitton, J. Weathers, and J. Gurney Wilson.

SOCIAL FUNCTIONS.

The Ghent Society fully recognises the value of social functions. There was luncheon to the jury in the Casino on Friday, a Raont at the Bourse du Commerce on Sunday morning, and the dinner to the jury and officers at the Casino on Sunday evening, all of which were agreeable functions, and enabled horticulturists of many nationalities to meet and renew friendships. M. Callier, the president of the society, and M. Jules de Cock, the indefatigable secretary, were ever ready to render assistance.

As there were an unusual number of Britishers present on this occasion, it was suggested on the Friday that there should be a British gathering at the Hotel de la Poste on Saturday evening, so Sir Frederick Moore and Mr. R. H. Pearson arranged matters, and Sir Harry J. Veitch, V.M.H., President-General of the Jury, occupied the chair. Those present were: Sir Harry Veitch, Sir Jeremiah Colman, Sir F. W. Moore, Messrs. W. Watson (Kew), W. Cuthbertson (Edinburgh), J. Whitton (Glasgow), Professor Newstead and Professor Stevens (Liverpool), C. Harman Payne (Catford), W. Pettigrew (Cardiff), J. Guttridge (Liverpool), R. H. Pearson ("Gardeners' Chronicle"), Stuart Low (Enfield), P. C. Veitch (Exeter), H. Alexander (Westonbirt), R. Cuthbert (Southgate), George Gordon and C. H. Curtis (Gardeners' Magazine), W. Cutbush and L. Cutbush (Highgate), J. Weathers (Isleworth), F. Sander, Fritz Sander, and Louis Sander (St. Albans), Jas. Hudson (Gunnersbury), C. E. Pearson (Lowdham), J. S. Brunton (Burnley), W. H. Page (Hampton), John Heal (Chelsea), R. Ker (Liverpool), G. Wolfe (Bathgate), George Paul (Cheshunt), J. Collier (Reigate), C. Taudevin (Cheltenham), A. Findlay (Glasgow), J. Frogbrooke (Leyton), T. Bevan (Finchley), S. Brooks (Finchley), A. F. Dutton (Iver), C. Englemann (Saffron Walden), Arthur Turner (Slough), H. T. Pitt (Stamford Hill), J. S. Moss (Bishop's Waltham), J. Willis (Harpenden), Cairns (Glasgow), and J. McKercher (Highgate).

The toasts of "His Majesty King George," and "Their Majesties the King and Queen of the Belgians" were duly honoured at this gathering, and then Sir Harry Veitch gave "Continued Prosperity to the Ghent Quinquennial Exhibitions," and, in doing so, said that it was 51 years ago since he first came to a Belgian exhibition. Since then he had seen great changes in the style of the show and in its personnel. He referred to the several outstanding features, and especially to the "Yellow Pæony." Sir Jeremiah Colman proposed "Horticulture" in very happy fashion, and alluded to the growing taste for plants and flowers. Sir Frederick Moore gave "The British Jurors," and made a very hearty and breezy speech, in which he referred to the pride all felt that Sir Harry Veitch had been appointed President-General of the Jury. Britishers had turned out well on this occasion, and had not only come over themselves, but exhibited orchids and carnations in grand style to uphold and advance British horticulture. Mr. W. Cuthbertson and Mr. Pettigrew replied, and each said that some things in connection with a great exhibition were done better on the Continent than at home, and it was as well to take note of them. Mr. Cuthbertson emphasised the difference between the judging arrangements of Chelsea in 1912 and of Ghent in 1913, to the detriment of the former. Mr. George Paul very happily gave "Our Chairman," and feelingly alluded to their friendship of over sixty years, commencing with the days when both were at school together in Germany, and to the high position Sir Harry holds in the world of horticulture, and to his great kindness to all in need of help. Needless to say, this toast was received with great enthusiasm, cheers and musical honours. "Auld Lang Syne" concluded these unique proceedings.

Curiously enough, the Dutch growers dined together the same evening at the same hotel.

ORCHIDS.

Never before have orchids been so nobly exhibited at Ghent as on this occasion. Several salons downstairs and a series of handsome salons upstairs were filled with the choicest of these choice plants, making together a galaxy of elegance, glowing colour, chaste beauty and grace that merited and received the commendation of everyone who saw it. At previous quinquennial exhibitions there have been several small orchid exhibits of rather poor quality, and these detracted from the general effect, but this time every display was good; some were of extra merit, and a few were super-excellent. Our Belgian friends scored heavily, the leading amateur and trade growers showing their very best plants, splendidly grown and in fine style. The outstanding features were the glorious Miltonias from M. Jules Hye de Crom, the grand general exhibit from M. Firmin Lambeau, the odontiodas from M. Vuylsteke, M. Pauwels' cymbidiums, and Messrs. Charlesworth and Co.'s exhibit.

Just as Sir George Holford's collection was the great feature of the 1908 exhibition at Ghent, so on this ocasion the glorious and magnificent contribution made by Mons. Firmin Lambeau, Brussels, was the outstanding feature among the orchids. M. Lambeau secured the king of the Belgian's prize for the finest orchid display, and the award was well deserved, as it filled a very large salon and the hybrids and varieties were of the highest excellence, but if we offer a word of criticism it is only that the arrangement of the larger group was a trifle flat. When we being to discuss individual plants of great merit, the difficulty of ever stopping at once commences, and visions of a big catalogue of rarities rises in the mind's eye. However, we must make note of Brasso-cattleya Vilmoriana, the yellow B.-c. Leemannæ, B.-c. Ministre Helleputte, B.-c. Princess Elizabeth var. Madame Lambeau, and the delicate blush-tinted B.-c. Langleyensis, with four glorious flowers. Then, too, there were the golden L.-c. Lucia, and the exquisite golden-salmon L.-c. Firmini var. Ville de Gand, Cattleya Dusseldorfi var. Undine with a half-dozen pure white blooms, Phaius Norman, Odontioda Vuylsteke, O. Charlesworthi, O. Vesuvius of brilliant hue, and the wonderful O. Coronation, carrying fifteen magnificent scarlet, rose and yellow flowers. Besides all these there were literally hosts of high-class hybrid odontoglossums, fine forms of Cattleya Trianæ, and C. Schroderæ, and C. Mendeli, the bright Rananthera Imschootiana, and golden panicles of oncidiums with long, graceful spikes of Cymbidium Pauwelsi, C. Alexanderi, and the C. insigne from which these have been derived. Put in palms for a background, maidenhair fern for a ground work, a neat plaited wickerwork margin, and imagine the whole occupying a space about 60ft. by 8 or 10ft., and you have a faint idea of M. Lambeau's chief group; but he had three other groups in the same room, wherein the finest things were L.-c. Roi Albert, of L.-c. Dominiana style; Cœlogyne pandurata, a big cymbidium Humblotii, Eulophiella Elizabethæ with six spikes of dainty flowers, a long, graceful, and elegant Odontoglossum Phœbe, one of the finest of the O. cirrhosum crosses, and Odontoglossum Ville de Gand, a glorious hybrid with red, brown, and white colouring, and fringed petals.

Mons. Jules Hye de Crom, Ghent, came forward with a contribution of gorgeous orchids set in a large case; his varieties of Miltonia vexillaria were superb, but his odontiodas were equally fine, especially O. Vuylsteke, O. Bradshawiæ, O. Albert Hye de Crom, rich rosy crimson, Cattleya Schroderæ alba, var. Louis de Hemptinne, C. speciosissima alba The Empress, the long, white, yellow-lipped C. Suzanne Hye de Crom, and its var. eburnea, and Cymbidium Pauwelsi were all good. Exquisitely beautiful was Cattleya Schroderæ alba var. Louise Pauwels, a fine white form, while even finer, because so distinct, was Miltonia Madame Jules Hye de Crom, with large, solid, pure white blooms of most beautiful texture, with a purple flush at the base of each petal and a butterfly-like blotch of crimson-maroon at the base of the lip, with lines radiating into the whiteness of the larger area. This magnificent orchid had nine flowers, the largest nearly four inches deep, and three inches broad. Mons. and Madame Jules Hye had each a fine exhibit of miltonias, the forms of M. vexillaria showing a very fine range of colouring; with these were the beautiful M. Hyeana, M. Bleuana, and M. Bleuana nobilior; some specimens of M. vexillaria carried a dozen spikes, and every plant was perfectly grown. M. Hye de Crom was awarded many prizes, including a special work of art.

Mons. Charles Vuylsteke, Loochristy, Ghent, had a most attractive exhibit of seedling odontoglossums and odontiodas, carefully set over asparagus and moss in a huge glass case. We are not so startled now by M. Vuylsteke as a few years ago, but nevertheless he had some wonderful things on view, especially among the odontiodas. O. Blushing Bride had rounded flowers, white, heavily flushed with rosy blush, and with a heavy yellow crest on the white lip; O. Pierrot has the purest white ground flowers of good shape, the centre of each sepal and petal marked with very pale red-brown, this is most distinct, and adds to the range of colouring among odontiodas; O. Gloria Mundi would have set us all on fire had we not seen his splendid O. Coronation of a year or two ago; O. Gloria Mundi is crimson-scarlet on a blush ground, and the flowers are as large and finely-formed as those of a first-class odontoglossum. O. Proserpine is of the Bradshawiæ type; O. Brilliant has lovely, deep rose-coloured flowers; O. Vuylstekæ Roi des Belges has purple shading; while O. Vulcan has intense crimson colouring. Among the odontoglossums in this case the most striking were O. Saturnus, almost wholly coloured with deep blue-purple; O. Diamant, pure white; O. Queen Elizabeth, purple spotted over white; O. excellens Themis, large yellow; O. Armide, deep crimson-maroon, and O. Pomone, almost a blue odontoglossum.

M. Comte de Hemptinne, St. Denis, Westeren, Ghent, secured a gold medal for a delightful group of varieties of Odontoglossum crispum, every spike representing a fine form of this old species, but invariably the varieties were light-ground ones, heavily-blotched flowers being conspicuously absent. The Comte won a first prize for a Brasso-cattleya with B.-c. amabilis var. Madame T. Pauwels, with a gorgeous orange lip. He further secured a work of art for a group in which odontoglossums were conspicuously good and

cuvillias very showy. Brasso-cattleya Ingleton, a pure white hybrid between B. Digbyana and C. Trianæ alba was greatly admired and much commented upon. The Baron de Hemptinne's Cymbidium Lowianum, carrying five and twenty spikes, was an enormous specimen.

M. Maurice Verdonck, Chaussee de Brusegh, Goedbrugge, filled one salon with a brilliant assemblage of interesting orchids, and he had arranged his plants roughly in geographical sections. Many medals fell to his share. In the larger group his batch of Cymbidium Jamesianum was an attraction, and seldom is this white-flowered species seen in such good condition; Oncidium Marshallianum and O. splendidum, odontoglossums in great variety, cypripediums we have almost forgotten all about in these days of abundant hybrids; Dendrobium densiflorum with over a dozen spikes, Cœlogyne Massangeana with long drooping spikes; Phalænopsis Rimestadiana and Cattleya Schroderæ massed in great style, and a batch of varieties of Odontoglossum crispum were among M. Verdonck's chief successes.

De G. Ballion, a Ghent amateur, was awarded a gold medal for a delightfully-arranged group of oncidiums, odontoglossums, and odontiodas, with a fine Phalænopsis Schilleriana. Cymbidium Pauwelsi and the superb Brasso-cattleya Mariæ with huge purple-fringed flowers, and the new albino cypripedium memoria Alma Gevaert, derived from Maudiæ were a few of the most striking plants.

With a mirror to obtain effective reflections, and a high pyramid of Renanthera Imschootiana, mixed with Phalænopsis Rimestadiana and dark forms of Dendrobium Wardianum, M. Praet, Mont St. Amand, made up a showy exhibit. In the foreground Miltonias were associated with the golden Oncidium concolor, and there were splendid Brasso-cattleyas. Lælio-cattleya Hycana superba, and a four-spiked specimen of Miltonia vexillaria leucoglossa, with a fine example of Odontioda Vuylstekeana were among the finest plants in the centre of the display. M. Praet secured a work of art and a gold medal.

M. Charles Dietrich, Chateau Val Duchesse, Anderghem, had a most delightful group of orchids in the salons upstairs. It filled the width of a large room, and was composed chiefly of grand Brasso-cattleyas, cattleyas, and lælio-cattleyas. B.-c. Imperatrice de Russie with six flowers, B.-c. Vilmoriana with Mossiæ-like throat, B.-c. Maronæ, B.-c. Thorntoni, B.-c. Lehmanæ, and grand varieties of Cattleya Mendeli and C. Schröderæ were greatly in evidence, and produced a noble effect, to which the odontiodas and odontoglossums lent added grace. A work of art fell to M. Dietrich's share of the spoils. Lælio-cattleya Lucia inversa, one of the Charlesworthi breed, a strong grower carrying about half a dozen blooms on each 30in. spike, was well shown by Messrs. Vacherot and Lecoufle, Boissy, St. Leger; a score of plants were shown and there were three and twenty spikes. In some cases the sepals and petals were quite yellow, while in others they were salmon-buff, but the lip was ruby-purple all through.

A forest of spikes of Odontoglossum crispum, arranged over maidenhair ferns, was shown by Messrs. Duchesne and Lanthorne, Watermael, Brussels, and as the varieties were almost all white ones, this was a very chaste display, and one that commanded the attention of all the lady visitors. A gold medal fell to Messrs. A. and G. Jannsens, Merxem, Antwerp, for a collection of orchids wherein Miltonia vexillaria was very fine, with Cattleya Schröderæ, the bright C. Lawrenciana, C. Mendeli, Cymbidium Pauwelsi, and the deep crimson-purple Odontoglossum crispum roseum. A corner group of Phalænopsis Rimestadiana was very effective, chiefly because the exquisite white flowers, borne on graceful spikes, were placed in a dark corner of a rather dark salon, and against a dark background. The beauty of these blooms, and the number of plants growing on a central branching tree stump, arrested attention from those passing through to see the floral designs.

M. C. Maillard, St. Andre lez Lille, won a gold medal for a collection of varieties or hybrids from odontoglossums, and in a very attractive group he had O. concinnum, O. eximium, the yellowish O. Loochristiense, O. Aireworth with bluish tinting; O. Doris, O. Charlesworthi, carrying a patent of nobility in its Harryanum lip; and the very charming Odontioda Ajax, with yellow lip and rosy-crimson sepals and petals.

Lastly we come to the Salon Pauwels, a smaller room than the one occupied by M. Lambeau, but one that was grandly filled by Messrs. Theodore Pauwels and Co., Meirelebeke, Ghent, with splendid orchids arranged with great taste and grace. A bank of Phalænopsis Sanderæ, P. Rimestadiana and P. Schilleriana, had an edging of Oncidium concolor. The noble Eulophiella Hamelini, carrying heads of big rose-purple flowers on stout spikes 5ft. high, was the central feature of one mound; each spike carried over two dozen fleshy blooms. Behind this rose Cymbidium Alexanderi and the pink forms of C. Pauwelsi, while a fine Chysis-bractescens hung high over all. The finest grouping, however, was of miltonias, cattleyas, Oncidium concolor, and odontiodas, but it was the background of somewhere about fifty grand spikes of Cymbidium Pauwelsi (C. Lowianum and C. insigne), set over Cattleya Schröderæ and Dendrobium Schröderianum, that was the grand and striking feature of a glorious exhibit. Nothing like such a display of splendid cymbidium spikes has ever been seen at once before. Messrs. Pauwels received hosts of medals for such gems as Lycaste Skinneri Hellemensis, deep rose; a fine branching spiked Phalænopsis Schilleriana, and a well-grown and especially fine form of Cœlogyne pandurata with eight very large green and black flowers; a huge Masdevallia Harryana; Cypripedium Alcibiades Roi Albert, with wonderfully broad, white, green-based dorsal sepal; a grand white form of Lycaste Skinneri named La Perle, a real beauty; and for Odontioda Vuylstekeæ Reine des Belges, a richly-hued beauty in the way of O. Coronation, but with rosier ground colouring. Besides gold, silver-gilt, and silver medals, the Messrs. Pauwels secured the fine work of art offered by M. Firmin Lambeau.

AN EFFECTIVE DISPLAY OF PALMS AND FERNS, GHENT.

BRITISH-GROWN ORCHIDS.

The larger part of one salon was occupied by Messrs. Charlesworth and Co., Hayward's Heath, this firm bringing over a truly noble contribution to the great show. Palms formed an excellent background, and ferns and moss were used as a base for the growing orchids. Right up amid the palms were the golden spikes of Oncidium Marshallianum and the softer hued Cymbidium eburneo-Lowianum, and the purple Odontoglossum Thompsoni. A comparatively small plant of Cymbidium Humbolti figured near the centre, and all over the group rose charming spikes of Odontonia Edna, Odontioda Bradshawiæ, O. Charlesworthi, O. Diana, O. Lutetia, O. Latona, Odontoglossum illustrissimum Black Prince, O. Wilckeanum

Imperator—a grand variety; O. Dora, O. Aireworth, the heavily blotched O. crispum Ganda, with cattleyas and miltonias in abundance, lælio-cattleyas and brasso-cattleyas, and such choice things as Eulophiella Elizabethæ, with three fine spikes; the black and green Cœlogyne pandurata, Aonia polystachya, with a little cloud of tiny white flowers; a fine form of Phaius simulans, and the bright yellow and carmine Brasso-catlælia Joan, var. Rayon d'or. There were other good things, but these must suffice in connection with a group that was ever a centre of admiring throngs, and which secured a charming work of art as prize.

A splendid bank of orchids in one of the salons was evidence of the enterprise of Messrs. Stuart Low and Co., Bush Hill Park, Enfield. The arrangement was excellent, the evil of crowding having been carefully avoided. There were excellent specimens of Cattleya Trianæ, C. Schröderæ, Dendrobium Wardianum, Lælio-cattleya Dominiana, Brasso-cattleya Imperatrice de Russie, B.-c. Langleyensis, B.-c. Fowleri, Oncidium lamelligerum, with spikes several yards long; Odontioda Charlesworthi, and a fine form of Odontoglossum Harryano-crispum. The group was edged with the drooping spikes of the golden Oncidium concolor. A work of art was awarded to the Enfield firm.

Sir Jeremiah Colman (gardener, Mr. J. Collier), Gatton Park, Reigate, won prizes for Odontoglossum crispum, a lovely large bush-tinted form; Dendrobium Lady Colman, with large purple-tipped sepals and petals, and a grand lip; and for Odontioda Vuylstekæ var. Lady Colman.

NEW PLANTS.

It must regretfully be conceded that new plants were not a specially attractive feature, but it must also be admitted that in these days a really new plant of horticultural value is not easy to find. In place of imported species, however, it must be remembered that hybrids are now abundant, and every month adds new kinds to the ranks of orchids, etc. At Ghent, the finest new plant was a hybrid pæony, and not a rare tropical plant from some far-off land. There was a general regret that the new primulas and the new flowering shrubs from China, with which we have become very familiar at home, were not exhibited at Ghent.

Messrs. Sander and Sons, St. Albans and Bruges, were the largest exhibitors of new plants, and most of the subjects they showed we have previously commented upon, notably Socratea Forgetiana, which we figured last year in connection with the Bruges Exhibition; the quaintly-cut, large-leaved Trevisia Sanderi, from Annam; Dieffenbachia Sanderi, a Peruvian species, with huge green, cream blotched, and almost stemless leaves; the elegant Alocasia Micholitz, with sagittate leaves and white rib and veins on velvety-green ground; Phœnix andamanensis, Maranta Sanderæ, and the huge Alocasia colossa, with leaves about 3ft. by 2ft. on long stems, green, with cream-coloured mid-rib and side ribs. This firm's new Camellia Fred Sander was a great attraction; it has bright red semi-double flowers, the petals broad and somewhat curled, and finely fringed along the margin; this fringing gives the flower a most distinct appearance; eight good plants, 1½ft. high, each carried from six to twelve large blooms.

Polypodium Mandaianum was staged by Mr. W. A. Manda, St. Albans, and New Jersey, U.S.A., and was as much admired here as elsewhere. M. de Smet Duvivier sent a fine creamy variegated form of Ficus australis, quite showy. Mr. Manda also showed a variegated-leaved Primula obconica, which seemed to have sacrificed size of bloom in giving variegation; Fourcroya Watsoni came from the same source. M. Jules de Cock, Meirlebeke, showed Maranta Oppenheimi tricolor, a free-growing and bright variety, with cream, green, and white colouring.

The most striking new plant in the whole of the great Ghent show was a pæony, a lovely hybrid Moutan variety, that bore four flowers, three of them fully expanded, and very much resembling huge salmon-buff double begonias! At the base of each petal, down almost out of sight, was a rich crimson blotch. Everybody persisted in calling this the Yellow Tree pæony, but it was a lovely thing. It flowers naturally early in June, and is quite hardy, and so it misses the late frosts that so often trouble the flowers of P. Moutan. M. Lemoine, of Nancy, told us—and he, by the way, was the raiser and exhibitor—that this new pæony, Pæony hybrida La Lorraine, was the result of crossing P. lutea and P. Moutan var. Queen Elizabeth, the latter salmon tinted.

The comparatively new white, sweetly-scented Viburnum Carlesi was capitally shown by Messrs. J. Blaauw and Co., of Boskoop, and we gathered that it is being grown very extensively in the Boskoop district. This is a charming early-flowering hardy shrub, with rondeletia-like clusters of white, fragrant blossoms.

M. de Smet Duvivier, Mont St. Amand, presented a very pretty, finely-cut maidenhair named Adiantum Makoyanum; Dracæna Deremensis Warnecki, lined with white on green; the deeply-cut Philodendron Duvivierianum, and Pollia condensata, a tradescantia-like plant, with creamy-white and creamy-green variegation on its green, broadly lanceolate leaves; the plant is less than a foot high as shown, and should possess attractions for lovers of stove plants.

An interesting exhibit of plants introduced from China and Japan was made by M. Maurice L. de Vilmorin, Les Barres, Loiret, France. The examples were all small ones, however, and so did not do themselves justice. They were chiefly shrubby kinds, and some of them were quite new, while others have been known for some time. M. Vilmorin published an illustrated catalogue of these introductions, and members of the jury were able to take one, and thus the collection was rendered the more interesting. In this catalogue were coloured illustrations of Pyracantha crenulata Yunnanensis, Pinus Armandi, Chrysanthemum indicum, and Rodgersia pinnata superba.

NEW HOLLAND PLANTS.

Hitherto it has been possible to say in the reports of the Quinquennial exhibitions held at Ghent, that while many of the beautiful greenhouse plants from Australia and the Cape had been practically banished from British gardens, they were still held in high estimation by owners of garden lovers in Belgium. This no longer holds good in an unqualified manner. On this occasion there was evidence that while still grown in considerable numbers in the district of which Ghent is the centre, they are less popular than at any previous periods. The entries in a few of the classes were fairly good, but in some it was otherwise, and, while numerous specimens exhibited were of considerable proportions, some lacked the freshness and vigour which bespeak the close attention and the culture which are usually bestowed upon plants when at the zenith of their popularity. While the display of these plants was not equal to that which we have been accustomed in this old Flemish town, yet the collections shown were such as to form a good feature and to afford pleasure to those who appreciate the distinctive charms of New Holland plants, and have seen with regret their gradual decline in public favour in this country.

Classes were provided for collections ranging from six to fifty plants, and one of the most noteworthy of these was that for six specimens exhibited by M. Firmin de Smet, Vinderhaute-lez, Ghent. This comprised a large finely-flowered specimen of Diosma ericioides, an example of Erica arborea alba, about seven feet in height and clothed with its snow white blossoms from the apex to the rim of the pot, Acacia armata, a huge, densely-flowered bush at least twelve feet in height and fully as much in diameter, and a huge pyramidal specimen of A. verticillata about ten feet high and splendidly flowered. M. F. de Smet obtained the premier award—a gold medal—for a collection of ten acacias distinct, but the specimens differed so appreciably in merit that the group was hardly so satisfactory as one could wish. Some were remarkably fine, while others were decidedly poor. In a second class for large collections M. F. de Smet was again awarded a work of art, and staged many admirable examples of cultural skill.

In competition for the prizes for fifty hard-wooded plants, M. Firmin de Smet was awarded the first prize, a work of art, with the felicitations of the jury, and deservedly so. The specimens were of comparatively large size, characterised by freshness, and finely flowered; and of special merit were Eriostemon linearifolium, probably the finest of all the members of the genus, and Acacia paradoxa, a handsome form of the Armata type. M. Jules de Cock, Meirlebeck, Ghent, was awarded the gold medal for twelve hard-wooded plants, with felicitations, the specimens being of moderate size, but fresh and exceedingly well flowered. The more noteworthy examples were those of Brachysema acuminata, an attractive species of brilliant scarlet flowers, which was regarded with much favour by past generations of cultivators, and large standard specimens of the rich crimson Australian Bottle Brush (Callistemon salignus) and the cream-coloured Sparmannia africana.

Of quite exceptional merit was the group of hard-wooded plants shown and arranged in the western annexe because of the splendid development of the whole of the plants. They were all of large proportions, splendidly flowered, and characterised by the freshness usually associated with plants that have usefulness on their side. Polygala oppositifolia was represented at its best, and Acacia verticillata was simply a huge pyramid of flowers. This fine group was exhibited by Mme. Osterrieth-Mols.

Associated with the New Holland plants in the eastern annexe was a trophy group of stove and greenhouse plants which was arranged in the foreground of a representation of Australian scenery, and produced a striking effect. Conspicuous among the other good specimens were a huge, freely-flowered example of the pure white Rhododendron fragrantissimum, and the rich yellow R. Nuttalli, one of the most handsome of the Himalayan species, a fine example of the brilliantly-coloured Anthurium Scherzerianum Wardi, and a specimen between three and four feet in diameter, and densely flowered of the beautiful soft salmon-red Azalea rosæflora, the finest example of this beautiful dwarf azalea that has yet come under our notice.

Of great interest in this section of the exhibition was the huge collection of New Holland and other greenhouse plants shown by M. Victor Heasset, Ghent, not for competition. The collection included probably five hundred plants, all of considerable size, ranging from begonias to acacias, from agaves to magnolias, and from clivias to eucalyptus. M. Heasset was awarded a work of art for his wonderful collection.

Messrs. Stuart Low and Co. contributed liberally to this section, and were awarded the gold medal for a collection of fifteen specimen New Holland and Cape plants, and silver-gilt medals for ten acacias, distinct, and twenty plants of the fragrant Boronia megastigma.

FERNS.

These elegant plants were freely displayed, and many of the large-growing kinds now rarely grown at home could be seen here, making huge specimens.

A very interesting group of ferns and selaginellas was disposed in one corner of the annexe by Madame Ghellinck de Walle, Chateau de Wondelgen. The selaginellas, in wide pans, were particularly good, notably S. varians, S. Mertensi variegata, M. cuspidata, S. Kraussiana aurea, S. Watsoniana, S. cæsia, the very pretty S. mutabilis, and the tiny S. elegans, S. rubricaulis and S. albo spica. Adiantum Glory of Mordrecht and Nephrolepis elegantissima were the finest ferns.

Lomaria Drapsiana, from M. L. J. Draps Dom, Laeken, is a fine fern with a spread of

five or six feet, its narrowly-divided fronds making up a large rosette of elegant green-ness, nearly four feet high, the young central fronds of paler green rising well above the older fronds. Microlepia speluncæ was a fine example of an old fern, also shown by M. Jules Dom.

The Glory Fern (Adiantum Gloire de Mordrecht) is evidently as much a favourite on the Continent as at home, because of its elegance and its freedom of growth and ease of culture as compared with its near relative A. Farleyense; Messrs. Draps, Dassonville de Forest, Brussels, showed it well, but especially fine were the lovely specimens from Messrs. Bier and Ankersmit, Melle lez Gand, as in these the frilling of the pinnæ was particularly good, and the pink young fronds rose well above the older frondage. This is possibly a variant on the Glory Fern, as it was labelled Roem de Mordrecht. This firm displayed the newer nephrolepis in fine style, and their N. Piersoni compacta was a picture of health and beauty; and so was Adiantum æthiopicum elatum, 6ft. across.

M. Jules de Cock, Meirlebeck, was a large exhibitor of ferns, and conspicuously fine in his prize collection of thirty specimens were them at the Ghent Quinquennial Exhibition, for there they are so largely and well flowered that the glorious colour effects are well-nigh sufficient to take the breath away of those who see them for the first time. There were fifty-four classes for Indian azaleas, of which four were for collections of one hundred plants, and twelve for collections of fifty plants. It is not difficult to understand that, with so large a number of classes, the number of plants shown must be enormous if the classes are well filled. The competition is invariably of the keenest, and it is by no means uncommon to see four or five hundred plants in one class. The conditions of competition are so arranged as to obtain, as far as practicable, an adequate representation of the several sizes of azaleas that are the most plentiful in Ghent; usually the largest number of plants exhibited are those ranging between 18in. and 30in. in diameter. The flower production is simply marvellous, and there are at the Exhibition many hundreds of plants that are so densely flowered as to render it well-nigh impossible to push the point of a pencil down between the blooms without injury to them. The whole of these are arranged in meter, but hardly so attractive and densely flowered as when of a smaller size; M. Louis Chabet, an effective single variety of a red-purple hue, more valuable for the contrast it affords to the brilliantly-coloured varieties than for decorative purposes generally; Madame Leon Chabet, an exquisitely beautiful variety, with large, single, soft pink flowers, which are elegantly frilled at the margin; Phœbus, an effective semi-double variety, with flowers of a brilliant orange-scarlet hue; and Mdme L. Coppé, a charming semi-double variety, with flowers of a soft pink hue, deeper pink in the centre. Messrs. Sander and Sons, St. Albans and Bruges, followed closely for second place, and were awarded a gold medal. Their specimens were a size smaller than those forming M. d'Haene's collection, but they were uniformly perfect throughout, and the varieties included a goodly proportion of those of comparatively recent introduction. Among the finest of these were M. Victor Cuvelier, rich rose-purple, with bright, deep orange-red blotch on the upper segments; Liebig's Superba, a fine variety, with brilliant rose-carmine flowers; Vervaeneana, one of the most beautiful of the salmon-pink semi-

A BRILLIANT DISPLAY OF INDIAN AZALEAS, GHENT.
The plants depicted were the usual nursery size in five-inch pots.

Platycerium grande, P. Willincki, a fine Cyrtomium Rochfordi, its fringed fronds being greatly admired; Polypodium glaucum cristatum, and Adiantum Farleyense. M. de Cock's collection of Stag's-horn ferns was of special interest, because it included Platycerium alcicorne, P. a. majus, P. Hilli, P. grande, P. perfectum, a bold, tall grower; the very broad-fronded P. angolense, P. biforme, P. grande, P. Willincki, and P. Hilli majus.

INDIAN AZALEAS.

Because of the immense extent to which ornamental plants are cultivated by its citizens, Ghent has long been spoken and written of as the "City of Flowers," but it would be almost equally appropriate to designate it as the "City of Azaleas," because of the important position occupied by these flowers in the nursery industry. Indian azaleas are grown to an extent and in a manner that no one who has not been to Ghent, and had an opportunity of seeing the plants in the numerous nurseries, can have an adequate idea of. It might, perhaps, have been more correct to say that those who have not seen the great central hall to form a series of beds and borders; and the enormous masses of scarlet, rose-coloured, pink, and white flowers form a series of displays that have certainly not been surpassed at Ghent or in any other part of the world, and well worth a long journey to see them under such favourable opportunities as those which the quinquennial shows afford.

One of the most important of the many classes provided for Indian azaleas was that for forty specimens, and in this the chief prize—a gold medal presented by the Queen of the Belgians—was awarded to M. A. de Haene, Ledenberg, Ghent, who had a very striking group that was rather unequal in the development of the specimens. Exceptionally fine were the huge examples of Dame Melanie, an exquisitely beautiful variety, the flowers soft pink with carmine blotch; Roi d'Hollande, one of the finest of the scarlet varieties; Temperance, a semi-double variety, with flowers of a lovely mauve shade; Géant, soft rose-red, semi-double; Hexe, the dwarf scarlet variety now so largely grown for Covent Garden Market—the specimen was nearly four feet in diadouble flowers; Baronne de Vrière, pure white, with an occasional splash of bright red; Magnifica, a beautiful rose-coloured form; Julius Roehrs, a highly effective variety, with large, finely-formed flowers of the richest rose-crimson hue; Mdme. J. B. Wolfs, a superb pure white variety, the flowers of the largest size, and remarkable for their substance; Hermann Seidel, a magnificent variety, with glowing rose-coloured flowers; Mdme. Louis Van Houtte, one of the finest of the salmon-coloured azaleas; Frans Zirovi, a beautiful semi-double, the flowers delicate pink, marked with a small, deep pink blotch; Jean Van Eyck, a glorious variety, the flowers of the brilliant hue which renders Roi d'Hollande so valuable for decoration, but much larger and of finer form; and Princess Clementine, a pure white flower of great excellence. Messrs. Sanders' collection was of great educational value, inasmuch as it afforded visitors an opportunity of seeing the finest of the varieties in their respective colour classes in specimen form. An admirable finish was given to the group by a marginal line of plants of Julius Roehrs, and a semi-double, pure

white variety, with heads of bloom about two feet across, and arranged alternately.

In the centre of the great hall was a huge geometrical arrangement of azaleas, which produced a rich display of colour, but its formality detracted somewhat from the general effect. The whole of this display was produced by Messrs. J. B. Haerens and H. Wille, Ghent, and the several collections formed their contributions to a considerable number of classes in which the plants had to be of a quite small size. Some were arranged in wedge-shaped blocks of distinct colours, while in the case of others the colours were mixed. With regard to varieties, it will suffice to say that the firm exhibited a beautiful deep pink semi-double flower, under the name of Mme. Haerens that appears to be well deserving the attention of cultivators. The variety was shown in both bush and standard form, and in each it was highly satisfactory. They had also Vervaeneana rosea, a deeper-coloured form of Vervaeneana of much merit, and Haerensville alba, a semi-double with pure red colour; Konigen Elisabeth, a beautiful semi-double pure white flower of large size and with frilled segments; Professor Emile de Nobeli, a semi-double flower of the largest size, flushed with carmine in the centre, and quite free from blotches; Louis Vervaene, a superb semi-double, the flowers of large size, and the colour a delicate salmon-pink; Lucien de Cock, a superb semi-double, the flowers of medium size, and with elegantly frilled margins, the colour glowing crimson. M. Auguste Haerens, Somerghen, who was awarded the second prize in the class, had a number of good novelties, the best being President Alexis Caillier, a semi-double, the flowers large and of a brilliant carmine tint; Lady Roosevelt, a very large semi-double flower of the softest salmon-pink, shading to white; Winifred Haerens, a large semi-double, the colour glowing rose-carmine, suffused orange in the centre; Etoile de Belgique, a remarkably distinct semi-double flower with long, pointed, and regularly arranged segments, the colour rich crimson, a quite new type.

but the colour of this old and popular variety is hardly equal to that of some other of the rose-pink varieties when under the influence of a strong light.

A large-flowered semi-double variety, shown by M. A. Haerens under the name of Brillianta Belgica, has the promise of being of much value for decorative purposes where strong colouring is desired; the colour is brilliant rose-crimson, and appears to great advantage under the influence of a bright light.

The class for a group of azaleas arranged on a space of about 80 square yards, the plants being on twenty-inch stems, was sufficient to test the resources of the largest exhibitors, but evidently it imposed no strain on the Belgian growers, for the specimens were some of the best of those of medium size in the exhibition. Messrs. E. Verrae de Vos and Co., Gwynaerde, Ghent, who won the work of art offered as the first prize, had a magnificent collection, the specimens about thirty inches in diameter, superbly flowered, and highly finished. The

THE FINE DISPLAY OF CALADIUMS AND AROIDS, GHENT.

white flowers that was made note of as a fine addition to the white azaleas.

A work of art was presented by the members of the Ghent Press as the premier award for a group of twenty specimen azaleas. Here M. Charles Verbawen was successful in obtaining premier honours, his group consisting of medium-sized, finely-flowered specimens. Messrs. Maenhout frères, Mont St. Amand, Ghent, were the winners of the gold medal offered as the second prize with medium-sized, well-bloomed bush plants. Very fine in the first-prize group were the rich scarlet Le Flambeau, the brilliant pink Professor Wolters, and Vervaeneana.

New azaleas were of much interest, and the collection with which Messrs. Haerens and Willes succeeded in winning the work of art offered as the premier award contained several surprising varieties that were a great advance on those in cultivation. Very fine are Haerwill's Pink Pearl, a beautiful semi-double variety, with large pink flowers, with a deeper tint on the upper segment; Juge de Huyek, a semi-double flower of the largest size, but free from coarseness, with a frilled margin, and of a glowing rose-

Very brilliant was the display produced by the azaleas arranged by M. Auguste Haerens on about 250 square yards. The large number of plants required for filling this immense space were splendidly flowered, and the heads of bloom ranged from eighteen to thirty inches in diameter, and the flowers were throughout in a high state of development. The work of art offered as the first prize was awarded to the exhibitor with felicitations, and deservedly so; he had certainly not overlooked the fact that tasteful arrangement was not less necessary than plants evincing cultural skill of a high order. Very pleasing was a large bed of Blushing Bride, a beautiful semi-double variety, with large flowers tinted salmon-pink, deeper in the centre, but quite free from blotches or other markings.

A very striking colour effect was produced by the fifty densely flowered bush specimens of Mme. Van der Cruyssen, for which M. A. d'Haene was awarded the first prize in the class for fifty plants of any one double variety The specimens were splendidly flowered, and the colouring under the soft light of the exhibition hall was very pleasing,

uniformity in size, form, and finish of each head of bloom suggested a huge bouquet, in which much taste had been evinced in the arrangement of the flowers. The varieties were much the same as those already enumerated, and therefore included the pick of the best in cultivation. Frau E. Richter, a glorious pink variety, has not been mentioned, and must therefore have attention drawn to it. Not less deserving of notice is Oberst von Kutchinksy, which may best be described as a semi-double Roi d'Hollande, and therefore of immense value.

The group of twenty-five pyramidal specimens for which Messrs. Sander and Son were awarded a work of art was highly attractive and of great educational value to those who give their attention to the cultivation of Indian azaleas in this form. Every one of the specimens was perfect in training and flower development, and served as an excellent model for pyramidal specimens. Not less noteworthy in its mass was the splendid group of plants, in thirty varieties, of the usual saleable size, exhibited by this firm, who, in the face of a very strong competition, were awarded the work of art offered as the

last prize. The gold medal collection in the same class from M. Paul de Schryver, Loochristy, and M. A. Vervaet-Vervaen, Meirlebeke, were all of great merit.

HARDY AZALEAS.

Very effective were the rich colour displays afforded by the great groups of the varieties of Azalea mollis. The rich shades of orange, yellow, and fawn were a pleasant change from the colours of the rhododendrons and Indian azaleas, but in a few cases they were not arranged with due regard to their environment. In the case of the groups arranged in the eastern annexe they were so placed as not to clash with the colours by which they were surrounded, and consequently they produced a rich and most pleasing effect. Here were the contributions to the class for big specimens, and Messrs. de Reuse frères, Saffelaere, Ghent, were awarded the gold medal for specimens that were simply enveloped in flowers. In a second class for collections the same firm were awarded a gold medal, with felicitations.

Ghent azaleas were shown in association with the Indian varieties by M. J. P. Hartman, Ghent, but, although the combination of colours produced a bright display, the effect was not particularly pleasing when seen at close quarters. Opinions may differ upon this point, but there can be no difference as to the award of a gold medal having been well deserved.

PALMS.

Though less startling in their colour effects, the palms were a grand feature of the Ghent show, and one wonders how so many growers had accommodation for such giant specimens as those which towered in the warm salle. It was not as though only a dozen or so of specimens were brought, but there were scores of big specimens ranging from ten feet to thirty feet in height, and the fine effect produced by those graceful plants can readily be imagined, an effect we lose in our British exhibitions because so few people cultivate, or have conveniences for, such fine examples.

M. Francois Spae, Melle, Ghent, had a grand lot of palms—indeed, such palms as one sees at Ghent Show are never seen at British exhibitions, though at Kew, Edinburgh, Cambridge, Dublin, and one or two private gardens as fine and finer specimens are to be found. Palms have such a special grace that it is a thousand pities more kinds are not grown at home. M. Spae had Ceroxylon niveum in fine condition, the white undersides of its leaves demanding attention; Pinanga Kuhli is another striking kind; but far above these towered Kentia Dumoniana and K. Forsteriana, while a gigantic bushy mass of Rhapis aspera filled the centre of a large group. Kentia McArthuri, the purple-tinted, broad-leaved Kentia Lindeni, the red-stemmed Cyrtostachys Renda Duvivieriana, the fine Caryota Schilleri, and a very big, 15ft.-high Areca Baueri were other fine palms shown by M. Spae, who won many prizes.

Right across the extreme end of the great annexe the Société Horticole Gantoise arranged one of the finest displays of palms ever exhibited. It consisted of a hundred specimens, and it would easily have filled one half of the Royal Horticultural Hall, lengthways. A fine work of art fell to this company. We pick out a few of the more striking kinds from this wonderful collection, and these few must include Ceroxylon andicola, the Wax Palm; Caryota elegantissima, Elais guineensis, the Oil Palm: Astrocaryum mexicanum, with glaucous leafage borne in a great crown at the top of a stout stem; a great Livistona rotundifolia with leaves about six feet across; Kentia Lindeni, twenty-five feet high; the curious Kentia pendula, and a Corypha australis of splendid size and development, and just the sort of plant to always occupy a central position at the Vincent Square exhibitions—about eighteen feet high and twenty-five feet across.

Phœnicophorum seychellarum, with its broad leaves and spiny stems, was well shown by M. T. Piers, and also by M. Leonard Gyseback fils, the latter receiving a silver-gilt medal for his specimen, about seven feet high.

The graceful and immensely useful Phœnix Roebelini was finely shown throughout the hall, and plants of varying size were displayed, but all showed excellent culture, being clean and healthy, and feathered to the pot rim. M. J. P. Hartman, Ghent; M. Theophile Piers, Melle; and The Flandria Company, Bruges, all showed this grand palm finely, but the latter had the larger number of large specimens, and secured therewith a special gold medal. M. Guillaume Gyselinck, Melle, also had these palms in fine condition. By far the finest specimen of Phœnix Roebelini was one about nine feet high, clothed to the tub in elegant leafage; it was shown by La Croix Co., Calcken, and secured a special award.

The finest set of eight Kentias came from the Flandria Company, Bruges, and were grand examples of K. Canterburyana, K. Kersteniana with slender stem; K. Sanderiana, also slender-stemmed, and K. Alberti. K. Belmoriana, K. pendula, and K. Dumoniana. The same firm, now renowned for its fine palms, put up a magnificent collection of fifteen specimens, staging grand examples of Phœnix Roebelini, about six feet high; a giant Kentia Belmoreana, Areca lutescens, Rhapis humilis, twelve feet high; Chamærops excelsa, the glaucous Locos Bonnetti, and a wide-spreading Livistona rotundifolia, with big fan-like leaves. Many high awards fell to this company.

A PICTURESQUE GARDEN SCENE, GHENT,
Arranged in the Western Annexe of the Great Hall.

STOVE PLANTS.

In the great central hall of the exhibition the brilliant colouring of the great masses of azaleas and rhododendrons made the eyes tired very soon, and so it was a great relief to turn aside into the big salle where the stove and foliage plants were arranged in massive groups and great beds and borders, a fine, graceful, and soft effect being produced by giant palms, huge ferns, big

aroids and bromeliads, with crotons, alocasias, caladiums, and anthuriums lending some colouring here and there. Here, as elsewhere, a garden effect had been created, and there was nothing at all formal about the "tout ensemble" produced under the direction of M. Charles Pynaert.

Messrs. L. Van Houtte père, Ghent, won the gold medal for a group of thirty specimen aroids, and disposed huge examples in tubs, many feet across, of Deiffenbachia Jenmani, Alocasia argyrea, Anthurium crystallinum, A. Scherzerianum, Phyllotænium Lindeni major, Philodendron Islemani with white and green variegation; Nephytis picturata, and giant caladiums. Plants of this character are now seldom seen at British exhibitions, though formerly some of them were quite popular. The Comte de Kerchove's prize, a work of art valued at 500 francs. offered for the best twenty-five striped foliage plants, was won by Messrs. L. Van Houtte père, with enormous specimens of Nephytis picturata, about 7ft. across; Maranta vittata, the yellow and green Pereskia Godseffiana, Dracæna Goldieana and D. Sanderiana, Vriesia Moensi, a handsome bromeliad, with yard-long green, cream, and white striped leaves; Anthurium crystallinum, Croton Leonie, C. Lord Roberts, the handsome Alocasia Kerchoveana, etc.

Messrs. L. Van Houtte continued their winning way through many classes, and secured the work of art offered by the Committee of the Universal Exhibition for forty miscellaneous plants, flowering or non-flowering. Here, again, they had enormous specimens, the smallest needing a dozen square feet at least to show itself off to advantage. Kinds already noted were repeated here; but other fine things were Phœnix Roebelini, Licuala grandis, a big Erythrea cristi-galli, Cocos Weddelliana, Zamia Lehmanni, and Bougainvillea spectabilis aureo-variegata. This was an enormous exhibit that filled a great semi-circular bed backing against the wall of the salle.

We did not notice anything strikingly new among dracænas, though these elegant stove plants were freely exhibited. Such kinds as D. imperialis. D. amabilis, and D. Baptista, long familiar, were much in evidence. D. Desmetiana, creamy-white, green, and pink, from M. J. E. Story, Allée Verte, Ghent, and several other growers, was very bright.

M. Le Smet Duvivier, Mont St. Amand, exhibited marantas finely, and these handsome foliage plants attracted considerable attention by reason of their striking markings. M. Closoni, M. Chantriere, M. vittata, M. Porteana, M. Makoyanum, M. rosea picta, with very large leaves, M. Bachemiana, which seems to have a pinnate leaf imposed upon its entire greyish leaves; the miniature M. Wioti, and the good old M. Zebrina were a few of the best in a large collection of big specimens. Another grand lot of marantas came from M. Alexis Dallière, Ledeberg, and secured a gold medal.

There were no finer crotons in the Exhibition than those shown by the Société Horticole Gantoise, who presented fifty specimens. Some of these had their branches tied down to make them low, broad plants; while others were enormous bushes 6ft. to 9ft. high, and of greater width than height. The smallest specimen was a yard wide, so the effect produced by fifty specimens, with foliage of varying brilliancy and markings, may well be imagined. Especially good were the varieties Jeanne de Smet, M. Florin, Mdme. Riffauty, Mdlle. B. Fournier, Lord Rendle, and Mdme. Lucien Linden among the broad-leaved sorts; the latter has leaves 4in. to 5in. broad, and 7in. to 18in. long, and the colouring is golden-yellow over brown. Of the narrower-leaved crotons the most imposing were Leonie, Countess Worteli, and Masangeana. We must not omit Paul Garnot, another broad-leaved sort, the new foliage being rich yellow, and the old leaves scarlet and dark purplish-brown. The special prize won by the company in this class was a work of art presented by M. Victor Heursel, the librarian to the Royal Horticultural Society of Ghent—a prize richly deserved. For a hundred crotons, M. J. E. Story, Ghent, annexed the premier award. but he showed plants in small 32-sized pots, and staged fairly well-known varieties.

In one of their large displays of a hundred plants, the Société Horticole Gantoise showed a beautiful pan of the exquisite Anœctochilus petola, its golden netting on velvety-green ground making this little bright-leaved orchid a great attraction to all lovers of foliar beauty and high culture. Here, too, was Acanthus montanus, a yard high, with mottled grey and dull green, deeply-cut leaves about 15in. long, an attractive foliage plant; Gloriosum Rothschildeanum, not yet in full bloom: Dracæna Deremensis-Bausei, with a broad white stripe down the middle of the white stripe, was very effective; the largest variegated pineapple we have ever seen; and the broad-leaved spiny, dull green Pandanus pacificus.

Mrs. John Laing, one of the noblest of caladiums, was grandly shown by Messrs. Louis can Houtte père; while Golden Ring, Alexandre III.. T. de Viger, Rose Laing, the lovely pink and cream Raymond Lemoine, and the exquisite pink Rio Janeiro were also included in this firm's collection of a hundred varieties.

M. Jules de Cock presented a collection of cycads, and staged large, spreading examples of Ceratozamia mexicana, Zamia Lehmanni glauca, Encephalartos Vroomi, Zamia Caffra, Zamia horrida glauca, and Cycas revoluta. For this set he received a special work of art.

Of course there were anthuriums of the Scherzerianum and Andreanum sections in plenty. Of the former, the Société Horticole Gantoise had a very fine lot of broad crimson-spathed plants. with a few creamy and white forms, the whole backed up by Andreanum varieties, of which Abel Chatenay, white; Senateur Bast, crimson-scarlet; Souvenir de M. Hardy, deep crimson; and Roi Leopold, blush-pink, were fine.

Mr. Arthur de Smet, Ledeberg, Ghent, filled a large oval bed with varieties of Anthurium Scherzerianum set amid Adiantum Farlevense. Some of the specimens carried over fifty spathes of the most brilliant scarlet hue; but there were others bearing cream. white, salmon, and crimson spathes; and there were numerous forms of the speckled variety Rothschildeanum.

Messrs. L. Van Houtte père sent a collection of economic plants that included bread fruit, caraway, ginger, cardamons, eucalyptus, coffee, sugar, Hevea rubber. tea, cinchona. guava, hemp, aniseed, coca, cinnamon, cocoa, tamarind, etc.

GARDEN, ART, AND FLORAL DESIGNS.

A very beautiful garden, a scenic effect that attracted general comment and admiration, was a combination of ruined temple, rocks, water, grass sward, balustrading, palms, cordylines, and early-flowering shrubs, grouped with great taste and effect by Mdme. Osterrieth-Mols, of Antwerp. This was no little affair of a few square feet, but a large design, covering probably nearly 200 square yards. The general idea was a path leading from an old gateway by flower-bordered lawns up to a ruined temple with Corinthian columns. The temple occupied the high ground, and immediately on its right were towering cordylines and palms, behind viburnums, glowing mollis azaleas, cystisuses, and rhododendrons. In front of the shrubs a sharp, rocky-faced fall led down to a pool of water. Among the rocks were ferns, lowly azaleas of the amœna type, and some blue hydrangeas where grass met rock. On the grassy banks above the pool were clusters of nemesias, and then a group of clematis, Japanese maples, and wistarias came where the rocks broke out again, and cut through the line of the boundary balustrading. Passing back towards the gate, azaleas, wistarias, rhododendrons, and spiræas were grouped in the border, while Primula obconica and dwarf Japanese azaleas studded the small lawn. About the only things that seemed out of place were the amaryllis and anthuriums near the gateway. The whole made up a very lovely exhibit, and if it lacked natural veracity, it did not lack admirers, and scarcely any exhibit in the show was so much admired. The talented lady artist received a special work of art as prize.

Several exhibits of floral art were distributed through the salons, but, on the whole, we thought the various items were somewhat overdone, flowers being used with prodigality and, in some cases with barbaric taste. A display from Amsterdam was one of the best.

CARNATIONS.

Never before have carnations been so largely shown or so finely displayed at Ghent as on this occasion, and it is with no small amount of pleasure we state that by far the greater portion of the carnation display consisted of British-grown flowers set up by British firms.

Mr. C. Englemann, Saffron Walden, covered himself with glory by filling a space of about 640 sq. ft. His was a tremendous effort, and contained about five hundred and forty dozen blooms. There was a sort of pergola arrangement along the back with bunches of bloom set in the hollow bamboos, accompanied by asparagus and smilax sprays. Two high tripods, one filled with White Wonder and the other with Baroness de Brienen, were prominent features, and towered above the vases and baskets of Mikado, Geisha, and Sunstar, White Enchantress, Rosette, Mrs. C. F. Raphael, the vivid Red Carola, Carola itself, and many another fine variety. Mr. Englemann won a gold medal for a dozen novelties introduced since 1910, and another gold medal for varieties not yet in commerce. In the former class, the varieties were Dorothy Gordon, Variegated Carola, White Wonder, Beacon, Lady Mever, My Rose, Emperor, Rosa, Lady Northcliffe, Sunstar, Salome, and Pioneer. Among his new seedlings Mr. Englemann had a very large dark heliotrope variety, a curious creamy-pink flower, and a rose and red-striped form of considerable beauty. Mr. Englemann won an Object of Art for two dozen varieties and three silver-gilt medals for other items. He grouped his competitive exhibits around his non-competitive one, and so produced a grand display; indeed, one of the finest ever set up. Mr. Englemann's effort was such a great one that he was about the last competitor to finish on the Friday morning but he secured an extra and special prize for his general display.

A pretty contribution from Messrs. Wm. Cutbush and Son, Highgate, consisted of fine flowers, set up lightly in elevated stands and baskets, with smaller vases below, and some palms and ferns among them. A special prize for a scarlet carnation was won by the rich scarlet Mrs. Lucy McKinnon. King Manuel, a pale salmon-pink; Lady Alington, deep salmon-pink; Edna, heliotrope; the flaked and bright Marmion, White Wonder, White City, and the bright buff and red variety named Mrs. W. Astor, Scarlet Glow, and Britannia were other conspicuously good varieties.

All the way from Cheltenham Messrs. Young and Co. brought over blooms that thoroughly enhanced the firm's reputation. The flowers were disposed in stands and vases of varying height, with an accompaniment of asparagus, ferns, and palms. The crimson Duchess of Devonshire was the central feature, but Mrs. Greswold Williams, Hon. Lady Neeld, A. S. Montgomery, lavender-rose; Hon. John Boscawen, blush pink; Mrs. C. W. Ward, deep rose-pink; the lovely pink Mayday, the ever good Britannia, and the chaste White Wonder, were all displayed in capital fashion, and the blooms seemed to appreciate their journey into "a far country."

Those who have seen Messrs. Stuart Low and Co., of Bush Hill Park, Enfield, put up a large circular group of carnations in the centre of the Royal Horticultural Hall, Westminster, will be readily able to imagine the kind of display this firm made at Ghent, for

Mr. PHILIP LADDS wrote 8th March, 1912.

"Dear Sir,—In consideration of the generous and prompt manner in which you settled with me, following on my claim on your Company for glass broken by the severe storm on March 4th, I wish to convey my best thanks to you personally for the courtesy and fairness shown me when here on the following day, and to the Company for their unquestionably fair method of business. I do not desire a repetition of the storm, but in these untoward occurrences it is very gratifying to know that 'The Hailstorm Insurance Co.' are always ready to extend every advantage of their Company to the Glass-house owner.—Yours faithfully, FRANK W. LADDS (Manager)."

Why not become a Regular Reader?

was planned on similar lines, and was very effective. Towering stands of blooms, enclosed with tall palms and hanging baskets of flowers to make up a full and bold central feature, and round this were grouped vases and stands of bloom over a groundwork of green moss and small ferns and maiden. Varieties were numerous, but we may mention the excellent flowers of Cinnabar, small, but sweet and pretty; Satin Rose, suggestive of pink ice-cream; British Triumph, deep crimson; Baroness de Brienen, probably the most popular salmon-blush variety of the day; Mrs. C. F. Raphael, a bold rose-red bloom; the glowing Marmion, Carola, the mighty crimson maroon carnation; and Mikado, one of the best heliotrope varieties.

Another fine exhibit from a Britisher was the one set up pleasingly by Mr. A. F. Dutton, Iver, Bucks. Mr. Dutton filled a large corner, opposite Mr. Englemann, near the steps up to the Salon. He used glass vases and also some tin ones, and he had sufficient palms and ferns to hide the sandy flooring. He had beautiful blooms of Winsor, White Perfection, Mikado, and the Yellow Sunstar in the same vase, Mrs. A. F. Dutton, Beauty, very bright; Scarlet Glow, and the lovely Enchantress.

A capital group of cut perpetual-flowering carnations, every flower a good one, and the arrangement of the best, was set up by Mr. T. J. Dinn, Clingendaal, La Haye, Holland. It was a display that would have done credit to any firm. The variety Baroness de Brienen was made the most of, great bouquets of blooms, as well as growing plants, being arranged through the centre, flanked by Lady Alington, and with Mikado in front to break up the colouring. Enchantress was no less beautiful, and Mrs. C. W. Ward was grand, but Colossus did not appeal to us, though Carola, Triumph, Mary Allwood, and Mrs. C. F. Raphael were of high merit and beauty.

Mr. Draps staged an exhibit of cut carnations which gave evidence of skilful cultivation; he put up his flowers in tall glass vases, à la Dutton, and displayed first-rate examples of Benora, Triumph, Duchess of Devonshire, Mikado, Britannia, White Wonder and Empire Day. This group was well finished off with ferns, while ferns and palms among the stands and vases prevented any suggestion of thinness or barrenness, though the wooden stools carrying the vases were a trifle obtrusive in places.

The Société Horticole Yproise, Ypres, Belgium (Mr. Bouckenoghe), presented a large group of carnations, but his blooms fell far short of the Britishers' in quality, though Rose Pink Enchantress, Cinnabar, Empire Day, and Triumph were very well represented. It was in new seedlings, howhower, that this company excelled, for they had scores of new flowers that included some distinct colourings, especially among carmine and rose shades, and gorgeous buff or yellow ground fancies, while one fringed white seedling attracted a fair amount of attention from the English growers.

THE DUTCH EXHIBIT.

A quite good display set out on a large pear-shaped lawn indicated some of the special features of the Aalsmeer district in Holland. At the broader and higher end grandly-flowered lilacs were massed with Acer Negundo, and all around the growing plants vases of long-stemmed bunches of bloom were massed in prodigal fashion, and for beauty and fragrance this exhibit was superb.

Imagine about three hundred vases of superb spikes, chiefly of Marie Legray and Souv. de Leon Spaethe, lilacs, grouped in a bold crescent-shaped group, with a few plants of Pyrus malus among the low vases of the white lilac towards the lowest point of this crescent; a grass lawn in front; on one side a large group, also pear-shaped, about fifty feet long, composed entirely of glorious roses, cut, and set in green vases, with ferns and asparagus sprays between—the varieties Captain Hayward, Caroline Testout, and the lovely Kairserin Augusta Victoria, the latter massed at the widest end of the bed; further, imagine at the narrow end of this fine display, a bed of pink and white hydrangeas over blue pansies, this mass of colour backing up a very beautiful lot of over a hundred perfect specimens of Begonia Gloire de Lorraine, some raised a yard high and others set low among purple pansies.

The whole, as noted, together with borders of fragrant crimson wallflowers and bands of great-headed mignonette, formed a contribution that was a fine tribute to the Aalsmeer growers' enterprise, and formed at once the most fragrant, and not the least beautiful of the many fine exhibits in this great show.

RHODODENDRONS.

Although much less numerous than the Indian azaleas, the evergreen rhododendrons were exhibited in immense numbers, and as they were all superbly flowered they constituted a feature that was equally remarkable for its distinctness and beauty. In most cases the groups of these handsome shrubs had for a background scenic representations of wide-spreading lawns and handsome trees, and in one instance a neat rhododendron garden, as seen in the flowering season. With such combinations the colour effects were rich and striking, and suggestive of the aid these shrubs are so well able to render those who are engaged in the creation of garden scenes. Especially remarkable for their flower production, and rich colouring were the immense number of dwarf bush specimens shown by Mr. A. de Clercq, Chysegham, Ghent, who was awarded two gold medals, one for his mixed varieties and the other for a hundred or more specimens of the charming Prince Camille de Rohan, with its bold trusses of rose-tinted flowers marked with a deep blotch. These two huge groups formed the foreground to the scenic rhododendron garden, and were highly attractive to the visitors. Near by was a group of rhododendrons consisting of one hundred or more standards, carrying large heads, all of which were so splendidly flowered as to suggest huge bouquets of bloom. Mr. F. Späe was exhibitor, and was awarded the first prize, consisting of a gold medal. Mme. Calvalho, a beautiful variety with flowers of a light blush hue, which enjoys a high degree of popularity in British gardens, was finely represented by a huge, splendidly flowered specimen growing in a large tub. This was shown by M. Charles van Geert, and was of interest as evidence of the adaptability of rhododendrons for growing in large pots and tubs for terraces and promenades in both public and private gardens.

A glorious feature was formed in the eastern annexe by the two magnificent collections, each consisting of forty specimens, in competition far the handsome work of art presented by M. Albert Ceutrick. These were exhibited by Messrs. Louis Van Houtte père and Co., and M. Charles van Geert, and in the result the first named were awarded the work of art, and M. van Geert a large gold medal. Many of the specimens ranged from four to five in diameter, and splendidly

AN ATTRACTIVE COMBINATION OF HYDRANGEAS AND RHODODENDRONS, GHENT.

flowered. Among the varieties represented were Cynthia, a beautiful form with noble trusses of rich pink flowers; Helen Waterer, Fiala, Purity, a remarkably fine white variety, Felix Sauvage, Lady Annette de Trafford, Matchless, a superb crimson form with exceptionally large trusses, the popular Pink Pearl, and E. G. Holford. Rhododendrons were used with remarkably good effect in the eastern annexe, and chief among the collections was that shown by Messrs. Bracke frères in the class for forty specimens, for which they were awarded the gold medal offered as the third prize. The group of new rhododendrons shown by Messrs. A. Damme-Verras, Loochristy, was very attractive, but it lost much of its interest from the fact that all the varieties were shown under number. The firm was awarded the gold medal offered as the first prize.

A highly attractive feature was formed by the beautiful Pink Pearl, of which huge groups of splendidly-flowered plants were exhibited by M. C. Vuylsteke, Loochristy, and Messrs. Sander, to whom were awarded gold medals. The last-named firm had also the superb White Pearl in a high state of floral development.

MISCELLANEOUS.

A few words are necessary concerning the fine group of the newer hydrangeas submitted by several Belgian and French growers. M. Moulliere had a number of seedlings on view, but Mdme. Moulliere was still one of the finest forms, and it was grandly represented by great heads of fringed flowers; La Perle was another good form.

Messrs. Vilmorin, Andrieux, and Co., Paris, brought along some good herbaceous calceolarias, and staged these in blocks of distinct self colours; there were no spotted or striped flowers, but pure selfs, ranging from pale lemon to deep crimson.

Messrs. C. van Tubergen, Haarlem, gave further evidence of their work among freesias by filling a large circular bed with varieties of many colours and shades, from palest yellow through lilac and rose shades, to bronzy tints and pink forms. These were all very charming, and no doubt they will greatly extend the culture of freesias.

PRUNUS SARGENTI.

About twenty years have elapsed since seeds of this showy cherry were first received in this country, for in 1893 Professor Sargent, after whom the species is named, sent seed which he had collected in Japan the previous year to Kew. Three years earlier plants had been raised in the Arnold Arboretum from seeds communicated by Dr. Bigelow, but before that date the tree does not seem to have been known outside of Japan, although it may have been distributed with varieties of the well-known P. serrulata, and have remained unnoticed.

The history and botanical characteristics and affinities of the species are given in the "Botanical Magazine," t. 8,411, a figure having been prepared from one of the Kew plants in 1911. Most closely related to P. serrulata, it differs in several points regarding the shape, size, and serration of the leaves and the arrangement of the flowers. Here it has the appearance of forming a small, round-headed tree, but under favourable conditions in its native country it is said to attain a height of 80 feet, with a trunk diameter of three feet. The rose-coloured flowers are borne in clusters of three or four flowers each, and individual blooms are up to one and a-half inches across.

In addition to the beauty of the flowers, the bronzy colour of the young leaves is very pretty in spring, whilst previous to falling the foliage turns to a reddish hue. It requires similar culture to other members of the cherry group, and thrives most successfully in good loamy soil. W. D.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

GENERAL REMARKS.—With the lengthening days and growing power of the sun, more moisture may be given in all the orchid houses. The bulk of the orchids at the present season are in a more or less active state of growth, and the necessary encouragement must be afforded, including an increase of about 5 deg. in higher temperature in all divisions. We find it necessary, with favourable outside conditions, to damp the floors, stages, and among the pots as early in the morning as possible. In bright weather, and when the conditions are drying, the damping should again be done in the middle of the day, and also between three and four o'clock, when the ventilators are closed.

VENTILATION. — With the use of the blinds discretion is necessary in respect to ventilation. It will frequently be noticed, and more especially where lath roller blinds are used, that the lowering of the blinds causes a rapid fall of the temperature in the houses. This is no doubt caused by the cool air passing over the space between the blinds and the glass, and every care is necessary to see that the ventilators are used to counteract such sudden fluctuations of temperature. I am convinced that many young and tender growths are permanently disfigured as a consequence of chills of this description. Ventilation with discretion is one of the most important features in the successful cultivation of orchids, and cannot be too carefully considered. The avoiding of direct draughts, either from ventilators or otherwise, must be carefully guarded against.

WATER.—In the North and North-East of England we are subjected to snow and hail storms often until well into the month of May. The snow, quickly dissolving, finds its way into the rain water tanks, and it is surprising what small a quantity of snow it takes to lower the temperature of the water in the tanks. It is advisable always to test the temperature of the water before using it.

FOR ODONTOGLOSSUMS AND MASDEVALLIAS the temperature should be maintained as evenly as possible. Now that the plants are in full bloom it is desirable to have the atmosphere as free as possible from excess of moisture during the lower night conditions. Moisture, with a prolonged period of dull weather, has a similar effect on the flowers, causing brown-spotting on all segments and rendering them unsightly and useless often before they are fully expanded. We find it desirable to afford a little ventilation in the roof, on the leeward side, and use a little extra fire-heat during the night or in dull weather. The damping in the cool division should be done early in the afternoon.—H. J. CHAPMAN, Oakwood Gardens.

HARDY FRUITS.

THE RECENT SEVERE FROST has, I fear, damaged many of the early flowers of plums, cherries, pears, etc., but the later unexpanded blooms do not as yet show any sign of injury. Raspberry growths look very yellow, and the same may be said of gooseberries and currants; good, warm showers are greatly needed to help growth.

LATE-PLANTED TREES.—Examine these very carefully, especially any which may have been left to settle in the new soil. See that all the supports are strong at the base and not likely to snap during a strong wind when the trees are in full leaf. After staking and tying is complete, prick up the surface soil two inches deep to prevent it from cracking, and to allow the rain to penetrate in every part. Light mulching with manure will prove very beneficial in dry weather, and, in the absence of a mulch, keep the soil loose by the use of the hoe.

STRAWBERRIES. — Plants which have been forced and duly hardened, may be planted out at once on well-prepared land. First see that the roots are thoroughly soaked with water, then remove a few of the older leaves, turn the plants out of the pots, slightly disentangle the roots with a pointed stick, and plant firmly 2ft. apart, a little more or less, according to the nature and condition of the soil. Keep the land free from weeds, and the soil between the plants hoed at intervals. Our first crop outside is taken from healthy young plants, grown on a warm, sheltered border in front of a long range of glass houses, and raised expressly for the purpose. Later crops are on a well-prepared plot in the open, the earliest being Royal Sovereign, and the latest Laxton's Latest and Givon's Late Prolific. Keep a careful watch for frosty nights, and protect the blooms with a handful of strawy material.

NETS.—Examine the stock of nets required for protecting all kinds of fruits, and order the quantity required. It is a capital plan to run a row of wire-netting round the outside of beds of strawberries, raspberries, gooseberries, etc., 3ft. or more high, and of 1in. mesh. The framework on which to rest the nets should be sufficiently high to allow a man to gather the fruits without having to remove the nets.

INSECT PESTS.—Keep a careful lookout for insect pests troublesome to early growths of peaches and cherries, and dust the affected parts with a little tobacco powder if the fruits are not sufficiently advanced to be safely syringed with quassia extract or other approved insecticide. Remove any blistered leaves, and have them burnt, and, if the trees have been heavily protected, lessen the protection by degrees before finally dispensing with it.—H. MARKHAM, Wrotham Park Gardens.

THE FLOWER GARDEN.

PERPETUAL CARNATIONS. — The young plants must be given plenty of room, and abundance of air when the weather is favourable. Shift them into larger pots before the roots become pot-bound, and attend to stopping at the proper time. The method of growing tree carnations by planting them out is rapidly gaining favour. Where the houses are suitable for this purpose it is to be recommended, as flowers of much more substance can be produced by this method than from plants in pots. Neither are the plants likely to suffer so much from irregularities in watering. Old flowering plants must be given plenty of stimulants now, or the flowers will be weak and of poor colour. Towards the end of the month they may be placed outdoors in a sheltered position, plunging the pots in ashes. If they are kept well supplied with water they will flower during the greater part of the summer.

MALMAISON CARNATIONS are now developing their flower spikes, and, with increased light and sunshine, they must be watered more frequently than hitherto. Remove all side buds, and secure all the flower spikes to neat stakes. Lightly fumigate occasionally as a safeguard against aphis.

CINERARIAS.—A sowing may be made now for the earliest batch of plants. Sow the seeds thinly in shallow pans in a light compost. Place them in heat and keep shaded until the seedlings are through, then place them on a shelf near the glass in a moderate temperature. Prick them off singly in small pots when large enough, and when established place them in cold frames where they can remain till late autumn. Greenfly is a persistent enemy of the cineraria, but this can easily be kept in check by lightly

fumigating occasionally with a nicotine compound.

BALSAMS.—These are most useful plants for the conservatory, and deserve more extended cultivation for this purpose. Seeds may be sown now in pans in fine, light soil. When the seedlings are through keep them growing until they are in their flowering pots. Do not stop the leading growth, and when finally potting the plants keep them as low in the pots as possible.

LUCULIA GRATISSIMA.—This is one of the most desirable of all the greenhouse evergreen shrubs, but to grow it successfully it should be planted out in the coolest part of the greenhouse or conservatory. A compost of loam, peat, leaf-soil, charcoal, and sand suits it well. The plants will now be growing freely, and should be encouraged by spraying with rain water twice daily. Plenty of water must also be given to established plants during the growing season.—E. Harriss, Lockinge Park Gardens.

THE KITCHEN GARDEN.

FRENCH BEANS. — A sowing may be made on a warm, sheltered border. The land should be pointed over with a fork before sowing, and should work freely when drawing the drills. Allow the stronger-growing varieties 2ft. 6in. between the rows, and 6in. from plant to plant. Sow in double lines, cover the seed two to three inches deep, and, when the plants are well above the ground, thin out to the above distance. The spare plants may be used for filling up gaps. For the earlier sowing Ne Plus Ultra is an excellent variety; Magnum Bonum and a good type of Canadian Wonder are most suitable for the main crop. To keep up the supply it will be necessary to make a further sowing in cold pits or frames. Earlier-sown batches of plants should be treated generously in the way of feeding, syringing, watering, etc.

SCARLET RUNNER BEANS.—The first sowing outdoors can be made in trenches previously prepared. It is well to remember that the scarlet runner is a gross feeder, and requires a considerable amount of moisture when in full growth and bearing freely. Sow the seeds in double lines; allow seven inches from bean to bean, and the same distance between the lines. Cover with soil to a depth of three inches. Where slugs are troublesome, place a small ridge of finely-sifted cinder ashes on either side of the rows. Another sowing should be made about the middle of the month, and again a fortnight later, according to circumstances. In cold localities the first sowing should be in boxes. The variety I most favour is Prizewinner.

BEET.—The main crop should now be sown whenever the ground is in a suitable condition for the purpose. Ground previously occupied by celery and trenched over as soon as the celery is cleared off is most suitable for beet. Previous to sowing, apply a good dressing of soot, which should be well raked in. Draw the drills 18in. apart and 1½in. deep; sow three or four seeds together in patches 1ft. apart, and when the young plants are well above ground thin each patch to a single plant.

BROAD BEANS.—For late use the broad or Windsor bean is much to be preferred to the long-podded kinds, more particularly the improved green varieties. On light soils it is advisable to sow in well-prepared trenches. A good mulch of short grass from the mowing machine will prevent too rapid evaporation of moisture during a spell of drought.

CLEANING THE LAND.—Whenever the condition of the soil permits, let the hoe be kept in constant use, in order to aerate the soil, and kill the weeds amongst growing crops, this work being chiefly carried out with the Dutch hoe. The onion crop should be taken in hand at an early date, and if the plants are doing well, a preliminary thinning out should take place. The old brassica stumps should be removed as soon as the heads are cut, and the land be prepared for other crops.—W. Messenger, Woolverstone Park Gardens.

NOTES FROM SCOTLAND.

Replying to the Editor's request (page 272) for information respecting the effects of the recent cold weather upon vegetation, I may say that in Scotland, owing to the protracted character of the season and the consequent backwardness of vegetation in general, and fruit blossom in particular, very little harm has been done.

Snow fell heavily on April 11 over the greater part of the country, lying several inches in depth for several hours afterwards in some places, though a still greater amount disappeared as it fell, thus lessening very considerably what would have been a very uncommon depth for so late in the season. Slight frost was at the same time experienced in very bleak, exposed situations, but, taken over a wide area, including the lower-lying and more temperate parts, this was negligible in amount. Apart, however, from this the temperature for about the space of twenty-four hours was but slightly above the freezing point, which, together with the falling snow, and continuously overcast condition of the sky, made the general aspect cheerless in the extreme.

Continual low temperature, with occasional sharp frosts, lack of sun, and a rainfall above the average, have combined to retard activity. To the same causes must be ascribed the backward state of garden operations, especially seed sowing and the planting of various crops, the accomplishment of which has been postponed from time to time, thus hampering the endeavours of cultivators very considerably.

From where these notes are penned—a village set upon a low hill side—the view extends over a long and beautiful valley, having a large area of alluvial soil, through which a swiftly-flowing stream threads its way by rock-bound channels and amid copse and woodlands which add their quota of effectiveness to the verdant slopes. This stream often overflows its boundaries during the winter season, and the waters spread far over the adjacent level tracts that for the time being are turned into miniature lakes, which last but a short time.

Beyond this plain rises in solemn grandeur a lofty, rocky plateau crowned along its edge by numerous peaks, which, I am able to state from daily observance, have never been clear of snow since January 5, when the heaviest snowfall of the season occurred. Sometimes the whole range of hills is covered, at others the snow may dwindle away until its presence is alone discernible on the higher peaks or in the numerous depressions or defiles.

This barrier of rock forms the north-eastern edge of the romantic district known in the days of King Robert the Bruce as the Forest of Buchan, then a densely-wooded sporting area. Now the greater part of the site of the forest is devoid of trees, but provides excellent pasturage for sheep. Exception to this must, however, be taken of the higher portions, where just beyond the edge of the ridges already mentioned is situated the wild desolate region of the loch district of the southern highlands, a rocky sterile waste extending for about twenty miles from Loch Enoch in the north to Loch Dee at the southern end.

This district remains unvisited in the winter season, when mists of great density often prevail, and cold, strong currents of air rise with such suddenness that the wayfarer must grasp the nearest object for support, which perforce must be something in the nature of icy rock. In summer venturesome spirits, intent upon the study of Nature or archæology, frequently make pilgrimages thither, and doubtless feel amply rewarded. Nature here remains in much the same state as prevailed thousands of years ago, but the whole lowland portion of the country has, by the agency of man, been transformed from waste to productiveness, from almost desolation to scenes of wondrous beauty and prosperity.

Dalry, Galloway. James Day.

APRIL WEATHER AT LEONARDSLEE.

The frost of April 13 will be remembered for a long time by those who have a collection of half-hardy plants and shrubs. We registered 13 deg. of frost on the grass and 7 deg. in the screen, which is very terrible to plants in a flowering stage. The earlier rhododendrons of the Thomsoni and arboreum section were very badly crippled, and the flowers practically spoilt for the season, while the hybrids were badly cut up, though fortunately the Aucklandi section has been spared. The later batch of R. ciliatum was badly injured. The frost that we experienced about a month previously cut the early blooms of these species, but sufficient were left to provide a good display, and these were in perfection on April 13.

The main crop varieties of plums that had fully expanded flowers also suffered severely, and the earliest cherries and pears were touched, though these have plenty of bloom left for a heavy crop. The amazing part of it all is that spiræas and dielytras were practically unharmed.

Everything is now very late, and what at one time promised to be a very early season has now developed into a late one. The frost did considerable damage to the better kinds of narcissus. The best batch of White Queen we have ever had was ruined.

The temperature for the season has been exceptionally low, the sun appearing but seldom, and there was rain practically every day until April 20, when we had a glorious day—quite the best of the season.

We have the rare Ranunculus insignis in bloom; we also had R. Ingalli, but it has, unfortunately, succumbed. Many rare primulas are now in flower, and such saxifrages as S. glacialis, S. Clibrani, S. Bertoloneæ, S. Bathonensis, and S. Griesbachi, with the rare Androsace pyrenaica, and there are crowds of other pretty things in the Alpine Garden. W. A. Cook.

Leonardslee Gardens.

SPIRÆA OPULIFOLIA AUREA.

The different hardy shrubs remarkable for the golden colour of their foliage may be divided into two distinct classes—firstly, those that are at their best in the spring, and gradually become greener, and, secondly, those that are at their best under the full influence of the summer's sun.

Spiræa opulifolia aurea belongs to the first class, and just as the tender leaves are nearly unfolded it is particularly attractive, as at a little distance the branches appear to be thickly studded with soft yellow blossoms. It is less vigorous than S. opulifolia itself, and, from a flowering standpoint, not the equal of many other species, but as a foliage shrub it is very pretty.

Examples of golden-leaved shrubs that deepen in colour as the season advances are Cornus Späthi and Weigela Looymansi aurea. T.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

The Hall at Vincent Square, Westminster, was well filled on April 29, but the exhibition as a whole fell a trifle short of some recent ones in point of beauty and interest. Daffodils showed that the end of their season had arrived, orchids had an "off" time, but hardy flowers, especially alpines, were abundant, and carnations were good. The National Auricula Society held their annual exhibition on this occasion, and occupied considerable space with fascinating plants and flowers.

PLANTS.

Very beautiful were the climbing roses and the bunches of cut blooms of hybrid tea and tea varieties set up in some quantity and attractively by Messrs. B. Cant and Sons, Colchester. Mr. E. J. Hicks, Hurst, Berks, presented roses also, while Messrs. Wm. Cutbush and Son, Highgate, had splendid pot roses, a beautiful lot of carnations, and some hardy flowers. Wichuriana roses staged by Messrs. Hobbies, Lim., Dereham, filled a large space, and made a bold exhibit. The weeping standards were the leading feature, and in this form Hiawatha, Mrs. L. Dewhurst, Minnehaha, Dorothy Perkins, Lady Gay, and Excelsa were the leading varieties. Mr. W. Profittlich, Twickenham, submitted the neat double deep red polyantha rose named Erna Terchendorff, a sport from Mrs. Norbet Levavasseur; this gained an A.M., and should prove a good bedding variety, as we noted it keeps its colour finely out of doors, and flowers abundantly.

Messrs. R. Gill and Sons, Falmouth, again showed brilliant Himalayan rhododendrons, including the pendulous, tubular R. Keysi. Flowering trees and shrubs from Messrs. J. Cheal and Sons, Crawley, made up a nice bank, and comprised Spiræa arguta multiflora, a cloud of white blossoms, the blue Veronica Hulkeana, wistarias, Piptanthus nepalensis, Laburnum Vossi, the neat little Abies Hookeriana, good for a rock garden, the rare Pinus Balfouriana, and the weeping and novel Cupressus arizonica.

The Guildford Hardy Plant Company and Mr. A. Hemsley, Crawley, were exhibitors of alpines; Messrs. Whitelegge and Page, Chislehurst, staged Primula Veitchi, alpine phloxes, aubrietias, saxifrages, and Viola gracilis lutea in round baskets. Messrs. Thompson and Charman, Adam Street, Adelphi, were small exhibitors of alpines, but Mr. Jas. Box, Lindfield, Haywards Heath, had a fairly large exhibit of alpine auriculas, hardy primulas, phloxes, violas, and other lovely early spring flowers; while near by The Burton Hardy Plant Nurseries, Christchurch, put up a little rock garden display, and Messrs. Reamsbottom and Co., Geashill, King's Co., staged their brilliant St. Brigid anemones.

The boldest and prettiest rock garden in the Hall was the one arranged near the gallery steps by Messrs. J. Piper and Son, Barnes. Double white cherries and bamboos formed a background, white azaleas, cytisus, and Daphne cneorum were placed on top of the rock masses; while Gentiana acaulis, Androsace sarmentosa, A. villosa, saxifrages, Cheiranthus Allioni, and Houstania cærulea nestled in colonies among the rocks. In the centre boggy area Primula japonica, P. Veitchi, and P. sikkimensis were grouped boldly. Aubrietias in variety were submitted by the Wargrave Plant Farm, The Arcade, Liverpool Street, E.C.; and alpine plants of many kinds were presented by Messrs. R. Tucker and Sons, Gray Street, Oxford; while Messrs. Phillips and Taylor, Bracknell, showed hardy primulas and saxifrages.

A bright rock garden exhibit from Messrs. T. S. Ware, Lim., Feltham, contained a selection of aubrietias and a lovely lot of the neat double form of Anemone nemorosa. Among hardy shrubs of many kinds, Mr. L. R. Russell staged Clianthus paniceus with a cluster of its lobster-clawed flowers, and some flowering plants of the elegant Lonicera Maacki. A host of saxifrages was staged in mossy baskets and in boxes by Mrs. Lloyd Edwards, Bryn Oerog, Llangollen; Oculata rosea, Pearl, Sir F. Crisp (white), Coronation, Patty, and Mrs. Lloyd Edwards were a few of the finest varieties. The lovely Gentiana acaulis and the bright Saxifraga Bathonensis were shown in quantity in a rock garden arrangement from Mr. Clarence Elliott, Stevenage. Messrs. G. and A. Clarke, Dover, filled a little rock garden with gay spring flowers, and Messrs. W. Fells and Son, Hitchin, brought saxifrages and primulas in quantity, and massed these among rocks.

Primulas from Messrs. J. Veitch and Sons, Chelsea, were very beautiful, and included P. pulverulenta, P. p. Mrs. Berkeley, a pretty blush tint with orange eye; the free-flowering P. Veitchi, P. Unique, P. sibirica chinensis, and P. longutica with crimson-carmine flowers. Meconopsis integrifolia was present with its yellow blooms, and near by was a rare display of nemesias in brilliant colouring, and also in purest white. Messrs. Barr and Sons contributed a rock garden exhibit, and in this the beautiful Iris pavonia was very charming. Messrs. G. Bunyard and Co., Maidstone, had a nice selection of the varieties of Iris pumila, of saxifrages, aubrietias, and tulips. Scilla campanulata in various colours, a lovely batch of Daphne cneorum, Primula Forresti, Androsace Chumbyi, and a host of other lovely things were set up in a rock garden by Mr. Maurice Prichard, Christchurch. Messrs. G. Jackman and Son, Woking, had Iris pumila cyanea, deep blue, among other alpines, etc. Messrs. Bakers, Wolverhampton, made a feature of Ranuneulus amplexicaule and the gay, dwarf Saxifraga Codsall Gem.

Mr. P. Ladds, Swanley, had a miscellaneous contribution, wherein Hydrangea Mdme. Emile Moulliere was superbly shown, the superb heads carrying enormous white-fringed flowers. Lovely shades of rose, salmon, and of maroon were seen in the hippeastrums exhibited by Messrs. R. P. Ker and Sons, Liverpool, and varieties of great excellence representing these colours were Rose Gem, Hesperus, and Midnight. A mixed group from Messrs. Stuart Low and Co., Enfield, contained blue hydrangeas, beautiful acacias, and gerberas.

The chief new things were a dwarf daphne-like plant with clusters of pink flowers, named Ætheonema armenum Warley Hybrid (A.M.), from Miss Willmott, V.M.H., Great Warley; Primula La Lorraine (A.M.), with purplish flowers, from Mr. M. Prichard, a hybrid between P. Veitchi and P. cortusoides; and Wallflower Primrose Monarch, with large, soft yellow flowers in dense spikes, from Mr. Moss, Kelvedon.

Dobbies' Perfection strain of calceolarias made up a bold and brilliant group, and the plants revealed an unusually wide range of colours; these were from Messrs. Dobbie and Co., Edinburgh. This firm also showed long-spurred columbines, and three dozen pans of violas that were very pretty early in the day, but by the middle of the afternoon the great heat made many of the flowers hang their heads. Violas and pansies from Messrs. Carter Page and Co., London Wall, were very effective, set up in pans, and their fragrance was delightful. Mary Allwood, White Wonder, and Mrs. C. W. Ward were the carnations Messrs. Allwood Brothers set up finely. Mr. H. Burnett, Guernsey, had carnations in grand form, and set up glorious bunches of grand flowers.

We may refer to Messrs. Wills and Segar, of Kensington, who had golden arum lilies and blue hydrangeas among other strong plants; to Mr. G. Reuthe, Keston, whose rhododendrons were vastly interesting and beautiful; to Messrs. H. B. May and Sons, Edmonton, who brought up fragrant gardenias, sweet violas, and ferns; to Messrs. H. Cannell and Sons, Swanley, and Mr. H. J. Jones, Lewisham, both of whom displayed zonal pelargoniums in fine style, and provided rare masses of vivid colouring; and to Messrs. W. Wells and Co., Merstham, who contributed a small set of carnations.

NARCISSI AND TULIPS.

The Narcissus and Tulip Committee has had a fairly strenuous season, and on this occasion there were a number of good groups, as well as many varieties up for awards.

A garden of tulips and daffodils was charmingly arranged by Messrs. J. Carter and Co., the former placed in a long bed bordered by grass; higher up, on a rock-supported terrace, such daffodils as Dairymaid, Gloria Mundi, Vanilla, Aspasia, King Alfred, Argent, and the lovely White Lady were massed in groups in front of conifers, Japanese maples, and magnolias. A fine lot of daffodils from Messrs. R. H. Bath, Lim., Wisbech, contained really fine flowers of Epic, Laureate, Maggie May, Refulgence, Cygnet, Princess Ena—a fine triandrus hybrid, Larissa, and the glowing Will Scarlet.

Mr. W. B. Cranfield, Enfield Chase, showed a lovely strong-growing triandrus hybrid named Venetia (A.M.), and Mr. H. Phillips secured an A.M. for Evangeline, a Leedsi variety already fairly well known.

Some splendid Darwin and May-flowering tulips were set up in big bunches in bowls and vases by Messrs. R. and G. Cuthbert, Southgate. The blooms were finely grown, and only needed something for a groundwork to display them to full advantage. Bartigon, Feu Ardente, Louis XVI., MacMahon, Loveliness, Bacchus, Duke of Westminster, La Tulip Noir, Union Jack, and Pride of Haarlem, were all grand varieties. Messrs. Sutton and Sons, Reading, set up daffodils in quantity, and showed large masses of Persian Orange, Sidney, Mdme. de Graaff, Evangeline, Stonechat, Incognita, Ptarmigan, and Weardale Perfection.

Messrs. Barr and Sons, Covent Garden, had a bold exhibit of daffodils and tulips, the former very good for this late date; Glitter, Will Scarlet, and Royal Star were strikingly good, and there were a number of new seedlings, one, something like Seville, attracting most attention. Messrs. Cartwright and Goodwin, Kidderminster, presented very fresh flowers of daffodils, and set up goodly bunches of Epic, a good poet: the lovely Rigoletto, Heroine, Cavalier, with rich orange centre; the bold Will Scarlet, and equally startling Seville, the chaste Evangeline, etc. Messrs. Jas. Veitch and Sons, Chelsea, also exhibited daffodils, and presented poetaz varieties well.

The Rev. G. H. Engleheart, Dinton, staged very beautiful new unnamed daffodils, largely poeticus varieties or Barri forms with solid white perianth segments. Some of the flowers had a delightfully cool appearance, and there were two seedlings with cream-tinted crowns, and with a wonderful green shade in the centre, and which seemed to have a great deal of blue in it as one looked steadily at the flower for several seconds. This was a fine display of lovely late flowers.

ORCHIDS.

Orchids were a small part of the exhibition, but of great merit and importance was Odontoglossum amabile Zeus (A.M.), pure white ground with rosy-crimson blotches and spots over the central part of the sepals and petals. This, together with fine specimens of Cattleya Prince Olaf, Westonbirt var., six grand flowers; Cattleya Enid, Westonbirt var., with six brilliant purple-lipped blooms; and Cattleya Schröderæ Luna, with three lovely blush-tinted flowers, came from Sir G. Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury.

H. S. Goodson, Esq. (gardener, Mr. G. Day), Putney, sent fine examples of Odontoglossum illustre var. Radium, and O. Helen Lemeux, Goodson's var., a glorified Wilckeanum. Sir Trevor Lawrence (grower, Mr. W. White), Burford Lodge, Dorking, presented

white-lipped, green-petalled Epidendrum [illegible], carrying six large, semi-drooping [illegible]—a cultural commendation was [illegible].

Messrs. J. Cypher and Sons, Cheltenham, had a bright display of golden dendrobiums and [illegible], with Miltonias, masdevallias, and odontoglossums. Mr. A. W. Jensen, Lindfield, presented a very pretty group of well-grown light forms of Odontoglossum [illegible], with Cattleya Mendeli. Messrs. [illegible] and Co., Southgate, had excellent [illegible] of Cattleya Schröderæ and C. Mendeli, with a central group of the bright [illegible] yellow Lælio-cattleya G. S. Ball. Mr. [illegible] Waters, Balcombe, Sussex, exhibited [illegible] in variety, with Cattleya [illegible], C. Mendeli, and Lycaste Skinneri.

FRUIT AND VEGETABLES.

Vegetables were capitally shown by Messrs. Jas. Carter and Co., Raynes Park, the exhibit being greatly admired, both for the arrangement and the high culture evidenced in every specimen; Ideal cucumbers, Florence Fennel, Chicory, Moore's Cream vegetable marrows, radishes, long turnips, Mammoth spring white broccoli, and sea-kale were made special note of.

AWARDS OF MERIT.

No First-class Certificate was awarded on this date.

Award of Merit.—To Primula La Lorraine, from Mr. Maurice Prichard, Christchurch; to Rhodocoma armenum Warley Hybrid, from Miss E. Willmott, V.M.H., Warley Place, Great Warley; to Wallflower Primrose Monarch, from Mr. Moss, Kelvedon; to Rose Frau Teschendorff, from Mr. W. Profittlich, Cockenham; to Narcissus Evangeline, from Mr. H. Phillips, Olton; to Narcissus Venetia, from Mr W. B. Cranfield, Enfield Chase; and to Odontoglossum amabile, var. Zeus, from Mr. George Holford, Westonbirt, Tetbury, Gloucester.

MEDALS.

Silver-gilt Flora.—To Messrs. Hobbies, Ltd., Dereham, for roses.

Silver-gilt Banksian.—To Messrs. Barr and Sons, Covent Garden, for daffodils; to Messrs. R. and G. Cuthbert, Southgate, for Darwin tulips.

Silver Flora.—To Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. H. Bath, Lim., Wisbech, for daffodils; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. B. R. Cant and Sons, Colchester, for roses; to Messrs. J. Carter and Co., Raynes Park, for a spring garden of daffodils and tulips; to Messrs. W. Cutbush and Son, Highgate, for carnations, roses, etc.; and to Messrs. J. Piper and Son, Barnes, for rock garden.

Silver Banksian. — To Messrs. Allwood Brothers, Haywards Heath, for carnations; to Messrs. J. Cheal and Sons, Crawley, for flowering shrubs, etc.; to Messrs. Dobbie and Co., Edinburgh, for calceolarias and violas; to Mr. H. J. Jones, Lewisham, for pelargoniums; to Messrs. R. P. Ker and Sons, Aigburth, Liverpool, for hippeastrums; to Messrs. H. B. May and Sons, Edmonton, for gardenias, etc.; to Messrs. Carter Page and Co., London Wall, for violas; to Messrs. Phillips and Taylor, Bracknell, for auriculas; to Mr. M. Prichard, Christchurch, for hardy flowers; to Mr. L. R. Russell, Richmond, for shrubs, etc.; to Messrs. Jas. Veitch and Sons, Chelsea, for flowering plants; to Messrs. T. S. Ware, Lim., Feltham, for rock garden; to Messrs. Wills and Segar, Kensington, for greenhouse plants; to Messrs. Sutton and Sons, Reading, for daffodils; to Messrs. Cartwright and Goodwin, Kidderminster, for daffodils; to Mr. C. F. Waters, Balcombe, for orchids; to Mr. A. W. Jensen, Lindfield, for orchids; and to Messrs. Hassall and Co., Southgate, for orchids.

Bronze Flora.—To Mr. J. Box, Lindfield, for hardy flowers; to Messrs. Stuart Low and Co., Enfield, for greenhouse plants; and to Messrs. W. Wells and Co., Merstham, for carnations.

Bronze Banksian.—To Mrs. Lloyd Edwards, Llangollen, for saxifragas; to Mr. Clarence Elliott, Stevenage, for alpines; and to Mr. Phillip Ladds, Swanley, for hydrangeas, etc.

NOTICE.

who will give the matter immediate attention.

National Auricula and Primula Society.

Despite an untoward season, the auricula growers and fanciers were able to bring forward a capital display of both show and alpine auriculas. There was a very fair competition, and the quality of self flowers and alpines seemed to be of a high order, while polyanthuses were very gay.

For twelve auriculas, dissimilar, there were four entries, Mr. Jas. Douglas, Great Bookham, leading with a beautiful twelve. The best varieties were Rifleman, Mikado, Shirley Hibberd, Harrison Weir, Guy Cranfield, Marmion, Sunray, and Flame, a splendid ruby-crimson flower with broad-banded petals, and delightful paste. Messrs. Phillips and Taylor, Bracknell, Berks, came second with fine examples of Mrs. Potts, Mrs. Barnett, Abraham Barker, Harrison Weir, and George Rudd. Mr. W. M. Shipman, Altrincham, was third with nice plants of Favourite, Shirley Hibberd, Olympus, and Molly Shipman; Mr. J. Gibson, Belmont, Surrey, was fourth.

There was a similar number of entries for six varieties, distinct, Mr. Jas. Douglas winning the first prize with some superb specimens, which were William Smith, a fine green edge, Queen of Spain, Harrison Weir, Shirley Hibberd, Marmion—grand, and Acme. Messrs. Phillips and Taylor came second, having fine plants of Mrs. Henwood, Richard Headley, and Rachel; Mr. W. M. Shipman was third; and Mr. J. L. Gibson fourth. For four varieties, distinct, there were six entries, Mr. W. B. Cranfield winning first prize with a good level lot. The best were Mrs. Henwood, Harrison Weir, and Miss Prim; Mr. F. W. Price, Beckenham, was a capital second with Mrs. Henwood and Olympus; while Messrs. A. S. Hampton, Reading, and Mr. H. W. Miller, Birmingham, brought up the rear in the order stated.

The competition for two varieties appeared to be popular, judging by the number of entries. Mr. F. W. Price was the first prize-winner, staging fine plants of Mrs. Henwood and Olympus. Mr. W. B. Cranfield, Enfield Chase, came second with a nice plant of Sunshine; Mr. H. W. Miller was third; and Mr. A. S. Hampton fourth.

There were quite an array of plants for a single specimen of a green-edged variety. Here Messrs. Phillips and Taylor, Bracknell, proved the victor with a well-developed specimen of Mrs. Henwood. The same exhibitors captured the second prize; while Mr. Shipman was third with a beautiful plant of Miss Ethel. For a single grey-edged variety Mr. Jas. Douglas was first with Marmion, and second with the same variety; while Mr. R. Cranfield was third with Geo. Lightbody; there were eleven entries. The white-edged varieties were represented by six entries, Mr. Jas. Douglas leading with Acme. The second-prize plant was Conservative, but the owner's name was not on the card; while Mr. Douglas was third with Rachel.

The self varieties did not make the show one would have thought. Mr. Douglas won first prize with Harrison Weir, and second with Mrs. Phillips. The third position was awarded Mr. J. G. Bennett with a fine plant of Mikado. Class 9 was for new seedlings, Mr. Shipman winning first prize with a green-edged variety. He was also first in the grey-edged seedlings; while Mr. G. Langlands was the victor in the selfs, but, as all were unnamed, they were of little interest to the public.

The novices' classes for four varieties only brought out two competitors, Mr. W. Nash, Epsom, securing the first prize with a nice level exhibit; while Mr. H. W. Miller, Birmingham, was second. The class for those amateurs who do not employ a gardener secured four entries. Mr. A. S. Hampton won first prize; Mr. H. W. Miller was second, and Mr. J. L. Gibson third.

In the class for twenty-four alpine varieties, not less than twelve, dissimilar, Mr. Jas. Douglas won the first prize with a superb display. The colours were intensely rich. The chief varieties were Mrs. Jas. Douglas, Argus, Phyllis Douglas, Prime Minister, Robert Bruce, Golden Dustman, Vincent, Blue Jay, and King George. Messrs. Phillips and Taylor, Bracknell, followed, having Myrtle, Triumph, Argus, Antarctic, and Sunbeam in fine form; Mr. W. M. Shipman was third.

There were four contestants for twelve varieties, Mr. Jas. Douglas still leading with splendid examples of Majestic, Golden Dustman, Phyllis Douglas, and Dazzle. Messrs. Phillips and Taylor were a capital second with Mars, Antonio, and The Queen as the leading varieties; Mr. J. L. Gibson was third. The class for six alpines evidently suited the amateurs, for there were seven entrants. The first prize was awarded Mr. F. M. Price, who had excellent examples of Majestic, Mrs. Jas. Douglas, Claud Halero, and Argus. Mr. Robert Morton, Woodside Park, was second, and Mr. H. W. Miller third.

In the remaining classes, Messrs. F. W. Price, W. B. Cranfield, W. F. Chappell, H. W. Miller, J. Dupuy, and J. L. Gibson were the chief prizewinners, and the chief varieties staged were Phyllis Douglas, Mrs. Jas. Douglas, Argus, Mrs. Berkeley, and Bluebell.

For twelve fancy varieties there were but two competitors, Mr. Jas. Douglas having a long lead for first place with an admirable variety of colours. The most conspicuous varieties being Mrs. Gardiner, Kate Nickleby, Dorothy Cutts, Sunrise, Lady H. Veitch, and Old Gold. Mr. J. L. Gibson was second. Messrs. Phillips and Taylor were the only exhibitors of a group of primulas and auriculas, and they were deservedly awarded the first prize, for the group contained some fine examples of P. japonica, P. Sieboldi, P. Farinosa, P. rosea, and P. nivalis; while the auriculas included some choice fancy and alpine varieties.

Mr. S. Mortimer, Farnham, was the only competitor for twelve polyanthus in pots, and he had a splendid strain that gained the first prize. There were two groups of primroses or polyanthus. Mrs. Milner, Totley Hall, Sheffield, being awarded first prize for a very bright collection, the crimsons and yellows being especially good. Mr. S. Mortimer was second with a fine strain though the crimsons were somewhat sunburnt; the yellows were wonderfully rich.

Mr. Chas. Turner, Royal Nurseries, Slough, staged a fine table of auriculas, which embraced the show and alpine varieties, a number of the latter being arranged in separate colours; also two baskets of gold-laced polyanthus which were much admired. From Mr. J. Crook, Camberley, Surrey, came a fine collection of polyanthus in a fine range of colours, some of the lighter shades being unique.

Messrs. Jas. Veitch and Sons, Lim., Chelsea, had an extensive exhibit of show and alpine auriculas in great variety, the alpines

being especially good, and the groundwork of adiantum added to the beauty of the flowers, the yellow varieties being especially fine; while Messrs. Phillips and Taylor, Bracknell, staged a good collection of auriculas, the green-edged variety, Mrs. Henwood, being very fine, as were also the alpine varieties. Messrs. B. Ladhams, Lim., The Shirley Nurseries, Southampton, also had a fine exhibit of crimson polyanthus arranged in a basket.

Scottish Horticultural Association.

On April 26, on the invitation of Mr. C. W. Cowan, over 100 of the members of this association visited Dalhousie Castle, in order to see the magnificent collection of daffodils which has been brought together there. The collection is the most extensive in Scotland, if not in Britain, and it contains all the finest of the most recent varieties. There were also noticed some very fine seedling varieties raised by Mr. Pirie, Mr. Cowan's gardener. A great deal has been done in the way of naturalising some of the kinds, and the great masses of trumpet varieties like Emperor, Empress, Glory of Leiden, etc., on the grass slopes beneath the Castle, where they have thoroughly established themselves, were much admired. Primroses and many other plants are also being extensively naturalised, and in the garden proper there is a large and varied collection of herbaceous plants. The party were entertained to tea in the Castle by Mr. and Miss Cowan, and on the call of the President, Mr. King, they were accorded a very hearty vote of thanks, in acknowledging which Mr. Cowan expressed the pleasure it gave him to see the members at Dalhousie. The weather was not very favourable, rain falling most of the time, but nevertheless the excursion was a most enjoyable one.

Croydon Gardeners' Society.

The recent meeting of this society was held in the lecture room of the Town Hall, Croydon. It is the good fortune of Croydon to have a splendid up-to-date collection of books in the public library, and with the idea of bringing them more to the notice of the members of the society this meeting was arranged. A very able and instructive address was given by Mr. J. Harrison Dick, who dealt with gardening works from the early periods down to the present time. As long ago as 1440 writings on garden subjects were known, and the first book written by the Abbot of Cirencester is still in existence, and the directions contained therein can be followed at the present time. Mr. Dick alluded to many useful writers in the 17th and 18th centuries, and in the several periods referred to the methods of culture they recommended. Fashions changed considerably in gardening, and the possessors of big gardens lavished small fortunes upon their ideals. Since 1820 writers have been more abundant, and now, with a cheaper literature in vogue, one can find many authors on a single subject, and there appears to be no phase of culture left untouched. With such a big collection of horticultural books as the Croydon libraries contains, it is difficult to mention each work, but where occasion required Mr. Dick brought to the notice of his audience these special works.

The Chief Librarian (Mr. Stanley Jast) and his staff of capable assistants arranged a number of the books for the members to view, and keen interest was displayed in looking through the volumes. Time would only allow just a peep at the books, but it was sufficient to enable the members to appreciate the value of the collection at their disposal for reference when occasion requires.

After tributes of appreciation to Mr. Harrison Dick for his address, and to the Libraries Committee and Mr. Jast for their kind privilege extended to the society, the meeting was brought to a conclusion.

THE DESTRUCTION OF ALBIZZIA LEBBEK IN CAIRO.

Mr. G. St. C. Feilden, Chief Gardener to the City of Cairo, has, at the request of the Kew authorities, contributed to the current issue of the "Kew Bulletin" the following notes on the mealy bug which has caused such havoc among the Lebbek trees in the streets of Cairo.

Until the summer of the year 1909 Cairo contained some thousands of fine specimens of Albizzia Lebbek, which formed shady avenues throughout the town. In the space of four years three-quarters of these trees have disappeared, their destruction having been brought about by the ravages of a species of mealy bug, Dactylopius perniciosus. Such are the depredations of this pest that in four months it will entirely destroy the largest tree. Although it is only in recent years that this mealy bug has made its presence felt it has doubtless existed in Egypt unnoticed for a number of years.

The insects can be found on almost every Lebbek in the neighbourhood of Cairo, but it is only in the town itself that it has caused serious damage. Here the trees planted in paved and tarred streets, deprived of air at the roots except that provided by a small grating, and shut in by high houses on each side, were growing under unnatural conditions and were in consequence in indifferent health. On the Gesireh side of the Nile, where the paths are not paved or the roads tarred, and where the trees are exposed to very wind, the mealy bug, though everywhere present, makes no headway. It would seem therefore that the increase of the insect is influenced by the state of the health of the host. The attack begins in May, is at its height in June and July, and commences to slacken in August. The species appears to be very prolific. Mr. F. C. Willcocks, entomologist to the Khedivial Society of Agriculture, found 1,100 eggs in the ovisac of a female.

The young larvæ settle on the twigs and in the axils of the leaves, and the trees then appear to be covered with lumps of dirty white wool. Presently the whole crown of the tree shrivels, presenting a scorched and blackened appearance. The leaves then fall but many are caught and retained by the sticky secretion of honeydew given off by the insects by their slightly adhesive ovisacs. Little bundles of fallen leaves and stamens thus accumulate all over the tree, giving it a bunched appearance. These collections of leaves form a very efficient protection to the insect and render the application of sprays or emulsions almost useless. In August the tree is completely defoliated and in a few months it dies. As above mentioned, spraying, unless carried out at an early stage, is of little avail, and furthermore the height of the trees renders the operations very difficult of thorough performance. A drastic remedy tried was that of cutting back the trees attacked almost to the main trunk and cleansing with a strong petroleum emulsion applied with a stiff brush.

The trees so treated, however, nearly always died, or if they survived were permanently spoilt in appearance. There can be no doubt that the Lebbek is doomed as an avenue tree in Cairo, except under the most favourable conditions. The problem that remains is to find the most suitable trees to take its place. The danger of relying on one species only has been sufficiently demonstrated.

Leeks.—If desirable that good specimens should be obtainable by early autumn, trenches should now be prepared much in the same way as for celery. The leek is a gross feeder, therefore a heavy dressing of well-rotted manure should be incorporated with the soil in the trench; the top six inches should consist of good soil, to which add a good dressing of wood ashes and soot. After the plants have been well hardened, lift them with a good ball of roots, and place fifteen inches apart in single lines; plant moderately firm, and water in if the soil is at all dry. The blanching process may be proceeded with in the course of a week or ten days. Brown paper collars should be used, drawing them up gradually as the leeks grow until the desired length of stem is obtained. At no time should the plants suffer from lack of moisture.—W. Messenger.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

STREPTOSOLEN (BROWALLIA) JAMESONI.—C. W. G., Manningham: I have always understood that Streptosolen Jamesoni, now so much used as a "dot plant" for summer bedding, was a comparatively new introduction; but am told now that it is a very old plant. Can you put me right in this matter?—Streptosolen Jamesoni was introduced from Columbia in 1847, and after a few years it seemed to disappear from cultivation. About thirty years ago it reappeared, and for a good while was used as a greenhouse climber or pillar plant, but it did not become really popular until some genius discovered its value for summer displays out of doors.

MANURES TO PROVIDE HUMUS.—P. L., Cheltenham: What kinds of manures are the best to use in a fairly good and well-worked soil, when it is almost impossible to secure animal manure to supply humus?—In many gardening establishments, and especially in these days of motor cars, animal manures cannot be obtained in sufficient amount for the total requirements of plant food. In such cases it is necessary to obtain as a basis for the manuring some slowly-acting nitrogenous body of an organic origin which will provide a certain amount of humus matter, such as meat-meal, fish guano, dried blood, rape dust, or shoddy. This should be dug into the ground in winter or early in spring, at the rate of 8lb. to 12lb. per square rod. With this should be applied 4lb. to 6lb. per square rod of a phosphatic manure, like steamed bone flour or phosphatic guano, also kainit at the rate of 6oz. to 8oz. per square yard, every other year or so. Finally, when the plants begin to grow a little active nitrogen, in the shape of sulphate of ammonia, nitrate of soda, or nitrate of lime, at the rate of 1½lb. to the square rod, or ½oz. in a gallon of water.

PROPAGATION OF LITHOSPERMUMS.—F. N., Salisbury: Please tell me the best time to propagate lithospermums, and the best method of securing a good stock.—The beautiful lithospermums are readily propagated from cuttings taken during July and August and inserted in sandy soil in a cold frame, and kept close until roots are formed, afterwards potting up the plants to establish, and subsequently planting in their permanent positions in spring. L. Gastoni and L. graminifolium will at times give a few good seeds, which are best sown as soon as ripe, standing the pots in a cold frame until germination takes place.

CARPETING FOR JAPANESE MAPLES.—S. M. B., Whitstable: My employer has under the ruddy and purple-leaved maples, and we have separated the varieties with red or purple leafage from those having yellow, or yellowish-green, foliage, and propose to plant each set in a separate large bed. The plants are not exactly standards, but each has a distinct stem at the base. We want to cover the ground under and between the maples with some low-growing plant that will be effective, and at the same time show up the pretty foliage of the maples. Can you suggest good subjects for this purpose?—We have seen violas used with great success under Japanese maples planted in beds or large groups. You cannot do better than plant a yellow viola under the ruddy and purple-leaved maples, and a soft blue viola under the golden and green sorts.

FAILING TOMATOES.—G. P. T., Oxon: Could you help me in respect to the enclosed tomato plants? We procured them in January, and I did not like the look of the plants then, as they were drawn. They grew fairly well in 48's, and were duly planted out in single rows on stages in a temperature of from 60 to 70 degrees by day. Along one side of the house many plants developed a blue appearance, and now some of these have withered up. The soil is in good condition, and was dressed with a soil disinfectant previous to use. The plants that remained in pots have practically all failed. I have grown tomatoes for years, but have never seen any go like these. Your help will be much appreciated.—The trouble is at the roots, these being insufficient to carry the plants now that fruiting has commenced. Possibly the seedlings were raised in great heat and abundant moisture, and have never recovered from the check received in infancy. We find no trace of disease on the foliage. Shade the plants a little during bright sunshine, allow plenty of ventilation, and water with the utmost care. Spray occasionally with a weak solution of sulphide of potassium.

NATIONAL ROSE SOCIETY.—H. T., Burton: The secretary of the National Rose Society is Mr. Edward Mawley, V.M.H., Rosebank, Berkhamstead, and the minimum annual subscription to the society is 10s. 6d. Mr. Mawley will send you all particulars upon application.

RECORD OF THE INTERNATIONAL EXHIBITION.—J. T. T., Stowmarket: While visiting the Royal International Horticultural Exhibition at Chelsea last spring, I saw some bills displayed in the grounds stating that a certain firm would publish a coloured record of the great exhibition. Please let me know whether such a record has been published, and if so, by whom and at what price?—This record has not yet been published, but we understand that the material is now in the printers' hands, and that early publication may be expected. Due notice of the appearance of this work will be given.

NAMES OF PLANTS.

AVEYARD.—Appears to be a small flower of Mdme. Abel Chatenay rose.

C. M., Colne.—1, Rehmannia angulata; 2, Boronia heterophylla; 3, Corydalis lutea; 4, a Corydalis, species not recognised; 5, Begonia semperflorens gigantea.

J. T. T., Stowmarket.—We do not undertake to name florists' flowers; however, 1 is the Campernelle Jonquil; 2, Narcissus biflorus; 3, probably Katherine Spurrell; 4, a small Barri conspicuus; 5, very like Leonie; 6, N. Nelsoni.

CATALOGUES RECEIVED.

AMOS PERRY, HARDY PLANT FARM, ENFIELD.—A happy reminder of the hardy plants suitable for spring planting, with lists of aquatics and florists' flowers.

MANSELL AND HATCHER, LIM., RAWDON, LEEDS.—A useful list of liliums, special prominence being given to the Burmese L. sulphureum and L. nepalense.

E. A. WHITE, LIM., BELTRING, PADDOCK WOOD.—A description of garden enemies and the Abol specialities and sprayers for their prevention and destruction.

LISSADEL BULB FARM, SLIGO.—An illustrated, descriptive, handy-sized, and altogether useful and interesting list of alpine and herbaceous plants, and ornamental shrubs.

NATIVE GUANO CO., 29, NEW BRIDGE STREET, BLACKFRIARS.—In this company's publication directions for the use of Native Guano are given, and there are many pages of testimonials to the value of this fertiliser.

ANT. ROOZEN AND SON, OVERVEEN, HAARLEM, HOLLAND.—A spring list of bulbs and roots for spring planting, together with lists of vegetable and flower seeds. The firm's London agents are Messrs. Mertens and Co., 3, Cross Lane, St. Mary-at-Hill, London, E.C.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, May 5.—United Horticultural Benefit and Provident Society, adjourned annual meeting at the Royal Horticultural Hall, at 8 p.m.

TUESDAY, May 6.—Forest Gate Chrysanthemum Society's meeting.
Scottish Horticultural Association.
National Amateur Gardeners' Association, monthly meeting.

THURSDAY, May 8.—North of England Horticultural Society, monthly meeting, at Leeds; lecture on "The Food of Plants."

The following dates of exhibitions have been recently announced:

Epsom Horticultural Society, Rose Show, June 26, at Woodcote Grove; Summer Show, August 4, at Epsom College.
Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.
Ealing Horticultural Society, July 9.
Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.
Ulverston Rose and Sweet Pea Show, July 18.
Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.
Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.
Tunbridge Wells Flower Show, July 23 and 24.
St. Quintin Horticultural Society, July 24, in the Gun Club grounds, Wood Lane, W.

THE GARDENERS' MAGAZINE

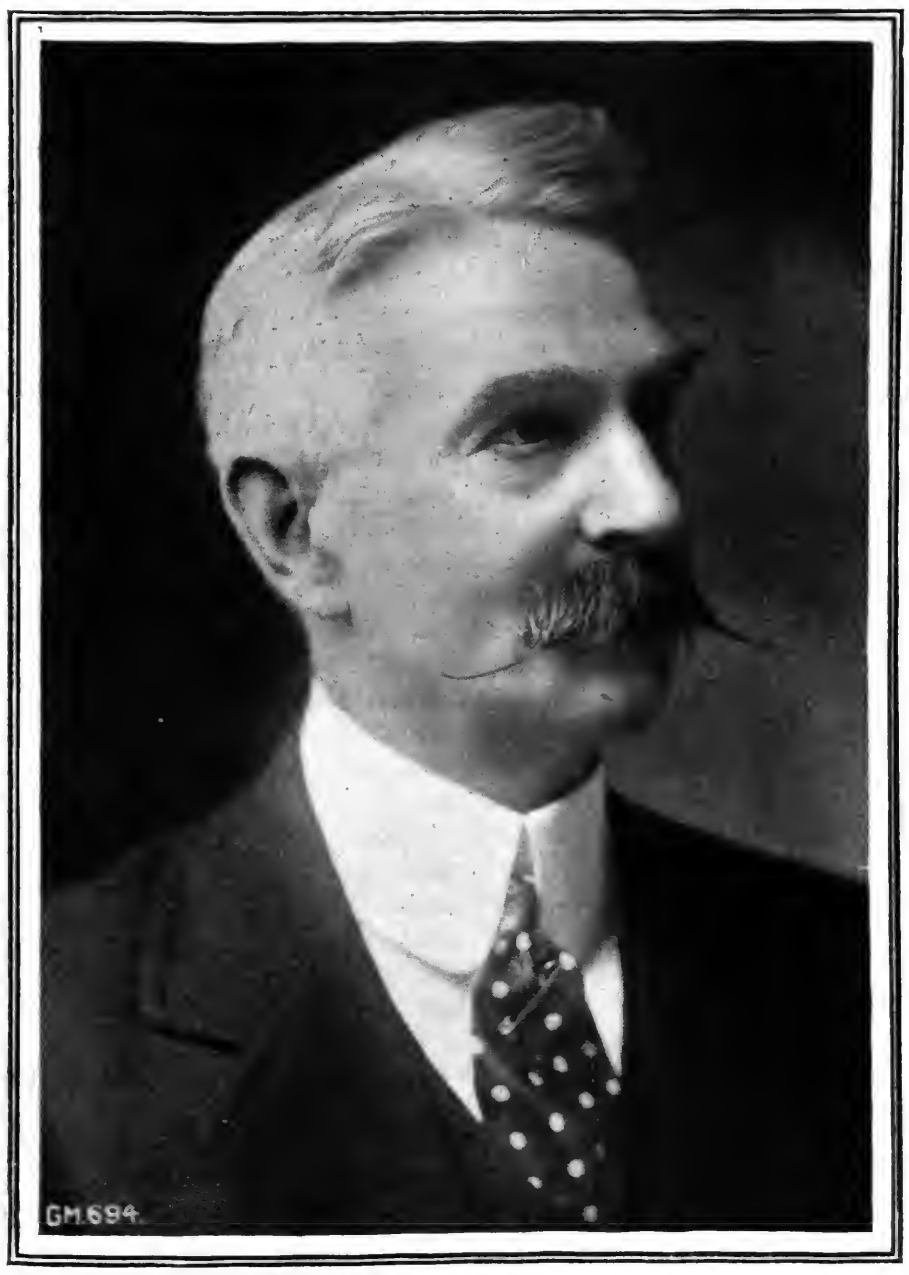
NOTE OF THE WEEK.

Tulips.

When enjoying the delightful effects produced by the play of sunlight on the glistening flowers of the various sections of tulips in their diversity of colouring, as they are gently swayed by the passing breeze, the question sometimes arises as to whether these beautiful bulbous plants are planted so freely in gardens as might with advantage be done. Instead of giving a direct answer thereto it may perhaps serve a more useful purpose to acknowledge that in many gardens, and these not always of the largest, they are taken full advantage of for the production of rich colour effects at a time when, owing to the general dulness of vegetation, high colouring is highly appreciated. Where they are liberally and judiciously planted there are continuous displays extending over a considerable period, that are not only immensely attractive in themselves, but are quite distinct from those produced by other classes of hardy plants that yield of their floral wealth during the spring season. The first of the tulips to give brightness to the flower garden are the Dutch varieties, which are a trifle formal, due chiefly to their dwarf growth, but they afford a wide range of colour, and vary sufficiently in their time of flowering to enable the planter to select varieties that will give a successional display of flowers extending over a considerable period. Then follow the Cottage, Darwin, and Rembrandt varieties for beautifying the garden, and the English show tulips which are capable of giving unbounded pleasure to those who understand and appreciate their distinctive characteristics. It should be remembered, when an endeavour is being made to properly estimate their value in the flower garden, that not only are tulips highly attractive when in bloom, but that they so readily lend themselves to artistic treatment as to admit of their being planted alone, or in association with other plants, with the most satisfactory results. They have also the advantage of being inexpensive, a point of some importance to a considerable proportion of flower lovers, the bulbs of many beautiful varieties being so cheap that there is really no occasion to trouble overmuch about keeping them for a second year. In some gardens tulips are but sparingly planted, possibly owing to the colour or form of the flowers not appealing to the taste of the owners. Not all who appreciate the charms of the flower garden are in agreement with regard to the relative merits of the various classes of plants grown therein, a fact with which the majority of our readers will be quite familiar. There is not, however, so much difference in the opinion held by cultivators as to the value of tulips for garden decoration, as that which has evidently been held by the poets on the beauty of these flowers. Churchill describes the flower as "The tulip idly glaring to the view," and states also that "The fairest tulip's not the sweetest flower." Gay writes of "The gaudy tulip's streaky red," and with reference to the effect produced in the garden, Shenstone, who was a landscape gardener of considerable eminence as well as a poet, has written,

"Distant they strike inelegantly gay,
To the near view no pleasing charms display."

In contrast to this whole-hearted condemnation of these flowers, we have Hood's statement, tnat "The tulip is a courtly queen." Miss Landon's description of the blooms as "The wine cups of the sun," and Tennyson's charming line "Deep tulips dashed with fiery dew." The tulips now at the command of cultivators vary so considerably in character and colour, that owners of gardens possessing the most divergent tastes should not have much difficulty in finding some that will afford them much gratification. If it were desirable to discuss the relative merits of the several sections in which tulips are arranged, it might be said that, from an æsthetic point of view, the Dutch varieties, of which the brilliantly coloured Keizerskroon is a well known representative, are the least desirable. It is true they lack the elegance characteristic of the May-flowering varieties, but to balance this they bloom during April, when flowers are but few, and their stiff stems prevent the flowers being buffeted about by the wind, and it may be seriously injured. If they are rather formal they are highly effective, and possess much beauty, and the section cannot be dispensed with in gardens where it is desired to have a bright display of flowers during April. As so well known to those who have given any considerable share of their attention to the May-flowering tulips, there is a considerable difference in the several sections, and of these the Cottage, Darwin, and Rembrandt varieties are the most generally useful. These should be selected according to taste, but when there is no strong predilection for either, the three sections should be grown in about equal numbers, because of the greater variety both in form and colour of the flowers that is obtained. Within recent years the flowers of the Darwins have obtained considerable popularity for decorative purposes in a cut state, and in many private gardens a considerable



MR. W. L. WALLIS,
Secretary of the East Anglian Horticultural Club.

planting of the Darwin varieties, having flowers decisive in colouring, is made in the kitchen garden for the supply of flowers for the house. The Darwins are also grown under glass in immense quantities for the flower markets, where they find a ready sale, their stiff, erect stems rendering them of much value to those who have to carry out floral decorations. The usefulness of the tulips that bloom during the present month is so great that those who are engaged in garden management should take advantage of the opportunities they may have for becoming acquainted with the numerous varieties, and the purposes for which they are best adapted.

Mr. W. L. Wallis, the secretary of the East Anglian Horticultural Club, has charge of the correspondence department of Messrs. Daniels Brothers, Norwich, a firm he has served for over thirty years. Mr. Wallis was appointed secretary of the famous East Anglian Horticultural Club at the end of 1897, when the membership was 99, and the turnover £55 10s. 11½d.; whereas now there are 365 members, and the annual turnover is about £133. Needless to say, much of the enthusiasm at Norwich is due to the energy and enterprise of Mr. Wallis, who not only inspires confidence, but creates enthusiasm, and persuades everyone to do the best for the club. He possesses an excellent capacity for organisation, and the society's outings are his special care. The club is in every sense a going concern, and its schedule of monthly exhibitions, lectures, etc., is a model publication. A reference and lending library is attached to the club, and there is also a benevolent fund for the assistance of distressed members. The club has four times competed for the Affiliated Societies' Cup, for fruit, at the Royal Horticultural Society's Fruit Show, and has won two first and two second prizes. Mr. Wallis is justly proud of the splendid work the club is doing, and, we may add, the club is very proud of its secretary.

Royal Horticultural Society's Fortnightly Meeting.—The next meeting and exhibition of the Royal Horticultural Society will be held on Wednesday, the 14th inst. The change that has been made in the day of meeting is due to the desire of the Council to avoid the inconvenience caused to exhibitors when the exhibition is held on the day following a Bank holiday.

Additions to the Kew Library.—In the form of an appendix to the Kew Bulletin a list of the books added to the Kew Library during 1912 has been published. It is so arranged that it can be cut up and added to the original catalogue. Forty-eight octavo pages contain the titles, authors, date, etc., of the books purchased or presented, and there are probably close upon a thousand such additions.

American Gooseberry Mildew.—According to the official report that has recently come to hand, the Board of Agriculture have received information that the summer stage of American gooseberry mildew (Sphaerotheca Mors uvae) has been discovered in a Kent garden, and also in a Cambridgeshire garden. All gooseberry growers are advised to examine their bushes carefully, and should any sign of disease be found to spray their bushes with a solution of liver of sulphur (1lb. to 32 gallons of water). Growers of gooseberries are reminded that by Article 3 of the American Gooseberry Mildew Order of 1911 they are required to report the presence of this disease on their premises to the Board or the clerk of the local authority for the district either directly or through an inspector, and that the failure to report is punishable by a fine.

Insect Pests and Spraying Apparatus.—In view of the activity at the present season of the numerous enemies of plant life that are more or less destructive to useful garden crops and ornamental plants, we shall, in our next issue (May 17) devote special attention to the insect pests that commit their ravages during the spring and summer months, and the best means of combating them. The articles relating to this important aspect of garden practice will be comprehensive in scope, and the information they will contain will be especially adapted to the work that has to be commenced at once, and persevered with during the summer months. In addition to the articles dealing with the enemies of fruit trees and vegetable crops, and the pests of ornamental plants grown under glass, the issue will contain a full report, with illustrations, of the comprehensive trials of spraying machines and syringes recently carried out by the Royal Horticultural Society at Wisley.

Another Great Show at Ghent.—Not satisfied with the grand exhibition so fully reported and illustrated in our issue of May 3, the Ghent Horticulturists have already made preliminary arrangements for a grand display from August 9 to August 18 in the same splendid buildings. The Cercle Horticole Van Houtte is organising this exhibition, and, besides providing for ferns, palms, cycads, etc., the schedule will have classes for roses, begonias, gloxinias, pelargoniums, dahlias, liliums, and most kinds of seasonable hardy flowers and greenhouse plants. An international jury will be nominated shortly.

Messrs. William Bull and Sons are holding their annual special flower show at King's Road, Chelsea, this week, but, though the exhibition proper finishes Saturday, May 10, there will be plenty to see if visitors should attend during the holiday week. The large winter garden has been made very gay with orchids, rambling roses, liliums, and a splendid lot of fine amaryllis. Crowds of visitors have admired the rarity and beauty of the flowers, and the elegance and excellence of their arrangement with palms, tree ferns, and other suitable foliage plants. On Monday, May 5, the opening day, there was a record attendance. The great feature of the exhibition is a very handsome seedling odontoglossum bred from some of the finest blotched varieties. This is O. crispum Princess Mary; the plant carries two spikes, and one spike has ten shapely blooms finely blotched with rich red-brown on a blush-white ground. There is a little purple shading around some of the red blotches, and a handsome golden crest adds to the general beauty of the flower. An illustration of a single flower is given on page 345. Needless to say, this odontoglossum raised by the Messrs. Bull has been greatly admired.

The Crystal Palace.—At a meeting of the London County Council held on Tuesday last, the following recommendation of the General Purposes Committee was agreed to: "Without expressing any opinion at this moment as to the commercial value of the Crystal Palace and grounds, the Council do seek from Parliament authority to subscribe £30,000 towards the acquisition of the land as an open space, subject to being satisfied as to the arrangements for its maintenance and control." Lord Plymouth, who purchased the Crystal Palace and grounds, is willing to convey them to trustees, national or municipal, for the price at which he bought them. The Lord Mayor of London is making an effort to secure the sum needed to make the purchase, and this grant from the London County Council will have a distinctly good influence in the right direction. The L.C.C. estimates for the year for the business conducted under the Parks and Open Spaces Committee were £162,140.

The Kew Guild Dinner.—This interesting and pleasant function will be held on Wednesday, the 21st inst., the second day of the Royal Horticultural Society's Chelsea exhibition, at the Holborn Restaurant, at 7.30 p.m. The dinner will be preceded by the annual general meeting, which will commence at 6.45 p.m. Mr. William Goldring will preside at the annual dinner, which will be held in the Caledonian Room. Many old Kewites now home from abroad will be present, and a good gathering is anticipated. Members wishing to attend should communicate with the secretary of the Guild, Mr. H. Cowley, South Side, Kew Green.

Oxford Botanic Gardens.—The annual report for 1912 on these gardens has been issued, and the curators state that the total receipts for the year (including the sum of £70 paid by the Sherardian Professor of Botany out of fees received by him from students) have been £790, to which is added 6s. 3d. balance brought forward from the previous year, making a total of £790 6s. 3d. The expenditure amounted to £792 19s. 8½d., thus leaving a debit balance of £2 13s. 5½d. on the account. The expenditure in 1910 was £788 7s. 9½d., and in 1911 £797 17s. 8d. The expenditure on repairs has again been heavy, amounting to £176 10s. 3d., as compared with £158 5s. 11d. in 1911. This increase of expenditure, which accounts for the debit balance on the account, is solely due to necessary repairs which had to be undertaken at a moment's notice to one of the large boilers.

Destruction of Wild Plants.—In the course of his presidential address at the annual meeting of the Newbury Field Club, the Hon. A. E. Gathorne-Hardy referred to the destruction of many wild plants, owing to the rapacity and greed of some persons and the ignorance of others. He was glad to say that some change was coming over the English people, who now appeared to derive more pleasure from watching birds and wild animals than from destroying them. He trusted that at no distant date they would experience more enjoyment from watching the development of native plants than from rooting them up.

The Late Mr. Edward Webb's Estate.—The late Mr. Edward Webb, who was the senior partner of the firm of Messrs. E. Webb and Sons, the well-known seedsmen of Wordsley, Stourbridge, left estate of the value of £947,633.

School Gardening in Leicestershire.—In the course of an address recently given before the Leicestershire Chamber of Agriculture, Mr. W. A. Brockington stated that the teaching of gardening should not be to show boys how to grow a few vegetables, but to lay the foundation of a scientific habit of mind, and to teach something of the principles that underlie all cultivation of the soil. Between 1902 and 1908 the number of school gardens in England increased from 349 to 1,505, and the number of scholars under instruction from 5,501 to 24,316. In Leicestershire they had established school gardens wherever the schoolmaster was willing and able to undertake the work, and the managers of the school were acquiescent. In 1903 there were two school

gardens in the county; last year there were 52, with 652 pupils; and the number was increasing, and would further increase if the movement were not retarded in many places by local prejudice. The time would come when a thorough training in practical arts would form part of the education of all rural teachers, and meanwhile there was ground for satisfaction in the amount of teaching ability already placed at the disposal of rural elementary schools. In Leicestershire gardening was invariably taught by the regular school staff.

Pruning Town Trees.—Referring to the pruning of trees in towns which was mentioned in the "Note of the Week" which appeared in our issue of April 26, Mr. Basil Holmes, secretary of the Metropolitan Public Gardens' Association, writes: "The association has found that when pruning is necessary it is quite possible, in any but narrow thoroughfares, to do the needful, even in the case of plane trees, without reducing them to the condition of clothes props, and entirely destroying their natural beauty. Straight, clean stems are requisite up to a height sufficient to clear all traffic, and a system of internal thinning-out is adopted, so that ample light and air pass through the trees. Also, where such trees are too closely planted, the alternate ones should be entirely removed instead of mutilating the whole row."

Lady Downe's Seedling Grape.—It is a point of some importance, and certainly not without interest, that those who have to obtain their supplies of grapes through the several trade channels, and appreciate the high quality of Lady Downe's Seedling, have to be largely dependent on the grape growers at the Cape for fruit of this excellent grape. This fine late grape was raised in the gardens of Beningborough Hall, York, about 1835, and was distributed some eight years later. It was slow in making its way into general cultivation, and at no time has it attained to a high degree of popularity in this country, notwithstanding the fact that there are no special difficulties connected with its cultivation, and that the fruit is richly flavoured. While this excellent grape has failed to obtain a position proportionate to its merits in British gardens, it has become highly popular with growers at the Cape, and large quantities are now being sent to the British markets, where the fruit meets with a ready sale, owing to its good appearance and rich flavour.

ROSE MDME. EDOUARD HERIOT.

Flowers orange-vermilion when opening, deep pink shaded with orange when fully expanded. A Pernetiana rose, raised by M. J. Pernet-Ducher. Gold Medal, N.R.S., May 1. Messrs. G. Beckwith and Son, Ware Road Nurseries, Hoddesdon.

ASPARAGUS:

ITS LITERARY AND CULINARY ASSOCIATIONS.

This well-known and delicious vegetable has been called the chameleon of the kitchen, and the season of 1912 was exceptionally good; it was cheap and abundant, and of excellent flavour, provided you were able to secure a good type.

There are many varieties of this succulent and favourite vegetable, both English and foreign. France grows it in large quantities, not only for its own, but for the English market; but, nice as the French may be, I think all will allow that the English "grass" carries the palm for its delicious flavour. Holland, says the grand old horticulturist Loudon (of whom we shall speak later on in this paper) claimed that asparagus was brought to the greatest perfection in our own country, unless Holland perhaps; but we, I think, have succeeded in surpassing that country in these later years, and Loudon adds that without exception England could claim that the asparagus beds in his day at Deptford and Mortlake were the largest in the world. John Evelyn, the diarist tells us that Battersea was a noted place for asparagus growing, and in the beginning of the last century it was cultivated largely in the Chelsea fields for the Covent Garden Market.

Evelyn's Eulogy.—John Evelyn, just mentioned, says, in his "Acetaria": "Next to flesh nothing is so nourishing as asparagus." This is as may be, and modern physicians might not, perhaps, endorse his verdict. Nevertheless, it is vastly appetising, and can be served in so many forms that it is a veritable chameleon of the kitchen. It is supposed, in old Herbals and such-like books, to soothe and still the action of the heart, in the same manner as foxgloves, and also to possess lithic and other medicinal properties.

Although there are many methods of cooking asparagus, the old-fashioned, and simplest, always remains the best, i.e., immerse the bundle in salted water, standing it upright, so that about a couple of inches are above the water. The last five minutes of boiling or steaming the bundle should be laid down in the water, and the asparagus will be evenly cooked. Serve with melted or oiled butter, and hard-boiled, new-laid eggs divided into pieces and placed around the dish are a pretty and useful adjunct, and makes a very nice entrée. There is a decided difference of opinion as to whether asparagus should be eaten hot or cold, but experts are inclined to agree that it is the one thing in the regions of gastronomy which should be lukewarm, neither hot nor cold. Such a state of things seems to bring out the flavour best. It is debatable, but certainly worth trying.

Asparagus makes a delicious salad eaten cold with olive oil and vinegar. The cerebrated French author, Fontenelle, who was a nephew of Corneille, and lived to the age of one hundred (1657-1757), was particularly fond of asparagus served with oil, but he was intimately acquainted with an Abbé who preferred to eat his asparagus with butter. One day the Abbé dropped in unexpectedly to dine, and Fontenelle, who had ordered his favourite dish, with great forethought directed that half should be dressed with oil, and the rest with butter. Suddenly the Abbé, a man of plethoric habit, fell down in a fit, and died within five minutes. Fontenelle, without a moment's delay, called to the cook, "Dress them all with oil, all with oil, as I told you at first."

"The Grass Club" is a curious old-fashioned London dining club, that meets only once a year, its only object being the cult of asparagus, and its members are almost entirely prosperous middle-aged City men, who, for once in a way, abjure kickshaws and stick to plain English food. The dinner is annually the same. First, real turtle soup, thick and clear, after which mutton cutlets, and in front of every member is placed a dish of ten pounds of asparagus. Ten pounds of asparagus means about five hundred stalks, and the whole idea of the feast is that, at any rate, once a year no man present shall be able to say that he cannot get enough asparagus. He is not, of course, bound to eat it all, but it is amusing how much is consumed before the company breaks up. A greedy custom, maybe, but with something quaint and attractive about it nevertheless.

Charles Lamb was of opinion that asparagus "inspired gentle thoughts." Charles Dickens refers to it in "Dombey and Son" when describing Dr. Blimber's educational establishment at Brighton: "It was a great hothouse, in which there was a forcing apparatus incessantly at work. All the boys blew before their time. Mental green peas were produced at Christmas, and intellectual asparagus all the year round."

The anecdotal end of the asparagus is as substantial as the actual. Dean Swift and George Faulkener, the Dublin Alderman and bookseller, who printed and published for Swift, were dining at the Deanery. Asparagus was served, and the guest asked for a second helping. Swift pointed to his plate, and said, "Sir, first finish what is before you!" "What, sir," answered Faulkener, "eat my stalks?" "Ay, sir," replied the Dean in his most imperious manner, "eat your stalks, or you will have no more. King William the Third always ate his stalks." When relating this story Faulkener was often asked, "Did you really eat your stalks?" And he always replied, "Yes, certainly; and if you had been dining with Dean Swift, you would have eaten your stalks too."

It is quite a poetic idea that the asparagus is really a lily, or, rather, of the lily family, and it is written: "When we hear that it is ranked with the asphodelos, we are ready to believe that the fields of asphodel in which the blessed roam in Elysium must be beds of asparagus." It is pleasant to think that this Elysian lily, though it does not look in the least like a lily when it comes to table, is a real old English delicacy. One of its old countryside names is paddock cheese. Kindred plants are Solomon's seal and butcher's broom. But these are merely the bye-ways of botany.

A dictionary of 1791 says, "Sparrow grass is now so general that 'asparagus' has an air of stiffness and pedantry." Samuel Pepys used "sparrow-grass" and also "sparagus." A grave Latin author refers to the cookery of lobster with asparagus, a course which has been adopted by modern chefs, and in Juvenal's Eleventh Satire he promises his friend Perseus a plate of mountain asparagus which had been gathered by his farmer's wife. Throughout classical gastronomic literature there are innumerable references to the virtues and excellences of asparagus, and its alkaloid asparagin, so that one may gratefully welcome its vernal appearance with every mark of gentle appreciation.

And now I should like to give you a charade which an uncle of mine quoted when I was a child. It might have been his own. It runs thus:

> "My first's a little thing that hops;
> My second yields us good hay crops;
> My whole we eat with mutton chops."

The answer is obvious after the dictionary of 1791.

H. C. Philbrick.

(To be continued.)

JANKÆA HELDREICHI.

It is probably fortunate that the wonderfully beautiful Jankæa Heldreichi is so scarce and expensive that it is beyond the means of the average lover of alpine flowers. I may be met with the argument that it would be more widely grown were it cheaper to begin with, but I would meet this with the counter-argument that if it were cheaper there would be far more who would be doomed to lament their temerity in purchasing it with weeping and wailing and gnashing of teeth. The truth is that the Jankæa cannot endure our climate in any but a few favoured spots on the rock-work, and that it is not suited for the many who cannot always give it what it wants.

Have we not seen many plants, carefully purchased, planted according to the most approved teaching, and tended with watchful care, succumb despite of all the coaxing and attention that could be given to them? How few could be seen, a year or two after, happily established far from their Balkan home in this land of ours! These could be counted on the fingers of one hand, and it would be wrong to endeavour to persuade the reader to indulge in a plant of Jankæa Heldreichi. Not that it cannot be cultivated, for, so far as that goes, the lovely Eritirichium nanum is a still more difficult plant, but there are few—few indeed—who can succeed permanently with this silvery-foliaged, lovely pale violet flower.

One calls it silvery-leaved, and this is because the foliage is covered with a white, almost felt-like, down which gives it that appearance. This is the cause of its dislike to our climate. That protection against the dry cold of winter in a dry climate is its weakness in ours. Wet above means death to the Jankæa, yet it must not be dry at the roots. Its ideal home is a little, very tiny, cavern in the rock-work, where not a drop of rain can reach its leaves, and where it is shielded from the sun, yet where its roots can be kept constantly moist. It is a treat to see it in such a place, thriving and increasing from year to year, and giving its little flowers on the silvery, downy leaves. Ah! how sad it is to fail with such a charming plant, and how glowing the delight one experiences when one sees it doing well!

Such a plant is worth trying, even at the cost of a pound or two, to the enthusiast with means, who is not content with being defeated, but who is resolved to succeed. To the man who wishes to soar to the highest summits of alpine culture, the conquering of the Jankæa is put forward as an achievement worth making a bold bid for.

S. Arnott.

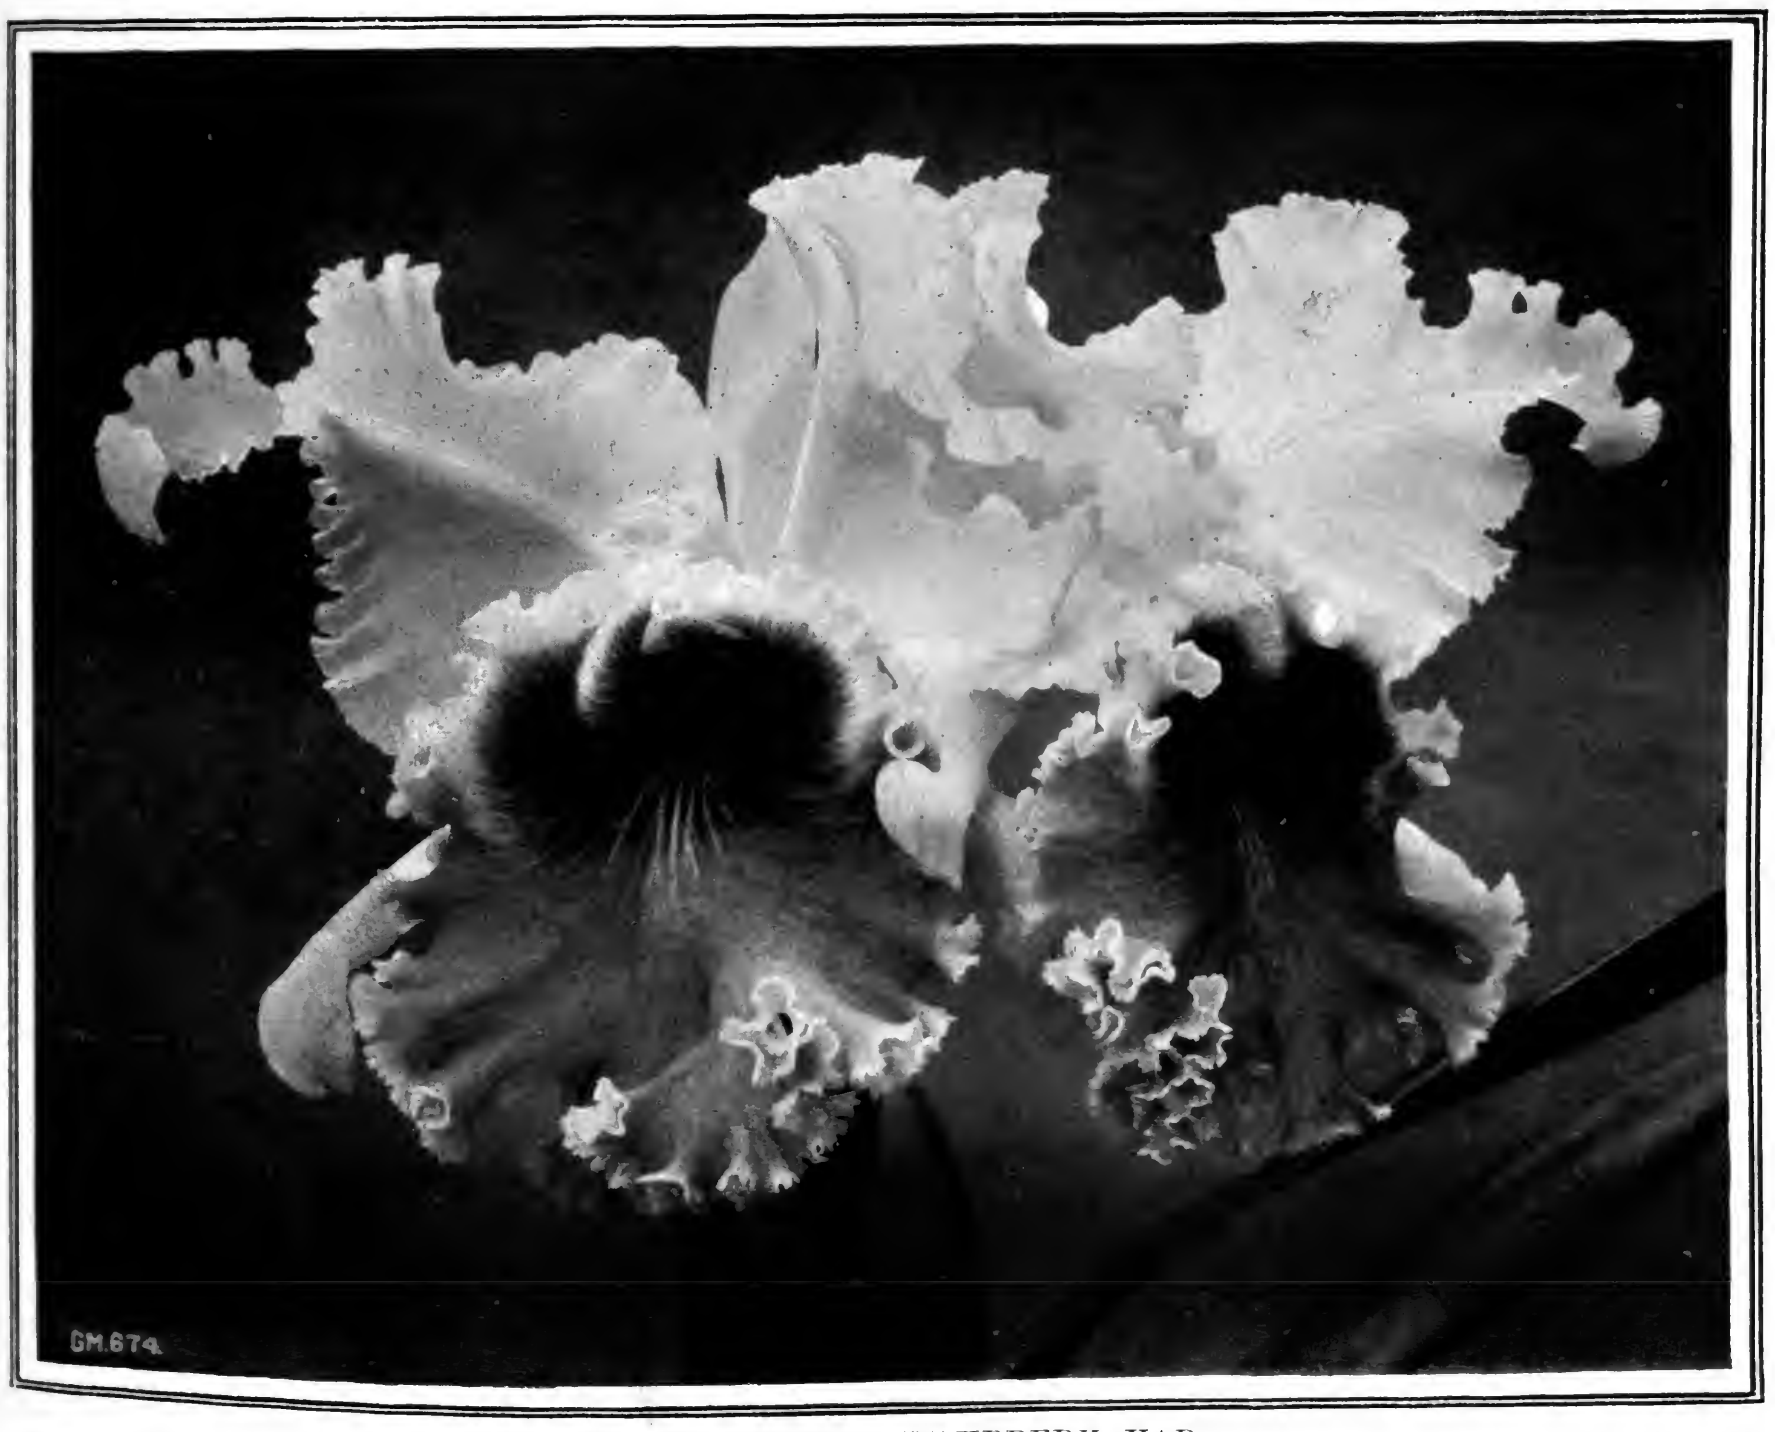
Haywards Heath.

HISTORY OF ORCHID CULTURE IN GREAT BRITAIN.

Fashion, which from time well-nigh immemorial has exercised a powerful influence upon the garden, as on other matters that enter into the affairs of everyday life, has been far more kindly disposed to orchids than to any other of the more important classes of ornamental plants to which British cultivators give so freely of their loving care and skill. The "fickle jade" would indeed appear to have been so fascinated by the wondrous form and exquisite colouring of their flowers as to have strenuously opposed the endeavours of other members of the vegetable kingdom to usurp their place in her affections. She has on more than one occasion in the history of gardening in the British Isles become tired of hardy plants, notwithstanding their manifold charms and the intense interest associated with them. In like manner she has shown us that she no longer delights in the great colour schemes that for a considerable period formed a predominant feature of the attractions of the flower gardens of this country. In remarkable contrast to the influence of Fashion on other occupants of the garden there has been evinced a constancy to these delightful denizens of the forest and mountain side of tropical and semi-tropical countries that is hardly short of the marvellous. Hence it is that as we call to mind some of the more interesting facts relating to the history of orchids under cultivation, or engage in research for the purpose of refreshing the mind on points that are not quite clear, there is no danger of being confronted by reminders of the days when these plants were ousted from their high position in the estimation of the flower-loving community to make way for some other class that had caught the public fancy.



CATTLEYA TITYUS SHRUBBERY VAR.

A beautiful variety, obtained from a cross between C. Enid and C. Octave Doin; the flowers large, the sepals and petals blush-white, and the lip crimson-purple with golden blotches. A.M., R.H.S., March 22, 1913.

From the earliest period of the history of the cult of the orchid in this country until the present time there has been continuous progress, both in the culture of the plants, and in the development of the taste for their flowers. There may have been, as, indeed, was the case, some variation in the rate of progress, owing to difficulties that had from time to time to be surmounted. At one period it may have been the difficulty experienced in maintaining the plants in health, more especially in the early days when the conditions essential to successful culture were but imperfectly understood. At another, progress would be comparatively slow in consequence of the importations of plants not being sufficient to balance the losses that were unquestionably heavy in the case of some of the kinds, more especially those which have their home in cool regions, and consequently languish when subjected to a temperature largely in excess of their requirements. There has been no great set-back due to a change in the public taste.

Some of the many kinds that have their home in the lowlands of the tropics, and require a high temperature and a humid atmosphere, have lost the high degree of popularity they once enjoyed, but this has been chiefly due to the heat that has to be endured in the enjoyment of the beauty of the flowers. If a proof is required of the continuance of a deep interest in orchids, it may be readily found. Probably that to be found in the records of the exhibitions which have been held within the Metropolis will be as conclusive as any. Turning to these it is seen that orchids formed an important feature of the great summer shows held by the Royal Horticultural Society at Chiswick during the first half of the last century. It is seen also that they were so

attractive to the visitors as to render it difficult to fully enjoy the charms of the finely-developed specimens. Some readers may remember the collections of orchids that were contributed to the summer shows held at South Kensington, Regent's Park, and the Crystal Palace during a part of the second half of the last century, and the crowded state of these parts of the exhibitions in which they were arranged. Coming to more recent periods, many thousands of readers will have a lively recollection of the glorious displays of orchids at the Temple shows during the past quarter of a century, and the interest evinced in them by the visitors that crowded the tents in which they were arranged.

CYMBIDIUM SCHLEGELI.

A fine hybrid between C. insigne and C. Wiganiana; flowers cream colour with purplish markings on petals and sepals, and red spots on lip. A.M., R.H.S., January 23, 1912.

Early History.

To find unquestionable evidence of the period at which orchids were first cultivated in Great Britain, we have to extend our researches further back into the distant past than is commonly supposed to be necessary. While orchids were not grown to any considerable extent until the dawn of the last century, a beginning had been made long anterior thereto. The fact has been placed on record by Dr. W. B. Hemsley that in 1731 Peter Collinson received from a correspondent in the Bahamas a dried specimen of Bletia verecunda, as a contribution to his herbarium. Collinson, recognising some degree of vitality in the bulb, sent it to one of his friends—a Mr. Wager—who, having put it in a pot, placed it on a hot-bed, where it soon started into growth, and in due course produced flowers. This, so far as is known, is the first orchid from tropical regions that was cultivated in British gardens; but this does not appear to have been a great triumph of the cultural art, for nothing is known of the plant subsequent to flower development. Reference was made by Miller in the second edition of his "Dictionary of Gardening," published in 1768, to several species of Epidendrum, but with these he failed, as he states that "The plants cannot by any art yet known be cultivated."

Ten years after the publication of Miller's "Dictionary," Dr. J. Fothergill brought from China Phaius grandifolius and Cymbidium ensifolium. There is no record of the flowering of the cymbidium, but the phaius produced its bold spikes of purplish flowers within a comparatively short period of its introduction in the gardens of Mrs. Hird, at Appleby Bridge, Yorkshire. Epidendrum cochleatum is recorded as having flowered for the first time in England in 1787, the specimen being in the plant stove in the Royal Botanic Gardens, Kew, where E. fragrans bloomed in the following year. By the year 1794 fifteen species had found a home at Kew, and at the end of the eighteenth century, the Kew collection contained twenty-five species. The most noteworthy of the kinds that were received at Kew between the introduction of the two epidendrums and the close of the century were Epidendrum ciliare, Lycaste Barringtoniæ, and Oncidium altissimum, and of the trio the first-named is still in cultivation.

Introduction of Species.

Until about one hundred years ago, when the influence of the Royal Horticultural Society, which had obtained its charter in 1809, was being felt, orchids were looked upon in the light of curiosities, rather than as plants worthy of being cultivated for the adornment of the plant house. This is not altogether surprising, considering how large was the proportion of kinds that were "more curious than beautiful," and that they were assumed to be parasitic in their manner of growth, and were so described in the periodic literature of the time.

In the second decade of the last century views began to change with regard to orchids, for by that time some species possessing a greater degree of beauty than the earliest kinds were introduced, and recognised by owners of gardens in which provision had been made for the growth of tropical plants as worthy of cultivation for the beauty of their flowers. A brisk demand arose for the finer kinds, and in 1812 Messrs. Loddiges and Sons commenced their cultivation for sale in their nurseries at Hackney, which soon became famous as the headquarters of the commercial side of the orchid cult, and this fame extended over forty years, in fact until the establishment was broken up in 1852. During the forty years this firm introduced a considerable number of species, and became the leading authorities on all that related to orchids and their cultivation, and did much to stimulate an interest in them and to extend their culture.

With the stimulus that a well-organised trade establishment, such as that of the Messrs. Loddiges, would be able to give the introduction of new species increased with considerable rapidity. Britishers who occupied official positions in tropical and sub-tropical regions, and were interested in plants, gave attention to the collection of orchids, as far as their opportunities would permit, and were successful in the introduction of many species of merit. As evidence of this, it may be mentioned that within a short time of the Messrs. Loddiges commencing the culture of orchids, Dr. Roxburgh introduced from India the first aërides, dendrobium, and vanda that reached this country. As the cultivation of orchids extended collectors were despatched to countries in which they form part of the native flora, and between 1830 and 1850 many new species were introduced, and large numbers of plants of known kinds collected.

Chief among the collectors of this period were Lobb, who discovered many of the finest aërides, saccolabiums, and vandas; Griffith, who introduced numerous cymbidiums and dendrobiums; Gibson, who added several species of dendrobiums to those already known; and Barker, Hartweg, and Skinner, who, in their expeditions to Guatemala, Mexico, and the flanks of the Andes, enriched collections with many cattleyas, lælias, and odontoglossums of great beauty.

The species that were introduced by the earlier collectors included Cattleya labiata, 1818, which, for a time, was lost to cultivation; C. Mossiæ, 1836; C. Skinneri,

536, Cypripedium barbatum, 1838; C. nodatum, C. insigne, 1819; Dendrobium chrysotoxum, 1845; D. Dalhousianum, 1837; D. Devonianum, 1837; D. densiflorum, 1829; D. Farmeri, 1847; and D. nobile, 1836; Odontoglossum crispum, 1844; O. grande, 1849; O. Rossi, 1839; Zygopetalum crinitum, 1829; and Z. Mackayi, 1825.

Since the middle of the last century large numbers of species have been introduced, and the best known of the collectors are W. Boxall, who introduced many cypripediums and dendrobiums; C. Curtis, who was successful in the discovery of angræcums and cypripediums; Carder, whose greatest successes were with masdevallias and odontoglossums; and Micholitz, who included some fine dendrobiums among his introductions. The new species that have been introduced during this period would make a somewhat formidable list, and, for the present purpose, it will suffice to mention a few that are of special purpose in their respective genera, namely, Cattleya Mendeli, 1884; C. Forbesi, 1823; C. Trianæ, 1860; Cypripedium Dayanum, 1860; C. Spicerianum, 1879; C. Lawrenceanum, 1878; C. Chamberlainianum, 1891; C. Charlesworthi, C. Rothschildianum, 1888; Cochlioda Noetzliana, 1891, which has been used so largely and successfully in the production of brilliantly-coloured bigenic and other hybrids; Dendrobium Phalænopsis, 1880; D. Wardianum, 1863; Lælia elegans, 1845; and L. purpurata, 1852.

Early Cultivation.

Not until the first half of the last century was well advanced did the general body of cultivators achieve success with any considerable number of species that the activities of the collectors and the enterprise of the nurserymen had placed at their disposal. In those days physical geography was practically absent from educational schemes, and, as the cultivators had no means of obtaining exact information on the conditions that obtain in the various districts in which the orchids then abounded, it is not surprising they should have attempted to grow the whole of the kinds under the same conditions, and thousands of plants should, as a consequence, have been annually lost.

Even the Loddiges, who, in the course of their business, were in constant communication with correspondents in the orchid-inhabited countries, and with collectors, made the mistake of attempting to grow all the orchids under the same conditions, and these best suited to the requirements of the kinds that have their haunts in an Indian jungle, or in the forests of the lowlands of the equatorial regions of South America. Their orchid house was heated by brick flues, and the temperature maintained at as high a level as this system would permit, and in the centre was a tan bed, which was kept moist by frequent waterings for the purpose of maintaining a high degree of humidity in the atmosphere. No air was admitted from without, and, as will be readily imagined, those kinds which came from considerable altitudes, such as the cattleyas, lælias, and odontoglossums, quickly succumbed to the high temperature and stifling atmosphere to which they were subjected. The house provided by Messrs. Loddiges for their orchids was accepted by the general body of cultivators as the model for such structures, with, as already intimated, disastrous results. In the early part of the past century it was regarded as a remarkable achievement to successfully grow an aërides, and, as Mr. Fairbairn, who was then gardener to Prince Leopold, at Claremont, succeeded in growing and flowering Aërides odoratum, the feat attracted much attention among orchidists. Turning to the "Transactions" of the Royal Horticultural Society, Vol. VII., p. 499, for particulars of his method of procedure, it is found that he put the plant, when first received, into a basket of wood with old tan and moss, and hung it up in the pine house, where it was exposed to the summer sun, and to the fireheat in winter. A tub of water was placed near it, and in this the basket was plunged six or seven times a day, or as often as he passed near it. Mr. Fairbairn was, it may be mentioned, the first to flower the richly-coloured Renanthera coccinea.

LÆLIO-CATTLEYA NELLA.

A handsome hybrid; flowers deep rose-purple with old gold markings in the throat. F.C.C., R.H.S., December 19, 1911.

An attempt was made at Kew about the year 1824 to improve the cultivation of orchids. A bed was formed in the propagating house with fibrous soil and portions of branches of trees, to which plants were attached. These grew more freely for a short period than under the conditions which previously obtained, but they ultimately succumbed to the heat and moisture, and the only effect of the change was to prolong their life for a short time. Some years later Mr. Lockhart, who was then curator of the Trinidad Botanic Garden, sent to Kew plants of Oncidium Papilio, Stanhopea insignis, and several

other kinds, which were growing on cut branches of trees, and with them instructions for their cultivation. These latter were acted upon, the results were satisfactory, and, in course of time, assisted in bringing about an improvement in cultural methods.

Orchids at Chiswick.

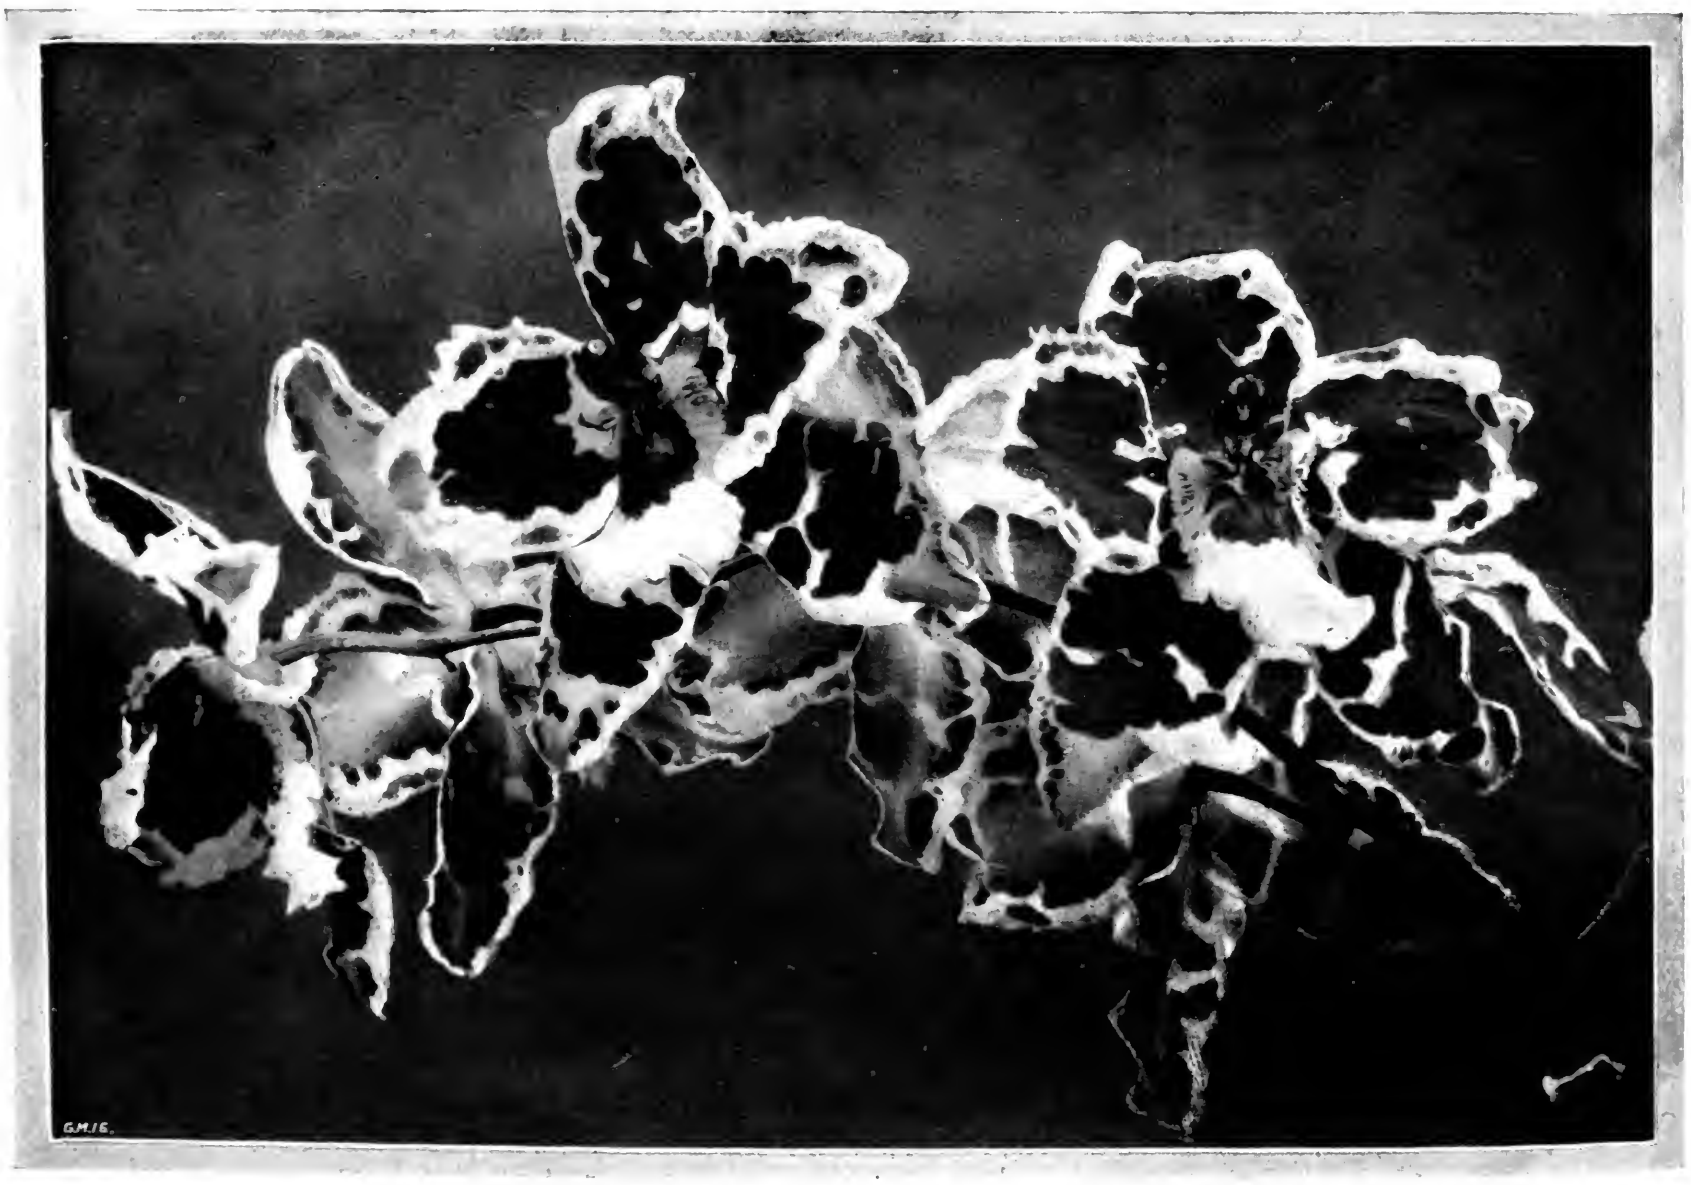
An endeavour was made in the Royal Horticultural Society's gardens at Chiswick to discover the cause of the failure to grow these plants successfully, but, unfortunately, it did not succeed. A plant stove was wholly devoted to orchids, and Mr. (later Dr.) Lindley, who was about this time appointed assistant secretary, had the supervision of the structure. "All the earliest experiments were," we are told, "unsuccessful, the plants were lost as quickly as they were received, and, when a single specimen was preserved out of an entire collection, some success was thought to have been achieved." The failure induced Lindley to institute inquiries regarding the conditions that obtain in the countries in which orchids are found growing naturally. His investigations were, unfortunately, also unsuccessful, owing to his having taken too narrow a view of the subject, or to those to whom he applied for information having given him particulars relating to areas in which the conditions were very similar. In the paper read at a meeting of the Royal Horticultural Society he stated that the collectors which the society had sent to Brazil had informed him that orchids "exclusively occupy damp woods and rich valleys among vegetation of a most luxuriant description, by which they are embowered." By Dr. Wallich, who had introduced several of the most beautiful of the Indian dendrobiums, he was told that, "In Nepal the thicker the forest, the more shady the trees, the richer and blacker the soil, the more profuse the orchids."

No account was taken of the conditions that obtain in the regions in which the cattleyas, lælias, odontoglossums, masdevallias, and other of the intermediate and cool orchids flourish. With such data Lindley formed a code of culture in which a high temperature and excessive humidity were recommended as essential to success, and this was acted upon by growers for a long series of years. Gibson, Gardner, Lobb, Motley, and Skinner, all of whom had much experience in collecting at the higher altitudes, did their best to warn cultivators against the practice of attempting to grow orchids from temperate regions under conditions similar to those which obtain in the lowlands at the Equator. The importance of these warnings was not readily appreciated, and for a considerable period England was, in the words of the late Sir Joseph Hooker, "the grave of tropical orchids."

Change in Early Cultural Methods.

A change in cultural methods was eventually brought about, not as the result of the protest of the collectors, but by the intelligent work of some practical gardeners who had collections of orchids under their charge. One of the first of these to demonstrate the importance of a moderate temperature and fresh air was Joseph Cooper, gardener at Wentworth, Rotherham, the residence of Earl Fitzwilliam, where, in 1835, the collection of orchids was extensive, and in splendid condition. Not far distant were the Chatsworth gardens, in which Joseph Paxton, who was then in charge, had formed a collection containing upwards of three hundred species, these including the finest that had been introduced. Paxton, like his neighbour Cooper, adopted a rational course of procedure, and succeeded in growing even the most difficult kinds to a high state of development. Chatsworth was then, as now, visited by all the leading cultivators in the country, and the robust health of the plants so impressed them that, in course of time, the example that had been set by Paxton was generally followed. Donald Beaton, who was, perhaps, best known for his work when gardener at Shrubland Park, was well versed in orchid culture, and with the aid of a ready pen did good service in bringing about the much-needed reform in cultural methods.

Towards the end of the first half of the last century collections were becoming numerous, some of the most important being those of Mrs. Lawrence, at Ealing Park; Mr. J. J. Blandy; Mr. R. S. Holford, at Westonbirt; Mr. Sigismund Rücker, at West Hill, Wandsworth; Mr. J. H. Schröder, at Stamford Green; Mr. R. Hanbury, at Poles, Ware; and of the Duke of Devonshire, at Chatsworth. From these collections, with the exception, perhaps, of that at Chatsworth, remarkably fine specimens were contributed to the Royal Horticultural Society's exhibitions at Chiswick, the kinds that properly belong to the East India house being represented by splendidly-developed specimens.



ODONTOGLOSSUM THAIS.

A distinct and beautiful hybrid; flowers blush, blotched with rose-purple. F.C.C., R.H.S., November 21, 1911.

Modern Cultivation.

By the end of the first decade of the second half of the past century an immense improvement had been made in methods of culture, and it was generally acknowledged that the various kinds should be classified according to their cultural requirements, and be grown in separate houses, where they could be placed under the conditions most favourable to their full development. One important change was the erection of houses much lighter in construction than

had previously been considered desirable; and the reduction in the woodwork, and the increase in the glass area enabled the plants to enjoy the light so essential to healthy growth. The houses were also provided with the means of ample ventilation, and the best of these were fitted with ventilators that opened direct on to the hot-water pipes for the purpose of warming the air, as it made its way into the house. By this time the value of fibrous peat of high quality and good sphagnum moss for the epiphytal kinds was well known, and the knowledge acted upon. The practice of the most successful growers did not differ greatly from that which now obtains at the present time, except that the using up of the finest peat for orchids has rendered the use of osmunda and polypodium fibre necessary. The employment of broken leaves in the preparation of orchid composts is a quite recent innovation, but the fallacy with regard to the use of manurial matter in the cultivation of orchids has long been with us, and will probably endure to the end.

Cultivators at the present day have, in the all-important work of combating insect pests, an immense advantage, as compared with past generations of orchid growers. Little was known of the value of quarantine in bygone days, and plants were introduced to collections without regard to their being infested or not, and again and again were orchids subjected to insect attacks that might easily have been avoided. To rid the plants of insects to which they had become a prey was no light matter, for sponging is very tedious, and fumigating with the materials that were then available far from effective. Now, with the aid that vapourising with nicotine compounds is so well able to render, the keeping of insect pests in subjection is not attended with any special difficulty.

From the middle of the last century orchid culture extended with considerable rapidity, and, in a comparatively short time, the collections became fairly numerous. Especially noteworthy among the earliest of these were Mr. C. B. Warner's, Mr. C. Webb's, and the Rev. W. Ellis's, at Hoddesdon, which, for a time, was a great centre of orchid culture. Not less important were the collections of Mr. William Marshall, V.M.H., at Enfield; Mr. J. Day, at Tottenham; Mr. Sam Mendel, at Manchester; and Mr. W. Lee, at Leatherhead.

Collections belonging to a still later period are very numerous, and conspicuous among them are: the collection of Lieut.-Colonel Sir George Holford, at Westonbirt (grower, Mr. H. G. Alexander), where the achievements in orchid growing and raising are a constant source of surprise; of Baron Bruno Schröder (gardener, Mr. E. Shill), at Egham, remarkable for its fine hybrids and varieties; of Sir Trevor Lawrence, V.M.H. (grower, Mr. H. White), at Burford Lodge, remarkable for the large number of botanical species it contains, as well as for the fine forms of other kinds; of the Duke of Marlborough, at Blenheim, in which Vanda cærulea is especially well grown; of Mrs. Cookson (gardener, Mr. J. H. Chapman), which is especially remarkable for its choice cypripediums and odontoglossums; of Mr. F. W. Moore (gardener, Mr. W. H. Page), at Chardwar, in which cypripediums form a strong feature; of Mr. De Barri Crawshay (gardener, Mr. W. J. Stables), Sevenoaks, of special interest for its splendid odontoglossum hybrids; of Mr. F. M. Ogilvie (gardener, Mr. W. Balmforth), in which are many fine hybrids; of Lord Rothschild (gardener, Mr. Dye), Tring Park; of Sir J. Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, and Mr. H. T. Pitt, Stamford Hill; Mr. W. Birkenshaw (gardener, Mr. T. J. Barker), Hessle; Mr. C. J. Lucas (gardener, Mr. G. Duncan), Warnham Court; Mr. W. Thompson (gardener, Mr. Stevens), Stone Hall; and Mr. W. Lee, Plumpton Hall.

Hybridisation.

One of the most interesting of the several aspects of the orchid cult is the creation of new forms, whether by hybridisation or cross-fertilisation. It may, at first sight, appear rather tedious watching the growth of the seedlings from the time of making their appearance until they reach the flowering stage, especially when, as in the case of Lælia caloglossa, this extends over nineteen years. This long period was, however, quite exceptional even in the early days of raising seedling orchids, and the rate at which seedlings attain the strength essential to flower production has been considerably accelerated by modern methods of procedure. It is, however, the common experience of raisers that the slightest impatience soon disappears, and the growth of the plants is watched with both pleasure and interest. That this is the case is proved to demonstration by the large number of growers who have engaged in the pleasant, and, it may be hoped, profitable work of raising seedlings.

The first hybrid orchids raised in this country were the result of the intelligence and manipulative skill of John Dominy, who long occupied an important position in the nurseries of Messrs. J. Veitch and Sons, and according to the available records, commenced his work of hybridisation exactly sixty years ago. He began by hybridising Cattleya guttata and C. Loddigesi, and obtained C. hybrida, of which five plants were shown at a meeting of the Royal Horticultural Society held in August, 1859. C. Dominiana, also from the same raiser, was shown at a meeting three months later. Still more noteworthy, from the decorative point of view, was Calanthe Veitchi, a hybrid between C. rosea and C. vestita, which flowered in 1859, and was exhibited at the meeting of the Royal Horticultural Society in December of that year, and received a First Class Certificate. In 1867 Phaius irroratus, a bigeneric hybrid, of which the parents were Calanthe vestita and Phaius grandifolius, and another of Dominy's successes, flowered. This was followed during the next few years by Cypripedium Harrisianum, C. vexillarium, and Lælio-cattleya Dominiana, a bigeneric hybrid between Cattleya Dowiana and Lælia purpurata, and of great beauty.

ODONTIODA BRADSHAWIÆ.

A finely-flowered example of the orange hybrid between Cochlioda Noetzliana and Odontoglossum crispum. This specimen was in a six-inch pot.

Before the last of the hybrids obtained from Dominy's earliest crosses had flowered new hybrids from other raisers bloomed, a point of interest as evidence that the work of raising seedling orchids was being taken up. There were, for instance, Cypripedium Ashburtoniæ and C. Crossianum, which were raised at Melchet Court, and had C. insigne as one of their parents; Chysis Sedeni and Zygopetalum Sedeni, raised by Mr. Seden in the Chelsea Nurseries; Dendrobium Ainsworthi, a hybrid between D. nobile and D. aureum, raised in Dr. Ainsworth's collection at Manchester; and Zygopetalum Clayi, a hybrid between Z. crinitum and Z. maxillare in Colonel Clay's collection at Birkenhead. In 1878 the first hybrid lycaste flowered in Mr. William Marshall's collection at

Enfield, and was subsequently named L. hybrida.

After this period hybrid orchids made their appearance in such large numbers that it is not possible to do more than refer briefly to a few of special interest. The first hybrid phalænopsis raised in this country was P. intermedia. The cross was made between P. Aphrodite and P. rosea to determine the origin of P. intermedia, and the results proved that the conjecture that it was a hybrid between these two species was correct.

The flowering of Brasso-cattleya Digbyano-Mossiæ, a hybrid between Brassia Digbyana and Cattleya Mossiæ, in 1889 was an event of considerable importance, and the lesson it afforded has been taken full advantage of, and we now have as the result a new race of orchids of wondrous beauty. In the next few years there appeared Cymbidium Veitchi, the first hybrid in the genus, Epiphronites Veitchi, a hybrid between Sophronites grandiflora and Epidendrum radicans, and the first of a new genus. Then followed Sophro-cattleyas, Epilælias, and Sophro-lælias, and a hybrid Phaius, Stanhopea, Sobralia, and Vanda, each of which is of interest, and possesses much beauty.

The year 1890 is of special interest in this connection, for therein flowered the first of the odontoglossums obtained by artificial hybridisation. This was raised at Armainvilliers, near Paris, from a cross between O. crispum and O. luteo-purpureum, and referred to as O. Wilckeanum, which, as had been assumed, is a natural hybrid between these two species. The first really distinct odontoglossum raised in this country was O. Cooksoni, a hybrid between O. Halli and O. crispum, which flowered in 1896. Two years later O. Loochristiense, O. spectabile, and O. Rolfæ made their appearance, but the first-named was found to be similar to O. Harvengtense, a natural hybrid. Subsequently many beautiful odontoglossums were introduced.

Of quite exceptional interest and beauty is Odontioda Vuylestekæ, a hybrid between Cochlioda Noetzliana and Odontoglossum Pescatorei, which was first exhibited at the Temple Show in 1904, and awarded a First Class Certificate and the Lindley Medal. Since, numerous additons have been made to this new genus, as the result of the activities of the hybridists. In 1911 Odonticidium Fowlerianum, a hybrid between Odontoglossum cirrhosum and Oncidium Forbesi, flowered and created much interest. Another bigeneric hybrid, in which an oncidium was one of the parents, bloomed in this year, namely Oncidioda Cybele, a hybrid between Cochlioda Noetzliana and Oncidium scarcodes. This also is of some importance as the first member of a new genus.

It would be pleasant, and of much interest to refer in some detail to the glorious Brasso-cattleyas and Lælio-cattleyas, the beautiful Cattleyas and Lælias, the handsome Cypripediums and Phaius, the brilliantly-coloured Odontiodas, and the exquisitely-coloured and elegant Odontoglossums that have been raised since the introduction of the earliest hybrids of which mention has been made. Their numbers are, however, so great as to render this impossible. It must, therefore, suffice to say that the work accomplished by the hybridists is such as to do honour to them, and to afford immense gratification to the great body of flower-lovers. The firms and private individuals who have specially distinguished themselves include Mr. H. G. Alexander, Messrs. Armstrong and Brown, Messrs. J. and A. McBean, Messrs. Bull and Sons, Messrs. Charlesworth and Co., Mr. J. H. Chapman, Sir J. Colman, Bart., Messrs. J. Cypher and Sons, Mr. De Barri Crawshay, the late Mr. D. O. Drewett, M. Firmin Lambeau, M. Linden, Messrs. S. Low and Co., Messrs. Mansell and Hatcher, M. Maron, Mr. W. H. Page, Messrs. Sander and Sons, Mr. W. Stevens, Messrs. J. Veitch and Sons, and Mr. C. Vuylsteke.

CYPRIPEDIUM ROUNDHEAD.

A handsome hybrid between C. nitens and C. Earl of Tankerville; the flowers large, the dorsal sepal white with greenish yellow base, and marked with purple spots, and the petals and lip greenish yellow shaded red-brown. F.C.C., R.H.S., April 1, 1913.

Extension of Orchid Culture.

During the past thirty or more years it has been highly pleasurable to watch the progress made by the many raisers of hybrid orchids and to have the opportunity of enjoying the charms of the new forms as they made their appearance in an endless procession. Not less has been the pleasure derived from the evidence obtainable on all sides of an extension of orchid culture throughout the kingdom, not only in gardens where special provisions are made for orchids, but in those in which they have had to take their places in general collections of plants.

The Orchid Conference at South Kensington in 1885 gave a great impetus to the hybridisation of orchids, and the influence of the exhibitions held by the Royal Horticultural Society in the gardens of the Inner Temple during the past quarter of a century has not been less marked in extending their culture. The attractions of the newer hybrids have contributed materially to the popularity of orchids by stimulating an interest in the family as a whole. Orchids thriving under comparatively cool conditions have been an important factor in the extension of the cult. They are not only cheap to grow in consequence of the small amount of fire-heat they require, but they are relatively low in price. There may be among them varieties that will command from £500 to £1,000 per plant, but there are large numbers that can be bought at the same prices as those at which pelargoniums may be obtained, and offer no more difficulties in cultivation. A point of no small importance in this connection is the fact that hybrids of great beauty can be bought for quite moderate sums, and that, as a rule, hybrids have a more robust constitution than the specific and varietal forms, and are therefore more amenable to cultural conditions.

In taking a glance into the future of orchid cult nothing is seen that is otherwise than full of promise. It may be seen that hybrids and varietal forms bearing flowers of quite exceptional beauty will continue to receive the attention of wealthy amateurs. Not less clearly can it be seen that there will be a much greater extension of orchid culture among amateurs who have gardens of moderate dimensions with one, two, or three glass-houses, and want to have an entertaining hobby. It is indeed on the latter that the future of the cult will largely depend.

George Gordon.

NEW PLANTS AND FLOWERS.

ÆTHIONEMA ARMENUM WARLEY HYBRID.

A beautiful little alpine sub-shrub, suggestive of a small daisy and Daphne cneorum when seen from a little distance. Although the main branches droop and possibly become quite prostrate as they extend, the branches soon erect therefrom, and so make dense little bushes about six inches high, clothed with linear grey-green leaves, each growth carrying a head of lilac-coloured flowers. It is a stronger-growing and earlier-flowering plant than the typical A. armenum. A.M., R.H.S., April 29. Miss Willmott, V.M.H. (gardener, Mr. C. Fielder, V.M.H.), Warley Place, Great Warley, Essex.

ODONTOGLOSSUM AMABILE ZEUS.

A delightfully beautiful form of the hybrid between O. crispum and O. crispo-Harryanum. It has large, finely-formed flowers of the purest white ground colour, being blotched and spotted on the central area with soft rosy-crimson or red-purple. The white lip has a yellow crest and crimson-purple blotch. A.M., R.H.S., April 29. Lieut.-Colonel Sir George L. Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

PRIMULA LA LORRAINE.

M. Lemoine, of Nancy, has raised this primula by crossing P. cortusoides with P. Veitchi. The plant bears a strong likeness to P. Veitchi, but seems to flower more freely than that species, and to have lighter green leaves. The erect spikes carry rich rose-purple flowers, and their pose is suggestive of P. cortusoides. Each flower is 1¼ to 1½in. across, and has a very narrow yellow rim round the eye. If this proves hardy, it will be a most desirable plant for the rock garden, but at any rate it should be a most useful subject for the cool greenhouse. A.M., R.H.S., April 29. Mr. Maurice Prichard, Christchurch, Hants.

ROSE ERNA TESCHENDORFF.

A dwarf, double-flowered polyantha rose that promises well as a bedding variety. We were assured that the glowing crimson of the neat flowers does not burn under summer sunshine, and if this is so the rose has a fine future, because varieties that fade to a bluish-magenta under bright sunshine are not pleasing for massing. It makes a capital pot plant, and is rather taller and stronger-growing than Jessie, which is already a popular red polyantha variety. A.M., R.H.S., April 29. Mr. W. Profittlich, Twickenham.

WALLFLOWER PRIMROSE MONARCH.

Opinions were divided as to the merit of this wallflower. Some who saw it considered it a great advance, but others, and chiefly those who like the looser, lighter-habited varieties, could find nothing to admire in it. The variety is very sturdy, and has somewhat stiff, stock-like growths and spikes. The latter are large and dense, and the light yellow flowers are about two inches wide. A good bed of it would doubtless look very effective. A.M., R.H.S., April 29. Messrs. J. Ross and Son, Kelvedon.

DAFFODILS.

Venetia.—One of the most chaste and beautiful of daffodils, and one that was very greatly admired. It is a strong-growing, triandrus hybrid, the stout stems carrying, in most instances, a pair of semi-drooping, large-sized flowers of the purest whiteness. A lovely daffodil, and a fine free grower. A.M., R.H.S., April 29. Mr. W. B. Cranfield, Enfield Chase.

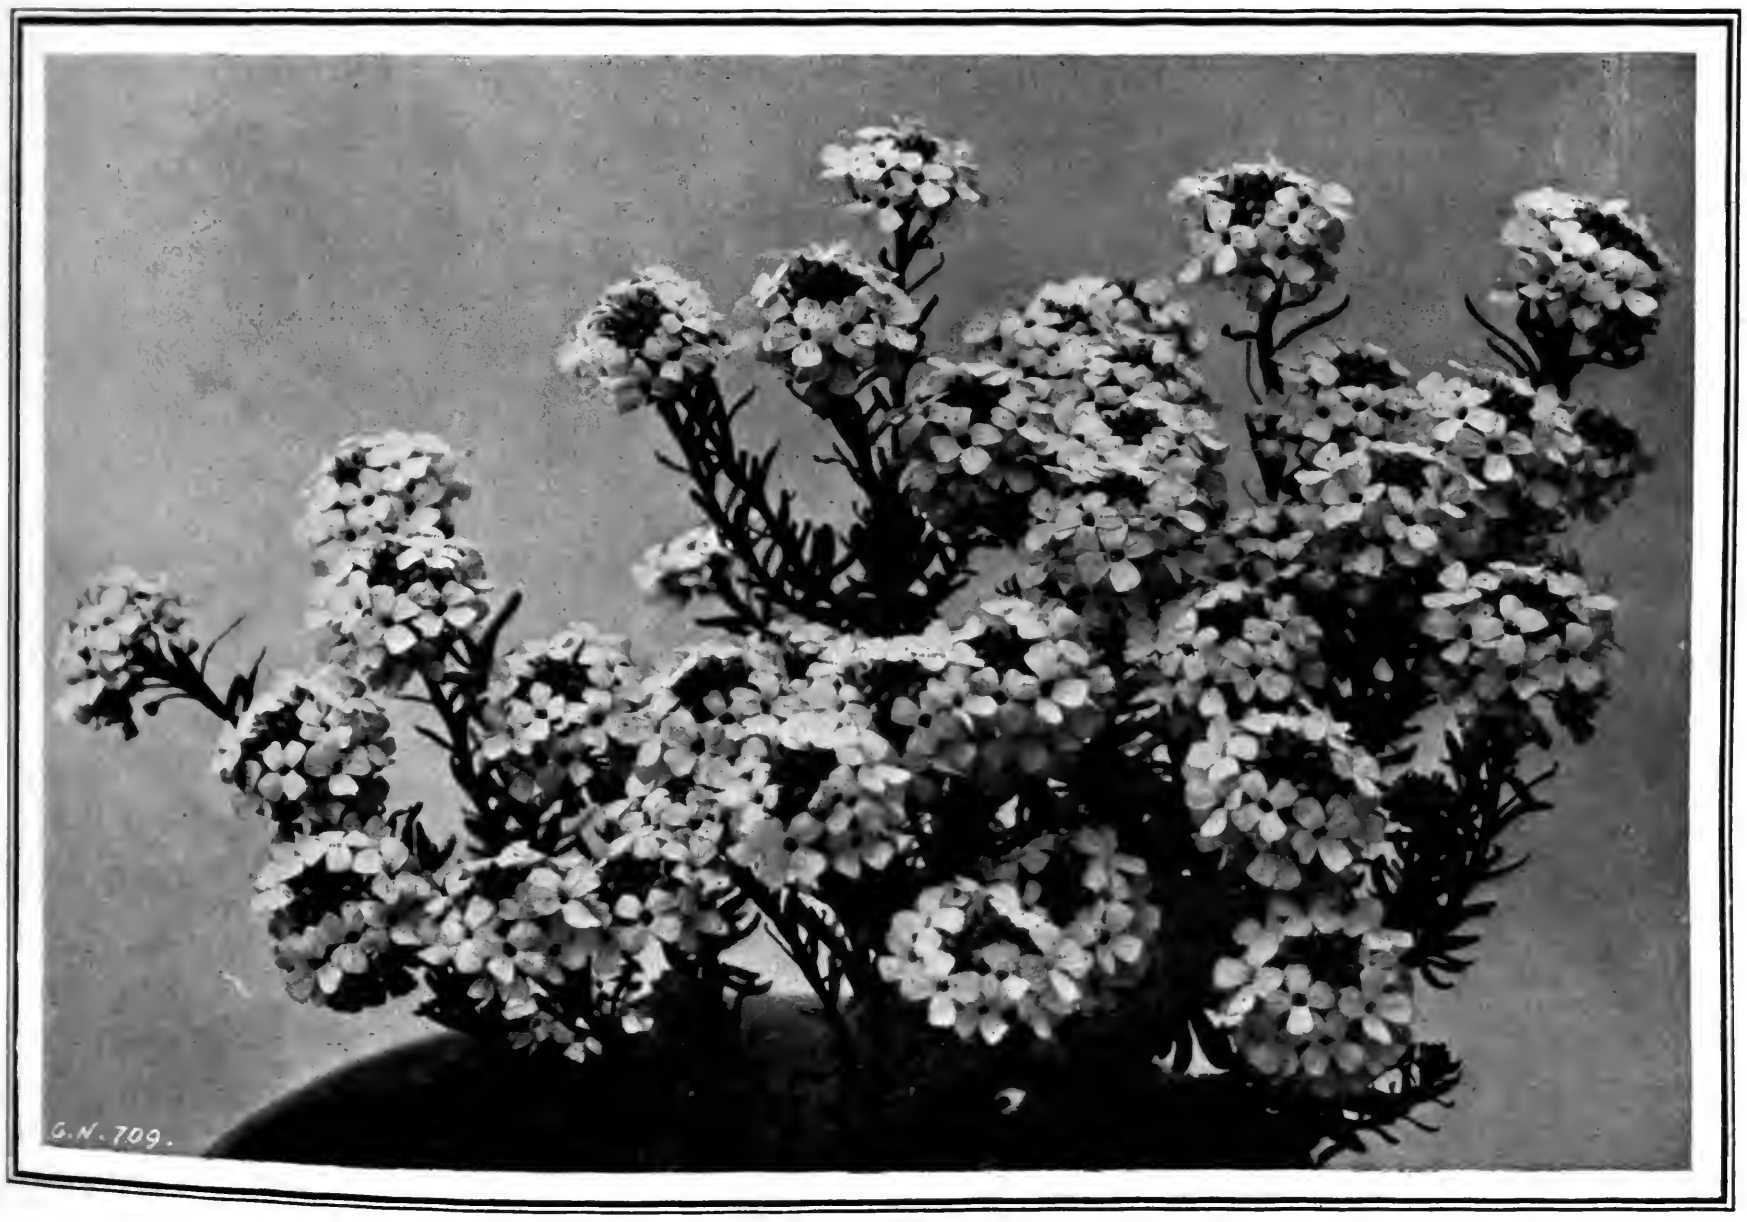
Evangeline.—A large Leedsi variety of great merit and beauty. A strong grower, it carries its flowers well on long stems. The stout perianth segments overlap and are pure white. The neat cup or crown is very dainty and of the palest primrose tint. A.M., R.H.S., April 29. Mr. H. Phillips, Olton.

ROSES.

Madame Edouard Heriot.—This is the beautiful Pernetiana rose that excited so much comment at the International Exhibition at Chelsea in 1913, when it was exhibited by the raiser, M. Pernet-Ducher, and won the "Daily Mail" gold cup as the best new rose shown on that occasion. The buds when just expanding are like those of Lady Battersea in shape and pose, but their colour is rich orange-vermilion or orange-terra cotta; the fully-expanded blooms are deep pink, heavily flushed with salmon-orange. A brilliant rose, and apparently a strong grower and free bloomer. It is sweetly scented as well as very handsome and elegant. It should prove a grand rose for floral decorations. Gold Medal, N.R.S., May 1. Messrs. G. Beckwith and Son, Ware Road, Hoddesdon.

Lady Plymouth.—A showy H.T. rose, delicately scented, and with large, shapely flowers of considerable substance. The colour is soft light yellow with sulphur tinting in the half-opened blooms, and a creamy pink shading in the fully-opened flowers. Gold Medal, N.R.S., May 1. Messrs. Alex. Dickson and Sons, Newtownards.

Mrs. Forde.—A large and beautiful H.T. rose of strong growth, and apparently grand constitution. It is broad petalled, and yet makes up a neat and pointed centre. The colour is palest flesh, almost white, with a creamy shade at the base of each petal; sweetly scented. Gold Medal, N.R.S., May 1. Messrs. Alex. Dickson and Sons, Newtownards.



ÆTHIONEMA ARMENUM WARLEY HYBRID.

A pretty sub-shrubby alpine plant, with wing stems, clothed with narrow grey-green leaves, and carrying heads of lilac flowers. A.M., R.H.S., April 29. Miss Willmott, V.M.H., Warley Place, Great Warley.

Mrs. George Beckwith.—A glorious rich yellow, broad petalled, globular H.T. rose of good size and substance, and carried on fine stems erect over ample green, glossy, handsome leafage. At its best this probably has more orange in the yellow than on this occasion as it is a Pernetiana variety, raised by M. Pernet-Ducher. Silver-gilt Medal, N.R.S., May 1. Messrs. G. Beckwith and Son, Ware Road Nursery, Hoddesdon.

Willowmere.—A lovely Pernetiana rose, raised by M. J. Pernet-Ducher, Venissieux-les-Lyon, France. It is somewhat like the Lyon Rose, and is also suggestive of Madame Abel Chatenay. Just as it opens it has the rich salmon-orange shading seen in the former, but when it has been open it loses this bright hue, and become rich pink. Silver Medal, N.R.S., May 1. Messrs. G. Beckwith and Son, Ware Road, Hoddesdon.

CLERODENDRON BAKERI.

A promising stove flowering shrub, bearing large axillary cymes of white flowers. It is a strong growing species, with bold green leaves, and is a native of Tropical Africa. Bot. Mag., t. 8474.

RHODODENDRON SUB-LANCEOLATUM.

A fine and variable species, cultivated in Japan as the Chinese Azalea. It will probably prove hardy in the warmer districts of the United Kingdom, but greenhouse treatment, as in the case of Azalea indica, will prove successful. The flowers are very showy, three inches across, and reddish-salmon, with red-brown spots in the case of a selected and richly-hued form. R. sub-lanceolatum is from the Loo Choo Islands, and in this country it will, for garden purposes, rank as an azalea. Bot. Mag., t. 8478.

CYTISUS NIGRICANS.

A fairly well-known, free-flowering European shrub, that produces very erect racemes of small, light yellow flowers during July and August. It is a shrub that will stand hard pruning in the spring, as it flowers on the current season's growth. A useful hardy shrub. Bot. Mag., t. 8479.

HELIOTROPIUM ANCHUSÆFOLIUM.

This is an odourless heliotrope with funnel-shaped, violet flowers, borne in looser heads than occur in the garden forms of H. peruvianum. H. anchusæfolium has four-angled and hispid stems, and is hardier than H. peruvianum, as it flourishes out of doors at Kew if given protection during the winter. It is also a success at Warley Place. Bot. Mag., t. 8480.

AGAVE HAYNALDI.

A stemless Mexican species, with a rosette of about 80 leaves, a spread of 6ft., and a height of 4ft. The cylindrical spike rises over 20ft. high, and is carried on a stout peduncle 4½ft. high. The flowers are very numerous and yellowish-green. An interesting species for lovers of succulents. Bot. Mag., t. 8481.

CYTISUS DALLIMOREI.

Raised at Kew in 1900 by crossing C. scoparius Andreanus with the pollen of C. albus, C. Dallimorei is the first hybrid broom intentionally produced. So far it has been propagated by grafting upon the laburnum, and it is a good garden shrub, flowering in May. Of rather slender, erect growth, it attains a height of 6ft. when fully grown, and the long growths of the previous year are clothed with beautiful papilionaceous flowers. These have a pale purple standard, crimson wings, and a white, purple-tinted keel, C. Dallimorei has seeded, and the flowering of its seedlings is looked forward to with interest. Bot. Mag., t. 8482.

RUELLIA HARVEYANA.

A Mexican acantha, discovered at Tehuantepec in 1904. It is a trailing shrub of straggling habit, and grows well under cultivation with begonias and gloxinias. The flowers are about two inches across, pale lilac, sometimes white. Bot. Mag., t. 8485.

HARDY AQUATICS FOR PRESENT PLANTING.

Apart from its everyday use in garden routine, water plays an additional part in garden decoration, being an essential condition toward success with all moisture-loving plants, and the element that enables us to cultivate aquatics, with the presence of sunlight. So infinitely varied is the play of light and shadow upon its mirrored surface that it is not a matter for surprise that water has the power to attract and fascinate with a charm that is perennial.

It is not every estate that is fortunate enough to have natural means for satisfying this inward desire, for more often than otherwise some artificial arrangement must be devised to give expression to this distinctive feature. Only two substances are recognised in practice as giving an impervious lining for a water-containing area of any extent, and these are: well-puddled clay and cement concrete; the former is generally to be recommended where there is a good water supply, but the latter husbands a small supply to the best advantage.

Given natural means, such as a flooded area and a supply of water, there is scarcely any limit to ambition in water gardening. A really judicious arrangement of the margin, giving bold promontories, with corresponding recesses, that slope gently to the water edge, enables effective use to be made of quaint exotics like bamboos, gunneras, senecios, spiræas like gigantea, aruncus, palmata, and venusta, and astilbes like rivularis, Davidi, grandis, and the hybrids Ceres, Arendsi, Pink Pearl, and Salmon Queen; Artemisia lactiflora, Rodgersia podophylla, pinnata, and tabularis, rheums, lythrums, Arundo Donax macrophylla, and Saxifraga peltata; while the recesses lend themselves to broad groups of Primula rosea, P. Sieboldi, P. Sikkimensis, P. japonica, and P. pulverulenta, double marsh marigolds, funkias, dwarf astilbes like Silver Sheaf, chinensis, Queen Alexandra, Lemoinei, and New Rose, Myosotis palustris, semperflorens, Mimulus cupreus Brilliant, lemon, yellow, and orange trollius, Iris pseudo-acorus variegata, I. lævigata, and the giants I. aurea and I. gigantea.

Water lilies (nymphæas) are essentially the most harmonious complement for the water area, and should have lavish representation; Marliac's varieties for deep water and distant effect, as the growth is rampant, and the flowers of immense size. The varieties include albida, white; carnea, flesh; rosea, pink; chromatella, yellow; ignea, carmine-red; flammea, red-purple to crimson; and rubra punctata, a striking combination of mauve, purple, carmine, and orange. Nymphæa Gladstoni, white; Gloriosa, bright rose; Ellisiana, carmine-purple; Froebelli, rich crimson; W. Doogue, flesh-pink; Sanguinea, blood-red; W. Falconer, crimson and gold; and James Brydon, light pink, includes some of the best of new and old varieties that succeed in water two feet or more in depth. In shallow water the forms of Leydekeri and odorata give excellent results, and where there is only a depth of twelve inches of water Nymphæa pygmæa and its variety Helvola, with N. odorata minor, will succeed, as these are quite miniatures of the larger forms.

Around the margin, yet still in the water area, numerous fine sedges, grasses, and plants of a flowering character would be grouped. Sagittarias are conspicuous ornaments in this position; the arrow-headed leaves project boldly above the water, and the flowers are on erect spikes; the best is S. japonica fl. pl., with large double white flowers, that are less fugitive than the single forms; of the latter gracilis and variabilis are worthy of a place. Pontaderia cordata gives a somewhat similar foliage effect to the last, but the flowers, also on erect spikes, are a pretty shade of blue. Of this there is a form known as angustifolia that is less desirable than the type.

Ranunculus langua grandiflora, the giant yellow Water Buttercup, is an aggressive plant, but nevertheless one of great beauty. Where it can have space to develop free from restraint, the leafy stems and flowers stand boldly out of the water, and the golden blossoms are produced in myriads. Villarsia nymphoides is a floating plant, half water lily, half ranunculus, but it must be used with caution, as it spreads by underground stems in a most insidious way, and is difficult to eradicate when once established. The giant Water Dock is an effective plant, by way of contrast, the gigantic leaves stand clear of the water, and at certain seasons these are coloured a warm shade of purple. Orontium aquaticum also discloses great beauty in the leaves, which are of a luscious blue-green colour, while the flowers are golden-yellow, resembling an arum, but without the showy spathe.

Aponogeton distachya is a captivating subject, with flowers that are white, with jet black anthers and scented like hawthorn; it is essentially a plant for a position close at hand, where the eye can readily appreciate its beauty. Menyianthes trifoliata is a charming native for any shallow water, where it develops into broad masses, the mimic horse-chestnut-like spikes of blossom being rendered effective by the dark green three-lobed leaves. Butomus umbellatus, another choice native, delights to root in shallow water, although the green foliage and slender spikes, carrying the rich rose flowers in umbellate heads, stand three to four feet above the water. The Reed Mace Typha latifolia, and its variety angustifolia, are water plants that usually abound in the back-waters of rivers and in fen districts; they are coarse, rampant growers, and require using with restraint; the variety minima is quite dwarf, and is admirable among choicer plants, in any water garden scheme.

Good grasses available for the margin of water gardens include Carex japonica variegata, pendula, and Riparia variegata, Cyperus longus, Eulalia zebrina, Glyceria spectabilis variegata, Phalaris elegantissima, Arundo Donax macrophylla glauca, and for ordinary soil upon the banks, Arundo conspicua, Elymus glauca, Pampas grass, and Stipa pinnata are meritorious grasses, either on account of the foliage or the inflorescence.

The planting of stream and water gardens is carried out to best advantage during the months of April and May, and in the case of nymphæas May is probably the best month of the year to move them with the minimum of loss. Wherever possible the plants should be introduced directly into mounds of soil or mud, taking care to eradicate all native growth of an undesirable character before planting choice subjects. When it is impracticable to introduce plants in this way nymphæas and other subjects may be planted in baskets made of wicker or reed, and filled with soil, and if floated out to the desired position and allowed to sink, the plants will eventually establish themselves in the mud; and, after this, little attention is necessary. In the case of nymphæas, the crowns occasionally require reduction in numbers, while the more vigorous aquatics will require restraint when they overrun their prescribed area.

Thomas Smith.

Coombe Court Gardens.

CARNATION NOTES.

Just at the present time, when the perpetual carnations are thoroughly making up for any failings they may have shown during the dull months, there is much to interest the grower who is of an observant turn of mind. Spring-time seems to be the one period of the year when the private grower of carnations is especially hard pressed, and, with the insistent calls for attention from a thousand and one differing subjects, and the extremely rapid growth made at this season by the perpetual carnations, many will find it a very difficult matter to keep in touch with this special subject.

To those who hold that perfection has been practically reached in carnations, may I say "the end is not yet"? The perfect carnation is not yet existent, grand as some of the varieties are, and I, for one, am convinced that the next few years will again chronicle progress. The greatest improvements of the last few seasons have undoubtedly been in the flower of the carnation. We have gained in size and colour, and perhaps also in form. But have we gained in the habit, stability, and continuity of the plant? Or in fragrance? This matter of habit is very important. Herein lies the great drawback to so many varieties. They lack what Mr. F. Dorner so aptly characterised as "the ever-blooming habit." For a carnation to be perpetual is not enough; we have to ensure that free, light habit which does not waste itself upon the production of innumerable side growths, but, breaking quickly from each stopped growth, goes straight away to blossom.

If I may explain a little, may I say that Harlowarden and Andrew Carnegie are of this type of growth, but they are not perfect. My ideal in habit is Pink Elegance, but this variety is not large enough to satisfy the novelty seekers, and for continuity, clean quick stem growth, and erect light habit, it is a model plant. Could we secure the attributes of the best blossoms of the Enchantress group, and retain for them the stems and quickness of Pink Elegance, I believe a great advance would be made.

A notable carnation has recently been on view in Chicago; this variety, a new seedling red, raised by Mr. H. Roth, of Lafayette, has a diameter of five inches. The stem and calyx appear to be satisfactory in every way, and the blossoms are moderately fragrant. As yet unnamed, this variety will be closely noted in the near future. From Pennsylvania comes the new Scarlet Wonder; this is likely to meet with a good reception, for, in addition to fair size, rich colouring, and good stems, it promises to be decidedly free.

Another new seedling, Laura Weber, is of the Enchantress type. It is very similar in hue, and possesses good stems, and is reported as an advance upon the old favourite. Soon we shall have the claims of Princess Dagmar brought before us. This variety is awakening considerable interest, and, after a round of showing, it will be put upon the market in a few months' time. Commodore, noted in THE GARDENERS' MAGAZINE of March 22, is still receiving much attention, and doubtless this useful seedling from Beacon crossed with Victory will be given a trial by many English growers.

I have been greatly interested in an account of some of the newer carnations from an expert American's point of view. Delhi, a new scarlet, is regarded as an advance upon Beacon in every way, except in the petals, which are somewhat rough, and inclined to curl; otherwise the report has it that the colour is better, and it is a freer variety to blossom. The same grower speaks enthusiastically of Comfort, and, to back up his opinion, is growing ten thousand of it this season. It is stated to be the most productive red for the cut flower grower, but the blossoms are hardly up to the high quality of the new Scarlet Wonder.

Rosette has a good name in the States, being of good quality, with stiff stems, and of free and strong growth. Cuttings of this variety root easily, and the colour is very lasting. Gloriosa, highly regarded by some of our English growers, is getting rather a mixed reception. Some growers are giving it up entirely, while others seem to manage it splendidly, and are increasing their stocks.

Florists in San Francisco are remarking upon the good qualities of an unnamed seedling, which was raised and sent in to market by a Japanese grower. The flowers are large, substantial in build, with good stems, and a bright rosy-cerise colouring.

Young stock is growing apace, both seedlings and cuttings. The former are allowed to get away to flower as quickly as possible, in order that the first survey of the blossoms may be made, and inferior forms weeded out before the other plants from cuttings commence their season of flowering. Cleanliness is very essential, and watering must be closely attended to now, as growth is so rapid, and pot plants quickly dry during sunny days.

Light shading is necessary for plants flowering under glass during fierce sunlight, but for young stuff the maximum of light and air is essential.

P. S. HAYWARD.

ANEMONE NEMOROSA GRANDIFLORA.

In the large-flowered Wood Anemone, Anemone nemorosa grandiflora, we find a capital garden plant for shady or half-shady places, although it can also be cultivated successfully in the sun. It is best described as a form of the common wood anemone, glorified in all its parts. It is taller, has bolder and more handsome, though equally graceful flowers, and considerably larger and broader segmented blooms. A free bloomer, and giving a number of its handsome white flowers, it is a splendid thing for the border or the base of the rockery in April and May. It can be grown well in almost any soil, but prefers one which is not too stiff and heavy. Tubers may be bought in autumn, and planted, whenever procured, about two inches deep, although a little less depth is preferable in stiff soils. Plants can sometimes be purchased in pots, and planted out at any time without disturbing the roots.

S. ARNOTT.

BROWALLIA VISCOSA.

Since the introduction of Browallia speciosa major, which so quickly became popular, increased attention has been devoted to some of the other species. Among these is B. elata, which has been referred to as the forget-me-not of the Andes; and that at the head of this note, which is now flowering freely. It possesses the great merit of flowering continuously nearly throughout the year. Last summer it was very effective when bedded out; then, during the autumn and winter, numerous examples were shown at the meetings of the Royal Horticultural Society, and now a group of it makes a bright feature in the warm greenhouse. From the better-known Browallia speciosa major it differs in the flowers being smaller and of a deeper and richer blue, with a conspicuous white eye. It is of a perennial nature, and can be readily increased by cuttings, though the Century Supplement of the "Dictionary of Gardening" states it is a half-hardy annual. According to the same authority, B. Czerwiakowski and B. pulchella are synonyms of B. viscosa. T.

ERICA CARNEA.

The Alpine Forest Heath is one of the most delightful spring flowering subjects, and is seen to advantage when planted in large masses on sloping ground. It is a native of Central Europe, where it luxuriates on the mountain ranges, and creates bright patches of colour amongst the snow early in the year. In this country it commences to blossom in January, and its rich rosy-pink flowers continue bright and attractive until the end of April. The variety alba is also worthy of inclusion.

E. carnea is particularly hardy and of easy culture, as it grows and flowers freely in heavy loamy soil. In these gardens there are two acres of this lovely heath naturalised on the hillside, and it is perfectly at home in our heavy retentive soil. It is sometimes recommended to clip it back after flowering, but this has been tried, and the plants were found to blossom less freely as a result. It is naturally bushy and compact in growth, so that no good object can well be attained by clipping.

When preparing heavy ground for its reception, it is an advantage to incorporate some leaf-soil, and any other suitable material that may be available. The best time to plant is from October to January, after the flower-buds are formed, and as the work proceeds press the soil very firmly around the roots. The subsequent treatment consists in keeping the plants free from weeds until, in time, they themselves cover the whole surface, and prevent weeds from growing. This species is easily propagated by division, large roots being pulled apart, and the separate pieces planted with a portion of root attached.

We have found that bulbs naturalised in large breadths of this heath help to enhance the effect and lend diversity to the arrangement. Narcissus Mrs. Langtry is a lovely variety for this purpose, the creamy tinge of the flowers toning beautifully with the blossoms of the heath during April. Another good narcissus for the purpose is Waterwitch, a delightful variety for naturalising, but, owing to its drooping flower-heads, it is seen to the best advantage on rising ground. Anemone apennina (the blue Wood Anemone) makes a charming contrast when intermixed in irregular drifts, and the effect is so delightful that it must be seen to be fully realised.

J. GARDNER.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

SEEDLINGS.—Seeds sown during the late summer and autumn of last year, and some of the early sowings of the present year, will have developed into seedlings of a size that will require pricking off into store pots, or singly, as the case may merit. We generally find that young plants left in the seed beds after they have developed their first leaf and the first root makes its appearance, become more or less retarded in growth, and, as it is not desirable to run any risk of delay, it is advisable to deal with the young plants as soon as the new root makes its appearance. The amount of pot room afforded to young seedlings generally depends on the amount of storage space available for their accommodation. Where it becomes a question of room it is desirable, perhaps, to prick off several together in 3in. or 4in. pots or shallow pans. Where plenty of room is available the sooner a plant can be potted singly the better. All young plants do not possess the same vigour, hence the desirability of separate pots. This applies to cattleyas and the epiphytal kinds generally. We find a suitable compost in finely-chopped peat and sphagnum moss, with sufficient sand and finely-broken charcoal to render the compost porous. The pots used should be clean and drained to about two-thirds their depth with clean broken crocks. Advanced seedlings, say, of one year and upwards, of the epiphytal kinds may now have attention; use a coarser compost as the plants become stronger and require larger pots.

TERRESTRIAL KINDS, such as cypripediums, cymbidiums, calanthes, phaius, etc., make rapid progress directly after germination. If we take cypripediums alone some kinds germinate almost immediately after sowing, and others remain in a dormant state for months. These are all best treated singly as soon as they can be safely transferred from the seed bed to the small pots, but it is always best to have the first root developing before removal. This enables the roots to push into the new compost with the least possible check. For the whole of this section we find that a small proportion of good fibrous loam is an advantage, intermixed with the before-mentioned potting compost.

SEEDLING CALANTHES AND PHAIUS, raised from seeds sown last year, will now show signs of restarting into growth. In the case of calanthes the young plants make considerable advance if given suitable encouragement the second year. It is desirable that they should be potted singly, using small pots, and, after a certain stage of growth and rooting activity, they may be transferred to larger pots. The result of this encouragement often induces the plants to produce flowers at the end of the second year's growth. — H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

THYRSACANTHUS RUTILANS. — If pruned as recommended after flowering, these plants will now be producing numerous side growths, which may be taken with a slight heel of the old wood, and inserted as cuttings in a fairly sandy compost. They will soon root if kept close, moist, and shaded. When ready put them singly in small pots, eventually transferring the largest into 32's, and the smaller plants into 48's, growing on fairly fast. A suitable compost is one consisting of good light loam, with the addition of a little leaf-mould, well-decomposed manure, and sand. Good drainage is essential, for as the plants become pot-bound liberal supplies of water will be necessary. At this stage an occasional application of an approved fertiliser will materially assist them. In the early months of the year a batch of this graceful plant, with its long, pendulous racemes of scarlet, tubular flowers, is very pleasing. Its worst enemy is perhaps brown scale, and for this the plants should be examined occasionally, and kept clean with the aid of a small soft brush, and an approved insecticide.

ISOLOMA HIRSUTUM is a very pretty gesnerad not frequently met with, but worthy of cultivation in small quantity. Old plants may have their tops reduced, be shaken out of the pots and repotted, or cuttings of the new growths may be taken; they are easily rooted, and in a season make good-sized plants in five or six-inch pots. Soil and treatment as usually afforded gesneras will be found suitable.

CALADIUMS.—The small-growing forms, as C. argyrites and C. minus erubescens, though making very pretty plants in small pots, are perhaps seen at their best when grown in 54's and 48's. A few of the best plants may now be selected for this purpose. The larger varieties now becoming established in their final pots should be given plenty of room to allow them to attain full development. Ventilate on all possible occasions, and lightly shade only when necessary to induce coloration and induce firmness in the foliage, always maintaining a moist atmosphere by frequently damping down.

STOVE CLIMBERS. — Rapidly-growing stove climbers will now require frequent attention, if they are not to be allowed to become a mass of tangled growths. As far as possible keep each growth to its own string or wire. Should mealy bug or other insect pest be present endeavour to keep it down by means of sponging. This advice applies especially to such plants as stephanotis, Hoya carnosa, passifloras, and Hexacentris mysorensis, the latter now commencing to bloom will continue for some weeks a pleasing object if a good rooting space and plenty of trellis or roof room can be allowed for its development. Allamandas and dipladenias will also need attention, and should be tied down as becomes necessary.—H. Prime, Hatfield House Gardens.

FRUITS UNDER GLASS.

EARLY PEACHES.—The fruits in the earliest house will now be gathered, or nearly so. Where this is the case syringe the trees well night and morning to keep the foliage clean and healthy, and give the borders a thorough soaking of water, and avoid an arid atmosphere, as the latter is not conducive to thorough ripening of the wood. Keep the ventilators wide open day and night, and at the end of the month, where the lights are removable, these may be taken off and any necessary repairs be made. Trees in houses where the fruits are approaching ripeness should receive a thorough soaking with clear water, giving no more until the fruits are gathered. Put aside any leaves which shade the fruits, to fully expose them to light and ensure their being high-coloured and well-finished. Discontinue the use of the syringe on ripening fruits, also lessen the atmospheric moisture, gradually increasing the quantity of air by leaving the top and bottom ventilators partially open at night, at the same time using a little artificial heat, especially should cold winds prevail. By these means good-flavoured fruits are obtained.

SUCCESSIONAL PEACH HOUSES.—These trees must receive regular attention in disbudding, tying of the shoots and thinning of the fruits. Remove every shoot which is not required for fruit-bearing or furnishing the trees, and so give the wood that is left a chance to become well ripened. Apply liquid manure and quick-acting artificials to trees swelling their fruits, especially in the case of old trees, as where the drainage is good there is little or no danger of watering being overdone. Thoroughly syringe the trees night and morning with soft water, and fumigate at once if greenfly should appear.

STRAWBERRIES.—To secure fruit of the finest flavour the plants must receive abundance of air and a cool atmosphere for a few days after they are coloured. Continue to bring forward successional plants as the earlier ones are cleared out, and give copious syringings, and daily applications of weak liquid manure until the fruits change colour, also pay attention to early thinning of the fruits. Where it is intended to plant out forced plants some rough protection is necessary for a few days, or they will receive a severe check from which they take a considerable time to recover.—F. Jordan, Warter Priory, York.

THE FLOWER GARDEN.

GENERAL WORK. — Every opportunity should be taken to forward as much as possible all work of the general routine character, in view of summer bedding operations. At this season lawn mowing and the grass edgings to paths and borders require more attention than at any other, and unless the work is kept well in hand it proves very troublesome during bedding-out time, especially where labour is none too plentiful. The occupants of herbaceous borders are greatly benefited by frequently hoeing between them; this procedure not only kills weeds, but it prevents the soil becoming baked and hard during hot weather. Such subjects as pæonies and delphiniums should be given occasional waterings with liquid manure whenever practicable, as this has a marked effect on the development of the flowers.

THE ROCK GARDEN, which is very attractive at the present time, with a great variety of plants in flower, must be kept free from weeds, which now develop very quickly if left only for a short time, and soon impoverish the soil, for, when they are allowed to establish themselves, they cannot be rooted out without disturbing the roots of the rock plants. As the different subjects pass out of flower, and time permits, the dead flowers should be removed; this imparts a tidy appearance to the rockery, and is helpful to the plants, especially the most delicate ones.

ATTACKS OF GREENFLY are already becoming troublesome among roses, especially so with the members of the rambling class. The pest must be eradicated by spraying with quassia extract, or some other reliable wash. A sharp lookout should be kept for the leaf-curling grub, which usually puts in its appearance a little later on, and so soon disfigures the foliage and flowers, if allowed to remain. Hand-picking seems to be the most effective means of getting rid of this pest, it being difficult to reach by spraying.

BEDDING PLANTS.—No trouble should be spared in the process of hardening-off of these subjects, and this requires to be done in a gradual and thorough manner, otherwise severe checks to the plants will result. Those which have been brought along quickly in a moist, close atmosphere will require the most care in this respect, their foliage naturally being very tender, and if exposed too suddenly to the air and the sun's rays they will become severely checked. Large specimen plants of fuchsias, heliotropes, etc., after being subjected to full ventilation before removal to the open, sometimes suffer when exposed, but I find, by standing them in a sheltered position for a few days with a double thickness of netting drawn over a light framework, there is no fear of harm, and their hardening-off is completed. —T. B. Field, Wych Cross Place Gardens.

ROYAL SHOW

BRISTOL,
July 1st to 5th, 1913.

THE ANNUAL EXHIBITION of HORSES, CATTLE, SHEEP, PIGS, POULTRY and FARM PRODUCE; JUMPING, HORSE-SHOEING and BUTTER-MAKING COMPETITIONS, AGRICULTURAL EDUCATION, FORESTRY and HORTICULTURE.

HORTICULTURE
ENTRIES CLOSE MAY 31st
Live Stock entries close May 20th).

Prize Sheets and Entry Forms will be forwarded on application to
THOMAS McROW, Secretary.
ROYAL AGRICULTURAL SOCIETY OF ENGLAND,
16, Bedford Square, London, W.C.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

National Rose Society.

The first spring show ever held by this progressive society was a very great success, so much so that steps have already been taken to repeat the effort in 1914. Roses did not fill the Royal Horticultural Hall to overflowing on the First of May, but there were plenty of the most lovely flowers and finely-grown plants, and, though there seemed to be abundant room for visitors, the great hall was inconveniently packed all through the day, and the poor pressmen had no easy task to record the competition. Could not judging commence as easily at 10.30 as at 11? This would give officials and pressmen an extra half-hour, which the latter would greatly appreciate, and the former would be able to place the medal cards as well as the prize cups upon the successful exhibits.

About twelve o'clock, when the show was opened, there was a solid queue of people along the side of Vincent Square, waiting for admission. New roses were a fine feature, and three gold, one silver-gilt, and one silver medals were awarded.

NEW ROSES.

First prize for a dozen blooms of new roses, distinct, was won by Messrs. Alex. Dickson and Sons, Newtownards, with Mrs. Wilfred Lloyd, Mrs. Forde, Mrs. Foley Hobbs, Mabel Drew, George Dickson, Lady Ashtown, Duchess of Sutherland, Melody, C. F. Cowan, Alex. Hill Gray (rich yellow), Lady Derryham, and Mrs. Cornwallis West, white. The Floral Committee of the N.R.S. made the following awards to new roses (for full description, see "New Plants and Flowers," p. 339).

Gold Medal.—To Mdme. Edouard Heriot, raised by M. J. Pernet-Ducher, and shown by Messrs. G. Beckwith and Son, Hoddesdon. To Mrs. Forde and to Lady Plymouth, both from Messrs. Alex. Dickson and Sons, Newtownards.

Silver-gilt Medal.—To Mrs. George Beckwith, raised by M. J. Pernet-Ducher, and shown by Messrs. G. Beckwith and Son, Hoddesdon.

Silver Medal.—To Willowmere, raised by M. J. Pernet-Ducher, and shown by Messrs. G. Beckwith and Son, Hoddesdon.

NURSERYMEN.

In the large class for a group of pot roses to occupy a space not exceeding 250 sq. ft., there were two competitors, and each put up a large corner exhibit of considerable beauty. Premier award was made in favour of Messrs. Paul and Son, Cheshunt, this firm staging tall weeping standards of Lady Gay, Minnehaha, the new white Cuckoo's Mate, a single musk rose, Dorothy Perkins, Sodonia, Excelsa, and Milky Way, these being placed over bush plants of Frau Karl Druschki, the lovely pink Mdme. E. Metz, the white Magnolia, the deep velvety red Othello, Edward Mawley, and J. B. Clark. The arrangement was good, and the whole was edged with maidenhair fern. Messrs. Hobbies, Lim., Dereham, won the second prize with a capital lot of Wichuraiana varieties, but a trifle crowded; Mr. Chas. Turner third.

For a combination of pot and cut roses arranged on a space of 100 sq. ft., Messrs. A. J. and C. Allen, Bowthorpe Nurseries, Earlham, Norwich, secured the first prize. This firm had the Orleans rose for a ground work, with a small group of Sunburst, and over these were beautiful standards of Dorothy Perkins, White Dorothy, Coquina, Excelsa, Lady Godiva, and Minnehaha. Messrs. B. R. Cant and Sons, Colchester, came second, and they had delightful freely-flowered examples of Goldfinch and a fine stand of the brilliant Austrian Yellow. Messrs. W. Cutbush and Son, Highgate, third, with a pretty group of dwarf polyantha roses.

Messrs. G. Mount and Sons, Lim., Canterbury, gained a first for a group of cut roses, 20ft. by 3ft., and everyone was loud in praise of the splendid groupings of glorious flowers of Mrs. John Laing, Richmond, Mdme. Abel Chatenay, Frau Karl Druschki, Captain Hayward, Sunburst, and Ulrich Brunner. Mr. G. Prince, Longworth, was placed equal first with the contesting firm, and his special feature was an arched background of the various rambler roses and a stand of Mrs. Longworth; Messrs. B. R. Cant and Son, Colchester, third.

Messrs. Paul and Son, Cheshunt, were placed first for eighteen standard roses in pots, in not fewer than a dozen varieties; these were worked on the Rosite stock, and carried fine blooms and splendid foliage. The leading varieties were Eugène Boullet, Mrs. J. Laing, Richmond, Viscount Enfield, Laurent Carle, Gloire Lyonnaise, Dean Hole, Mrs. S. G. Crawford, A. R. Goodwin, Lyon Rose, Hugh Dickson, and Frau Karl Druschki. Mr. Chas. Turner, Slough, came second. There was only one competitor in the class for nine weeping standard roses, and this was Messrs. Paul and Son, Cheshunt, who had quite good examples of Eisenach, Sodonia, Hiawatha, Lady Gay, White Dorothy, Excelsa, Mdme. Casimer Moulle, Minnehaha, Lady Godiva.

Fifty dwarf polyantha roses in pots made an interesting class, in which Messrs. Paul and Son, Cheshunt, were to the front with such varieties as Mrs. Cutbush, Mdme. N. Levavaseur, Maman Levavasseur, Aschenbrodel and Jeanne d'Arc. Mr. Chas. Turner, Slough, came second. In neither of the groups were the plants at their best, as there were heaps of unopened buds and comparatively fewer expanded flowers.

A first prize fell to Messrs. Alex. Dickson and Sons, and this was in the class for nine pots of new roses. Strong plants, carrying grand flowers, were submitted, and the varieties were Mrs. J. Campbell Hall, Melody (yellow), Mrs. Foley Hobbs, the lovely white Mrs. Cornwallis West, and Mrs. Forde, a grand H.T. rose, white, faintly tinted flesh.

Cut flowers were in excellent condition, and first prize for three dozen flowers in not less than twenty-four varieties was won by Messrs. B. R. Cant and Sons, Colchester; this firm had lovely blooms of Ulrich Brunner, Mrs. E. Mawley, Mdme Melanie Soupert, Frau Karl Druschki, Elizabeth, Maman Cochet, Wm. Shean, Florence Pemberton, Dean Hole, and The Bride.

Messrs. Alex. Dickson and Sons, Newtownards, co. Down, gained a first prize for eighteen blooms in not less than a dozen varieties, with a box of light-hued blooms, some of the best being Sunburst, Mrs. Foley Hobbs, Mary Greer, and Mrs. Cornwallis West. Messrs. G. Mount and Sons came second with a fine set, in which Sunburst, F. K. Druschki, and Liberty were very fine.

Messrs. G. Mount and Sons, Canterbury, put up a lovely dozen vases of roses, seven stems of each, and won first prize with their display; the varieties disposed were S. M. Rodocanachi, Caroline Testout, Mrs. H. Stevens, Captain Hayward, Mdme. Abel Chatenay, Frau Karl Druschki, Sunburst, Ulrich Brunner, Richmond, Mrs. J. Laing, Molly S. Crawford, and Liberty. Mr. Will Tayler, Hampton, scored for six vases of roses, and his varieties were Mrs. R. G. Sharman Crawford, Mrs. J. Laing, Capt. Hayward, Frau Karl Druschki, La France, and Caroline Testout.

Messrs. G. Mount and Son staged a fine five baskets of blooms, and won a first prize with long-stemmed specimens of Mrs. J. Laing, Capt. Hayward, Mdme. Abel Chatenay, Richmond, and Sunburst.

AMATEURS.

Mr. Jas. Brown, Longfield, Heaton Mersey, won many prizes, but none so splendidly as that for a group of pot roses occupying a space not exceeding 40 sq. ft. To the first prize a gold medal was awarded. The group was a fine one, the plants all well grown and set up in good style. To bring such fine roses from so great a distance was a considerable feat, and we congratulate Mr. J. Brown upon his pluck, his fine culture, and his gold medal. His Frau Karl Druschki, Ulrich Brunner, Capt. Hayward, Dorothy Perkins, and Mrs. J. Laing were lovely.

Mr. C. S. Gordon Clark, Fetcham Lodge, Leatherhead, was easily first for a group of cut roses set out on a space 4ft. by 3ft., and his was a charming little collection of Blush Rambler, Joseph Lowe, Antoine Rivoire, W. A. Richardson, Richmond, Sunburst, Lady Hillingdon, etc.; a silver-gilt medal was worthily awarded in this case in addition to the first prize. Mr. R. H. Darlington, Park House, Potters Bar, came second, and set up capital flowers of Pharisaer, Innocence, Richmond, Ulrich Brunner, and Caroline Testout; Mr. J. Brown, Heaton Mersey, third. For a dozen exhibition blooms, Mr. J. Brown, Heaton Mersey, secured a first prize, and had no competitors; he had F. K. Druschki, Lyon Rose, Mdme. de Watteville, Mrs. J. Laing, Dean Hole, and Mdme. Abel Chatenay.

Mr. H. R. Darlington had the best six cut blooms, winning with good flowers of Souv. de Pres. Carnot, F. K. Druschki, Dean Hole, Molly Sharman Crawford, Bridesmaid, and The Bride. Dr. E. P. Smith, Witham Place, Boston, second, with Mdme. Melanie Soupert and Antoine Rivoire in fine form; Mr. P. T. Davis, North Warners, Burgess Hill, third. Frau Karl Druschki was the rose that won for Mr. C. S. Gordon Clark the premier award for six blooms of one rose.

Mr. James Brown led for six vases of roses, and showed Frau Karl Druschki, Liberty, Richmond, etc.; Mr. C. S. Gordon Clark second, his Sunburst and Richmond being very good. A first prize and silver medal was awarded Mr. Conway Jones, Hucclecote, Gloucester, for a basket of Anna Olivier, and Mr. James Brown, Longfield, Heaton Mersey, was a capital second with beautiful blooms of Frau Karl Druschki.

LADIES.

The best table decoration of roses was the effort of Mrs. A. Robinson, Norhyrst, Carshalton, who displayed medium-sized blooms of Mdme. Abel Chatenay lightly, with a few sprays of asparagus. Mrs. A. W. Ruff, Sharnbrook, Beds, came second with a good design in Mdme. Abel Chatenay roses, and Mrs. A. E. Brown, Brookes Lodge, Reigate, came third with a pretty design of Sunburst. There were seven entries.

The premier vase of roses set up by a lady was of Richmond, and Miss M. E. West, Firth Dene, Reigate, was the winner; Mrs. Courtney Page, Ridgeway, Enfield, came second with Sunburst; and Mrs. J. Bide, Cowley, Uxbridge, third with Richmond. There were eight entries.

United Horticultural Benefit and Provident Society.

The adjourned annual meeting of this society was held at the Royal Horticultural Hall, Westminster, on Monday, May 5, at 8 p.m. There was an excellent attendance, over which Mr. Chas. H. Curtis presided.

After the usual formalities had been disposed of, the report of the committee for 1912 and the accounts for the year were presented, and these are given in abridged form:

REPORT OF THE COMMITTEE FOR 1912.

The net number of members is 1,874; and the following table shows the additions made during each month: February (1912), 5; March, 0; April, 0; May, 1; June, 13; July, 205; August, 93; September, 36; October, 136; November, 57; December, 7; January (1913), 5; making a total additional membership of 558. Of this number, 62 have joined on the State side only; while 398 are ordinary or voluntary members only.

The number of lapsed members is 43, nineteen being from the higher scale and twenty-four from the lower. It is interesting to record that the following sums, standing in the name of members who have been lapsed for many years, and who have now reached the age of sixty, have been paid—viz., £9 16s. 7d.; £14 3s. 4d.; £21 2s. 5d.; and £26 14s. 2d.

Five members have died during the year, one who joined the society on September 9, 1907, and whose young widow received assistance at a very critical time from the society's Benevolent Fund; and others who left sums as follows: £39 17s. 6d.; £29 18s. 5d.; £62 4s. 4d.; £10 13s. 11d.; £5 15s. 10d. The total amount paid out to the nominees of deceased members was £148 10s.

The total amount of sick pay to benefit members during the year was £588 18s. 10d., as against £507 12s., an increase of £81 6s. 10d., but only £27 8s. 4d. more than two years ago. The chronic sick pay amounted to £95 9s. 6d. The total payments to the Benefit Fund were £2,194 0s. 2d., and the disbursements £1.400 7s. 2d. Several members who reached the age of seventy years withdrew from their deposit, under par. 4 of rule xviii., leaving £10 in the funds to be paid to their nominees. One member, who joined in 1869, withdrew £130 5s. 2d.; another withdrew £61 7s. 7d., leaving £100 still to his credit; a third, £39 9s. 11d.; and a fourth, £23 2s.

Subscriptions to the Benevolent Fund amounted to £232 3s. 4d., and the payments therefrom to £108 5s. 3d. (against £90 11s. 6d. in 1911); these including the sums regularly paid to several members over seventy years of age, as well as a few grants made to members or members' widows in great distress.

The strictest economy, consistent with the proper working of the society, has been observed in the management. The total management charges amounted to £418 0s. 7d., as against £222 7s. 6d. in 1911, and £222 9s. 7d. in 1910. But a sum of £128 16s. is recoverable from the Insurance Act Commissioners for administration expenses incurred on the State side of the society's business. The expenses for the ordinary business were therefore £289 4s. 7d. In April the new ledgers referred to in last year's report were opened, and every balance from the old ledgers was transferred and checked by the auditors, it having been seven years since the work was necessary.

The repeated suggestions to the members that those who are recovering from an illness should take advantage of the provisions of the Convalescent Fund have been better acted upon in 1912 than in some previous years. The amount of assistance from this fund was £6 10s. and payments thereto £7 12s. 3d. N. N. Sherwood, Esq., founder of this fund, contributed five guineas as usual.

The report for last year alluded to the work of the committee in regard to the National Insurance Bill then before Parliament. Since this Bill became a law of the land, your committee had then to consider the advisability of making the society an Approved Society under the Act. The whole question was very cautiously and carefully proceeded with, six special committee meetings having been held, in addition to the ordinary monthly ones. A scheme had to be submitted for the sanction of the Insurance Commissioners, and fresh rules, in conformity with the model rules issued by the said Commissioners, had to be prepared, also new scales of sick pay for the ordinary side of the society's work. Actuarial advice was taken, and a delegate from the Insurance Commissioners attended at one of the committee meetings. Eventually, on June 17, 1912, a special general meeting of the members was called, and a resolution was then passed agreeing that approval should be sought and appointing a sub-committee to effect in the rules submitted such further amendments as might be found necessary by the Commissioners. The committee have fully carried out the terms of this resolution, and, as soon as this certificate was obtained, the committee proceeded to advertise the advantages of the society, and chose the media of the Horticultural Press. This resulted in a considerable accretion to the membership.

In future it will be necessary to hold two separate annual general business meetings, one for the ordinary membership business, the other for the State section.

The committee, collectively, particularly desire to record their appreciation of the services of Mr. C. F. Harding and Mr. A. C. Hill in connection with the drafting of the new rules and tables of benefits. Mr. Harding's consistent assiduity deserves the warmest commendation.

The investments made by the trustees during the year are as follows: £800 (New) Queensland 3¾ per cent.; £500 Queensland 4 per cent., and £1,200 London and South Western Railway 3½ per cent., a total of £2,500, the purchase price for same being £2,333 15s.

Owing to advancing years, and the heavy increase of clerical work that the business of the society now entails, the committee had reluctantly to accept the resignation from the secretaryship of Mr. William Collins, who celebrated his semi-jubilee in that office on February 12, 1912. Mr. Collins' services as secretary terminated upon September 9, 1912, but during the interim he has assisted Mr. A. C. Hill, whose appointment as secretary, pro. tem., was agreed to at the August meeting. The committee desire to record their expression of the high respect in which Mr. Collins is held, of his unvarying courtesy, ever-willing service, and close application to his duties.

Mr. Curtis reviewed the work of the society at some length, and moved the adoption of report and accounts. Mr. J. Harrison Dick seconded the motion. Mr. J. Weathers paid tribute to the excellent management of the society, and expressed wonder that such an excellent institution should have so comparatively few members, remembering what great advantages it offers. He pointed out that as the society's invested funds were all put in the balance-sheet at par value, it was likely to give a rather false idea of their value. There was about £3 surplus assets over liabilities, as shown; but if the investments were quoted at market price instead of par value, the balance-sheet would show about £3,000 on the wrong side. The Chairman pointed out that all the investments had been purchased well below par, and all were redeemable at par, and only in the extraordinary contingency of having to hurriedly realise any of its investments would any loss accrue. He promised, however, that another year the purchase price, and also the market value of the investments, should be set out in the report. In answer to questions, the Chairman said that, in connection with the business under the Insurance Act, an annual meeting would be held in the autumn; accounts for the year would close at the end of July, and the meeting would be held as soon after as the Government audit was completed.

The motion was then put, and carried.

Mr. W. P. Thomson resigned the treasurership, owing to pressure of business, after six years' hard work. He was heartily thanked and was unanimously granted £25 for special services rendered to the society from the management fund. Mr. Thos. Winter was elected treasurer in place of Mr. Thomson, and Mr. A. C. Hill was elected secretary in place of Mr. W. Collins, who has resigned after 25 years' service.

A delightful part of the proceedings was the presentation of a gold watch and chain and an illuminated address, to Mr. W. Collins, subscribed for by members and friends as an expression of regard and appreciation of 25 years' service as secretary. Mr. Curtis made the presentation on behalf of the members, and his kindly remarks evidently voiced the sentiments of the members, as they were heartily endorsed. Mr. Jas. Hudson and Mr. J. Wheeler added a few words, and Mr. Collins responded feelingly.

Votes of thanks were accorded the trustees, the committee, the Press, and the auditors, the latter being re-elected. The retiring members of the committee, Messrs. J. H. Dick, E. M. Wilson, D. Campbell, and C. Harding, were re-elected, and Mr. Thomson was elected to the seat vacant by the elevation of Mr. T. Winter. Mr. Oxtoby made several suggestions for further popularising the society, and a vote of thanks to the Chairman, moved by Mr. Frogbrook, brought the interesting and busy proceedings to a close after a sitting of nearly 2½ hours.

Midland Auricula and Primula Society.

APRIL 30.

The Midland section of the National Auricula and Primula Society held their fourteenth annual exhibition at the Edgbaston Botanical Gardens on the last day of April under favourable climatic conditions. The weather was genial and bright; everything possible was in favour of a good show. More plants were staged on this occasion than in any year since the society was founded. The attendance also was very satisfactory, and throughout the afternoon a goodly number of visitors were seen admiring the flowers.

Honorary exhibits were very fine, the groups being most artistically arranged. A charming group of perpetual carnations was exhibited by Messrs. A. R. Brown, Ltd., King's Norton. This firm also exhibited pot roses in fine condition, and were awarded the gold medal for the two groups. The Lapworth Nurseries Company, Hockley Heath, had a very fine exhibit of primulas and alpine plants, the primulas being the finest seen at the society's exhibitions. A silver-gilt medal was awarded the exhibitors. Mrs. Richard Peyton, Edgbaston, staged a very fine group of schizanthus, and was awarded a silver medal. Mr. H. N. Ellison, West Bromwich, was awarded a silver medal for a very fine group of ferns, which was tastefully arranged, and afforded much pleasure to fern lovers. The award of a silver medal was made to Mr. A. Edwards, Arnold, Notts, for rustic flower holders.

The Birmingham Botanical and Horticultural Society offered two medals to the exhibitors taking the largest number of points, and the large silver medal was won by Mr. Charles Winn with 131½ points, and Mr. W. M. Shipman won the bronze medal.

Mr. W. C. G. Ludford presented the two large silver medals to be awarded to the exhibitors taking the largest number of points with show and alpine auriculas, and both were won by Mr. Charles Winn.

Two large silver medals were presented by Mr. W. H. Parton, and that for the most points for show auriculas in the open classes was won by Mr. C. Winn, and that for most points in the open classes for alpine auriculas by Mr. W. M. Shipman.

SHOW AURICULAS.

The premier award in the class for eight show auriculas was won by Mr. W. M.

Shipman, of Altrincham, with Orpheus, Prince Charming, Geo. Lightbody, Shirley Hibberd, Molly Shipman, Peggy Gibson, and two seedlings. Mr. Charles Winn, of Selly Hill, Birmingham, was second with Henry Irving, Harrison Weir, Marmion, Mikado, Queen of Spain, Mrs. Henwood, Eucharis, and Geo. Lightbody; Mr. W. H. Parton, of Keighley, third. For six show auriculas Mr. Charles Winn was first, with Harrison Weir, Mrs. Henwood, Eucharis, Favourite, Henry Irving, and Olympus; Mr. W. M. Shipman second, and Mr. W. H. Parton third.

There was a brisk competition in the class for four show auriculas, and the premier award was made in favour of Mr. G. Savory, Birmingham, who had Acme, Marmion, Shirley Hibberd, and Abraham Barker. Mr. C. Turner, Handsworth, was second, and Mr. H. Saunders, Sparkhill, third. For two show auriculas Mr. J. F. Freeman, Sparkhill, was first; Mr. A. Wadley, Aston, second; and Mr. Geo. Barker, Sheffield, third.

There was a good competition in the class for single specimens, and the awards were made as follows: Green-edge—Mr. W. M. Shipman, first, with Shirley Hibberd; Mr. Charles Winn, second, with Mrs. Henwood; and Mr. W. H. Parton, third. Grey-edge—Mr. Charles Winn, first, with Marmion, and second with Olympus; and Mr. W. H. Parton, third. White-edge—Mr. Charles Winn, first, with Eucharis; Mr. H. J. Spencer, of Four Oaks, with Acme; and Mr. Geo. Barker, Sheffield, third. Self—Mr. C. S. Toogans, Hollywood, first, with Mrs. Phillips; Mr. A. Griffin, Saltley, second, with Mikado; and Mr. Charles Winn, with Queen of Spain. Yellow or buff self—Mr. Charles Winn, first and second, with Daffodil; and Mr. J. Freeman, Sparkhill, third, with the same variety.

The premier show auricula was George Lightbody, shown by Mr. C. Winn; and the premier seedling show auricula was Modesty, exhibited by Mr. W. M. Shipman.

ALPINE AURICULAS.

In competition for the prizes for eight alpine auriculas, Mr. W. M. Shipman won the premier award with a very fine set of plants, comprising Majestic, Roxborough, Charmer, Phyllis Douglas, R. C. Cartwright, Commander, and Sunrise. Mr. Charles Winn was a very close second with a very fine set of plants, his varieties being Roxborough, Majestic, Mrs. Danks, Phyllis Douglas, Prime Minister, Mrs. Douglas, Muriel, Mrs. Neville Chamberlain; and Mr. W. H. Parton third. For six, Mr. R. Holding, Bournville, was first with Argus, J. F. Kew, Unexpected, Majestic, Violet Vanbrugh, and Miss Baker; Mr. W. M. Shipman second, staging Unexpected, Phyllis Douglas, Majestic, and Commander, and Mrs. R. C. Cartwright; Mr. Charles Winn third. For four alpines, Mr. H. W. Miller, of Handsworth, was first; Mr. W. C. G. Ludford, Four Oaks, second; and Mr. J. D. Williams, Smethwick, third. For two alpines, the prize-takers were Mr. H. W. Miller, Handsworth; Mr. E. Saunders, Sparkhill; and Mr. H. J. Spencer, in the order of their names.

In competition for the prizes for single specimens with gold centre, Mr. C. Winn was first with Muriel; Mr. W. H. Parton second with Violet Vanbrugh; and Mr. H. W. Miller third, with Unexpected. In the corresponding class for varieties with light centre, Mr. J. Freeman, Mr. E. Saunders, and Mr. C. Winn were the prize-takers with Phyllis Douglas.

The premier alpine auricula was Majestic, shown by Mr. Charles Winn; and the premier seedling alpine auricula was Fred Freeman, from Mr. J. F. Freeman.

AWARDS.

First-class Certificate.—To alpine auricula Dorris Hill, from Mr. J. M. Eglington; to alpine auriculas Esther, Fred Freeman, and show self auricula Will Freeman, from Mr. J. Freeman; to Primula Lapworth Flesh, from the Lapworth Nurseries; to white edge show auricula Modesty, from Mr. W. M. Shipman.

Award of Merit.—Primula Lapworth Carmine, from the Lapworth Nurseries; Primula Lapworth Crimson, from the Lapworth Nurseries; Primula Lapworth Pink, from the Lapworth Nurseries; Primula Lapworth Salmon, from the Lapworth Nurseries; Primula Lapworth Scarlet, from the Lapworth Nurseries; Primula Lapworth Violet, from the Lapworth Nurseries; Primula Lapworth White, from the Lapworth Nurseries; Primula Lapworth Yellow, from the Lapworth Nurseries; Primula Lapworth Cardinal and Lissadell Hybrid, from the Lapworth Nurseries.

Highly Commended.—Alpine auricula Mrs. Saunders, from Mr. J. Freeman; and alpine auricula from Alpine Auricula Annie Crisp, from Mr. H. W. Miller.

Manchester Spring Show.

APRIL 29 and 30.

The Royal Botanical and Horticultural Society have revived their Spring Show, and held it in the Town Hall in conjunction with the National Auricula Society. The exhibits, which were non-competitive, were of a miscellaneous character, but orchids predominated. Mr. J. Howes, gardener to W. Thompson, Esq., Stone, had a grand bank of orchids, backed up with well-grown palms, ferns, etc. This exhibit occupied one end of the hall, and embraced odontoglossums, miltonias, cattleyas, cypripediums, etc. First-class certificates were awarded to Odontoglossum eximum Mrs. S. G. Guest, O. J. Howes, O. Charlesworthi, O. Teddie Thompson, and O. Walton Gem. A special gold medal was awarded to this fine exhibit. Mr. W. G. Garner, Altrincham, contributed a mixed display of roses, carnations, azaleas, with groups of primroses and polyanthus (Gold Medal). A. Warburton, Esq., Haslingden, set up a group of orchids, including good forms of cattleyas, odontoglossums, cypripediums, etc. (Gold Medal). Mr. A. J. Keeling, Bradford, sent a small collection of orchids, including good dendrobiums (Silver-gilt Medal). Mr. Q. J. A. Bruce, Chorlton-cum-Hardy contributed a miscellaneous group comprising good lily of the valley, liliums, palms, and foliage plants (Silver-gilt Medal). Mr. D. MacLeod, Chorlton-cum-Hardy, sent odontoglossums, cattleyas, miltonias, etc. (small Silver-gilt Medal).

Messrs. Muirhead and Willcock, Ashton-on-Mersey, put up two groups in which palms, bamboos, ferns were utilised as a background for rhododendrons, azaleas, liliums, roses, etc. (Silver-gilt Medal).

Mr. P. Weathers carried out the arrangements in his usual able manner.

ODONTOGLOSSUM PRINCESS MARY.

An attractive variety raised by Messrs. W. Bull and Sons. Flowers blush-white with red-brown blotches. See page 330.

THE ST. BRIGID ANEMONE.

No other anemone gives such brilliant shades as this, and as a showy spring-flowering plant it stands unequalled, for under ordinary circumstances it gives a wealth of blossom from early in the New Year until quite into the summer. Its usefulness for providing flowers for cutting over so long a period greatly enhances its value. The cultivation in a well-drained soil is very simple, but where a cold and wet soil has to be dealt with there is some little difficulty at times. In the former case tubers procured and planted early in the autumn in well-worked soil invariably thrive, while under the latter conditions they usually give unsatisfactory results; in fact, in my experience, it is waste of time to adopt it unless ample protection can be afforded to keep off excessive moisture and frosts. In such cases I strongly advise raising plants from seeds annually, and allowing the seedlings to grow undisturbed in the seed beds. So far I have not known this method to fail. Now is the most suitable time to take the matter in hand; choose a sunny position sheltered from north-east winds, in which to locate the beds; dig up the soil deeply, and mix with it leaf-mould and sand. Then form raised beds 5 feet wide by throwing out an alley 18 inches wide between each bed, and when these preparations are complete and the surface soil has been worked into a fine condition, draw out shallow drills 12 inches apart in which to sow the seed. It is difficult to sow evenly and thinly unless the seeds are mixed with some sharp grit or sand. During germination keep the seed bed moist, but after this has taken place little attention is required beyond keeping the beds free from weeds and moving the soil occasionally between the rows with a hoe. If a slight protection is given by fixing up a temporary framework on which a mat can be laid during cold weather, the early flowers will be saved from injury.

T. B. Field.

Wych Cross Place Gardens.

VEGETABLES FOR EXHIBITION AND HOME USE.

In dealing with a subject of this kind, there will no doubt be much difference of opinion as there are many points to be taken into consideration, such as the time of year crops are in use, and the relative value of each kind.

Potatoes.

Were I asked to name the most useful vegetable, I should, without the least hesitation, say the potato. This has for a long time taken the first place on a gentleman's table, and in many places is the chief food of the poor. Not only is it in use the whole year round, but it is served up in such a variety of ways that there would be much difficulty in finding a substitute. As a rule, however, tubers staged at shows would find but little favour with the chef. Take the early forced tubers as an example. As soon as these have attained the size of walnuts they are ready for use, and are much preferred to larger ones, as they are then served up whole. Were such tubers placed on the exhibition stand they would be passed over by the judges as being too small. When potatoes have attained their full growth those of medium size find most favour in the kitchen, whereas tubers for exhibition must be of large size, otherwise they would not be looked at, the awards going to some monstrosities that are of but little value except for cattle food.

Why is this? Exhibitions should be to encourage the production of such tubers that are the most useful, not the largest that can be grown. One is sometimes astonished at the enormous size cauliflowers and broccolis are exhibited. No ordinary cooking utensil would be capable of holding such overgrown specimens. Those that find most favour with the epicure are such that would go inside a small tea saucer—nice white compact heads, fringed with green leaves, that should please the most fastidious palate. Then again, are we not sacrificing the constitution of the plants to produce these monstrosities?

Brussels Sprouts.

Well might we ask where is that fine old variety of Brussels sprouts known by the name of "Imported"? This kind used to give us a supply of close, hard, compact sprouts right through the winter, no amount of frost seemed to take any effect either on the plants themselves or the sprouts they produced; while with many of the "improved" forms, as they are termed, the first frost in winter turns them black in the centre, rendering them quite useless for cooking. When walking round the vegetable stands at our shows one frequently hears the remark, What fine sprouts! More like small cabbages, and so forth. But those who see these fine sprouts after the first frost quickly alter their opinion. Brussels sprouts are exceedingly useful, and those of small, compact growth are by far the most serviceable, being better flavoured than the overgrown, coarse ones so frequently seen on the exhibition table. Yet judges will make their awards to these ill-conditioned exhibits, knowing full well that by doing so they are encouraging what is opposite to their convictions. Exhibitors grow these large specimens because they know that they will have no chance of obtaining awards unless they do so.

Carrots.

If you ask those who have had any experience in cooking, which they prefer, the nice, sweet, young, tender carrots that have been fresh drawn from the ground, or those fine roots that may have taken a silver cup or gold medal at a leading show, they would tell you the small, clean, fresh-drawn roots. Last autumn I saw staged, without doubt, one of the finest dishes of Doyenne du Comice pear that was ever exhibited. Yet these stood no chance with the judges against a dish of coarse Pitmaston Duchess, showing that judges as a rule go in for something big, regardless of quality. In dealing with vegetables, preference should be given to such productions that would give the greatest satisfaction when placed on the dining-table, not that which pleases the eye most in the exhibition tent. Were we judging plants, quality would certainly be taken into consideration, then why should not the same hold good with fruit and vegetables?

Asparagus.

Look at those giant heads of asparagus, about the thickness of a man's thumb, and as white as a piece of chalk, as tough as cow-hide, and no more fit for human food than so many blanched cabbage stalks. Yet such unnatural specimens are looked upon by some as being fine examples of their kind. Asparagus to be appetising ought to be nice and green for at least two-thirds of its length, not simply have green heads about the size of peas. There is no difficulty in growing these blanched walking-sticks, but they are not appreciated by the connoisseur. Why, then, is it that such productions are awarded the highest honours at our shows?

Onions.

Take, again, the onion. How many of those large specimens that grace the show tables during the early autumn are to be found in March? It is all very well to grow such, as showing what science and skill can do, but when it comes to a continuous supply something more is needed than exhibition specimens. One bulb to every eighteen inches or two feet of land is not the thing to be recommended for general use.

French and Runner Beans.

If you ask a chef which he prefers, those large pods of French beans and scarlet runners that are the pride of the exhibitor, or the small, tender samples, he would, without the least hesitation, say the latter. Large pods are nice to look at, but there is no more skill in growing them than in keeping up a constant supply of nice, useful sized ones.

Cucumbers.

I can well remember the time when cucumbers for exhibition were grown in glasses made specially for that purpose. When specimens from two or three feet long were no uncommon productions, glasses in like proportions were made for them to grow in; some were simply cylinders open at both ends, while others had only one end open. The pride with which the cultivator staged these monstrosities may be imagined, especially when he found they were an inch or two longer than his opponent's. It was then, So-and-so's black spine, or white spine, as the case might be. But such cucumbers are by no means the most serviceable, as they soon become bitter if not used. Small fruits, of from ten inches to a foot in length, are the best for general use, as a fresh one can be cut whenever required.

Leeks and Celery.

There has at times been much controversy about leeks. Some prefer the long, slender varieties, while others have a liking for the stout ones. As regards their cooking qualities, there is but little difference in them. Therefore, given weight for weight, the blanched portion of one is as good as that of the other. Leeks are by no means difficult to grow, provided one pays attention to their requirements; but to produce stems of first-class quality, liberal treatment must be accorded them. Celery is one of those vegetables that there can be no two opinions about, for the finest, best grown, crisp, blanched stems are the best, whether for exhibition, cooking, or for salads. They should not have a hard, knotty root, and the heart ought to be well extended up the plant. To produce the finest sticks the growth should be made evenly; for this reason it is not well to sow the seed too early in the season, and have the plants hanging about for a considerable time before they are planted.

H. C. P.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us of changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Road, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He would also be greatly obliged by correspondents sending early intimation of interesting local events related to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

DIMORPHOTHECA AURANTIACA.—E. O., Barham: Will you kindly tell me whether Dimorphotheca aurantiaca is a greenhouse plant or an outdoor annual? I had some seeds sent me, and I do not want to make a mistake with the plants.—Dimorphotheca aurantiaca is a half-hardy annual, it should be raised under glass, and at an early stage the seedlings should be planted singly in small pots. After due hardening off planting should take place at the end of May or early in June in a sunny border, or better still, on a sunny spot in the rock garden. This Namaqualand Daisy loves the sun. Of course, it could be grown in pots in a greenhouse, just as many other annuals are, we have seen it grown as a basket flower in a greenhouse with considerable success.

JABOROSA INTEGRIFOLIA.—F. E., Minehead: I shall be very glad if you will give me some information concerning a South American plant named Jaborosa integrifolia. Is it perennial, half-hardy, or hardy, and how can it be increased? I have one plant in a pot in a cold frame, and am at a loss to know the proper thing to do with it.—Jaborosa integrifolia is a native of Buenos Ayres, and is a perennial, hardy species belonging to the Order Solanaceæ. Rich sandy soil, and a sunny position on the rock garden or in a well-drained border, suits it, and if a rock or a shrub nearly shelters it from cold winds, so much the better. Increase is by division of the tufted growths during early spring; by cuttings of the unflowered growths during summer; or by seeds sown as soon as ripe or in early spring. Cuttings should be placed in a cold frame, and seedlings should have similar shelter. Jaborosa integrifolia has thick roots, leaves very like those of a dandelion, and white or yellowish bell-shaped flowers.

CARBON BISULPHIDE AND WOOLLY APHIS. — Messrs. Chivers and Sons, Ltd., Histon, Cambridge, write: "You were good enough in a recent issue to refer to our use of carbon bisulphide in fighting woolly aphis, popularly known as American Blight. As we have received a number of enquiries respecting this method, we think it should be mentioned that this substance is poisonous and inflammable, and must be used with great care. It should not be brought near a light, and anyone handling it should be careful not to smoke at the time." We have previously pointed out the danger that attends the careless handling of carbon bisulphide, and we are obliged to Messrs. Chivers for again referring to the matter. There is no danger at all in the use of the material if reasonable care is used by those who handle it.

DAHLIA IMPERIALIS.—M. R. B., Llangollen: I have been greatly interested in the excellent articles on dahlias and dahlia culture, which have appeared of late in THE GARDENERS' MAGAZINE, and I am wondering whether a collection of dahlia species would prove of interest in the garden. Can you tell me how many species there are, and where one could see them growing, and whether D. imperialis will flower in this country?—There are about half a dozen species of dahlia. Most of the species, or all of them, can be seen at the more important botanical gardens such as Kew, Cambridge, Dublin, etc.

THE FLOWER GARDEN.

A practical, up-to-date work on the Formation, Planting, and Management of the Flower Garden, and the Cultivation of Flowers and Plants adapted for outdoor culture. By T. W. SANDERS, F.L.S., Editor of "Amateur Gardening," etc.

CONTENTS.

FASHIONING THE GARDEN.—Aspect, Soil, and Methods of Levelling and Designing.

BEDS AND BORDERS.—How to Form and Plant Them to the best advantage.

WALKS AND PATHS.—Mode of Formation and General Management.

LAWNS AND TENNIS COURTS.—Formation from Seeds or Turves and Maintenance.

SHRUBBERIES. — How to Lay Out and Plant Effectively with Trees and Shrubs.

ROCKERIES AND FERNERIES.—Their Construction, Planting, and Management.

WATER GARDENS.—Arrangements, Selection, and Culture of Water-loving Plants.

ARBOURS, SUMMER-HOUSES, ARCHES, AND PERGOLAS.—Position, Style, Construction—Selections of Suitable Plants.

EDGINGS.—Turf—Tiles—Burrs—Box—Ivy, etc.

WILD GARDENS.—Their Arrangement and Suitable Plants and Flowers.

FENCES. — Brick Walls—Stone Walls—Wooden Fences—Privet—Holly—Box—"Quick-thorn" Hedges, etc., with approximate cost.

GARDEN PRACTICE.—Planting—Transplanting—Pruning—Watering—Mulching — Manuring—Weeding, etc.

PROPAGATION.—By Seeds — Cuttings—Layering—by Division—Budding—Grafting, etc., described and illustrated.

COLOUR ARRANGEMENT.—Schemes for Planting for Effect in Sunny and Shady Beds and Borders, with Plants and Lists of Suitable Plants and Flowers.

BEDDING.—How to Plant Beds Effectively so as to ensure a pretty garden during the year.

ANNUALS AND BIENNIALS.—All the best kinds described, with full cultural details.

BULBS.—The Best Bulbs and Tubers for Outdoor Culture, with modes of Cultivation.

PLANTS AND FLOWERS.—All the General Species and Varieties worthy of Cultivation, with the modes of Culture described.

CLIMBING PLANTS.—A Complete List of Evergreen, Deciduous, and Annual Climbers, and their adaptability for various positions.

TREES AND SHRUBS.—The most Suitable Kinds for Shrubberies, or as Specimens on Lawns—Culture—Management, etc.

PESTS AND DISEASES. — Insect, Animal, and Fungoid Pests, which are injurious to flower garden plants, fully described.

MESSENGER & Co LTD

HORTICULTURAL BUILDERS & HEATING ENGINEERS

LOUGHBOROUGH LEICESTERSHIRE

London Office: 122 VICTORIA ST S.W.

Such a collection would prove of great interest, and, so far as we are aware, there is no such collection in a private garden. D. imperialis is less hardy than the rest; it is a tall grower—8ft. to 12ft.—and produces its white, lilac-tinted flowers late in the season, hence it is necessary to place it in a warm, sunny greenhouse at the end of September to secure the blooms.

PALE YELLOW CALCEOLARIA.—S. E., Hornsea: Last year I saw a rather tall-growing calceolaria with pale-yellow flowers and soft green leaves used effectively in the public gardens at one of our Yorkshire seaside resorts. I intended to write you about it at the time, as I was much struck by its grace and beauty; unfortunately, it was not labelled. Possibly you could tell me what it was, and, if so, I shall be very grateful, because I propose to buy a few plants. It was not Calceolaria Burbidgei, which I grow and know quite well.—No doubt the plant you saw was Calceolaria amplexicaulis, which is a Peruvian species, 2ft. or so high, that carries clusters of soft lemon-yellow flowers. It is not hardy, but is easily propagated from cuttings placed in gentle heat in spring, or in a close frame in summer and early autumn. It is also easily raised from spring-sown seeds.

LARGE ANNUAL ASTERS.—H. G., Wittersham: Your article and illustrations dealing with large-flowered Annual Asters have interested me greatly. Can you inform me where I can obtain seeds of these American varieties to produce large blooms for marketing?—No doubt some of our leading English seedsmen would obtain the seeds for you, or you might write direct to Messrs. W. Atlee Burpee and Co., Philadelphia, U.S.A., an American firm of repute that advertises in our columns.

FOLIAGE PLANT FOR CUTTING.—M. M., Lichfield: I find some difficulty in obtaining very light and fern-like foliage during the summer-time for associating with cut flowers. My garden is of considerable size, and we have an abundance of flowers. As there is an invalid in the family, who can seldom get into the garden, we use flowers somewhat lavishly indoors. Will you add to the many kindnesses received through your columns by telling me the name of a hardy plant that will furnish elegant foliage for the purpose suggested?—Several of the thalictrums would prove very suitable for cutting, and if a batch of plants could be grown in a reserve spot, so much the better. T. minus is one of the very best for the purpose, as it has the grace of a maidenhair fern; T. rhynchocarpum and T. glaucum are also useful.

NAMES OF PLANTS.

G. S., Ryde.—Sparmannia africana.

W. R., Horsham.—Rubus spectabilis.

A. F. E., Chesham.—1, Camassia Cusicki; 2, Euphorbia palustris; 3, Choisya ternata.

M. L., Beckenham.—1, Pyrus acida; 2, Iberis sempervirens Garrexiana; 3, Uvularia grandiflora.

C. L. C., Matlock.—1, Daphne Cneorum; 2, Hippuris vulgaris; 3, Fritillaria persica; 4, F. meleagris; 5, Scilla hispanica.

CARNATION DUCHESS OF DEVONSHIRE.

I have been greatly interested in the discussion in THE GARDENERS' MAGAZINE with reference to the perpetual carnation Duchess of Devonshire. My experience, after cultivating this particular carnation for three years, prompts me to add a few words in its favour. From the time the cuttings are struck this variety invariably outgrows all others struck at the same time, and always produces a good strong healthy plant equal to the strongest-growing carnations I have ever seen, and gives us a splendid supply of blooms all the year round. My employer, R. Logan Kidston, Esq., will bear out my statement, that we are never without blooms of this carnation, beautiful in form and colour, and so useful, we are quite confident one of the freest bloomers in cultivation.

CATALOGUES RECEIVED.

PAUL AND SON, CHESHUNT.—A spring list of new and recently introduced roses; a capital and timely list for those who wish to plant roses from pots.

CHAS. P. KINNELL AND CO., LIM., 65, Southwark Street, S.E.—This firm's list is certainly one to keep on hand, as it includes pumps and hose, spraying machines, taps and syringes, all sorts of cutting and surface cultivation tools, ladders and barrows, ventilating gear, and lots of other things a gardener needs to know about.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, May 12.—Whit-Monday—Bank Holiday.

WEDNESDAY, May 14.—Royal Horticultural Society: Floral, Orchid, Fruit and Vegetable, and Narcissus and Tulip Committees meet at 12 noon. Lecture at 3 p.m on "The Coco-nut Palm," by Sir Everard Im Thurn, K.C.M.G.; Scientific Committee at 4 o'clock.

Tulip Show at the Royal Horticultural Hall.

THURSDAY, May 15.—Royal Gardeners' Orphan Fund Annual Festival Dinner at the Hotel Cecil, at 6.30 for 7 p.m.; chairman, the Right Hon. Col. Mark Lockwood, M.P.

The following dates of exhibitions have been recently announced:

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.

Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.

Ealing Horticultural Society, July 9.

Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.

Ulverston Rose and Sweet Pea Show, July 18.

Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.

Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.

Tunbridge Wells Flower Show, July 23 and 24.

St. Quintin Horticultural Society, July 24, in the Gun Club grounds Wood Lane, W.

City of London Rose Show, July 26, at Cannon Street Hotel.

Worth Horticultural Society, July 30.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Summer Effects in the Flower Garden.

In a consideration of the course of procedure whereby the most beautiful effects can be obtained in the flower garden during the summer season, there is not, at the present time, any occasion for touching otherwise than lightly on matters of a controversial character. No longer is it regarded as essential when approaching a question of this kind, that the time-honoured battle of Tender Bedders versus Hardy Flowers should be fought. At the present day all who are immediately concerned with the decorative aspects of outdoor gardening readily acknowledge that both tender and hardy plants possess much interest and beauty; and also that to maintain the attractions of the flower garden at a high level over the longest possible period a selection from the two classes must be made. The extent to which each section is drawn upon, and the manner in which the several kinds are utilised, will, as a matter of course, be determined by the taste of the owner of the garden and the conveniences for the preparation of the stocks of the several kinds. The characteristic features of the garden should also be taken into consideration; and, as a general proposition, it may be stated that in the preparation of colour schemes the suitability of the plants to the position they are to occupy should be carefully studied. It may also be suggested that in no garden will it be wise to fill the beds and borders with plants whose attractions fail in obtaining a full measure of appreciation. With the planting and care of hardy plant borders we are not now specially concerned, but to avoid misapprehension it may be pointed out that while they do not come within the scope of our reference to the production of summer effects in the flower garden, we regard a comprehensive selection of hardy flowers as essential to the full enjoyment of the flower garden, whatever may be its dimensions. Borders filled with the finest of the hardy perennials there should be, and, fortunately, there are comparatively few gardens in which such delightful features are not to be found. In addition to these there are usually geometric schemes or other groups of flower beds that occupy positions where they are constantly within view, and consequently should present a distinctly attractive appearance over the longest possible period. To ensure this continuity the utilisation of a considerable proportion of tender plants is a necessity, because of the relatively small number of hardy plants that bloom freely without a break from the opening days of summer until the season has well-nigh reached its

MR. FRANK CORDELL.

close. Beds occupying such positions as those here referred to may be maintained in a highly attractive state with but a short break from early in April until September is well advanced, by taking advantage of the aid the various bulbous and fibrous-rooted plants that bloom in spring are so well able to render. The use of two seasonal sets of plants will involve additional time and thought, but this will have ample compensation, inasmuch as by no other course of procedure can such attractive displays of flowers be produced for a similar period. Reverting to the preparation of the summer displays, in which plants that are not sufficiently hardy to withstand the conditions characteristic of the British winter will have a prominent place, it cannot be too clearly stated that the colour schemes for beds arranged in geometric or other groups may be readily adapted to the requirements of the most divergent tastes. As a general rule, schemes of colouring that are somewhat quiet in tone are most in accord with present-day ideas, and usually give the greatest degree of pleasure. They ought not to lack effective colouring, for the garden is no place for dulness, and bright effects without any semblance to the garish displays of colour that found so much favour during the greater part of the second half of the last century can be readily obtained. We suggest that, in carrying out schemes for beautifying the flower garden during the summer season, attractive flowers and handsome foliage should be utilised according to their relative values, and the taste of the owners of gardens. We appreciate to the full the improvement that has been made in summer bedding, to use a conventional term, within recent years, as the result of the endeavour to rid the flower garden of the appearance of flatness which was so characteristic a feature of the old style. There are several methods of planting by which the monotonous uniformity in the heights of the plants can be completely avoided. One is by the variation in the heights of the occupants of the different beds: another is by planting pyramidal or standard specimens some distance apart, and filling in the intervening spaces with dwarf plants of the same, or some other kind; and still another by furnishing the beds with the same kind, but using plants differing in height. The last method of planting can well claim to be the most recent, and, if not absolutely the best, it has so much merit that its steady increase in public favour may be regarded as highly satisfactory. Beds of zonal pelargoniums, heliotropiums, Calceolaria Burbidgei, and certain of the lantanas, of which the highly attractive variety grown so extensively in the London parks under the name of Delicatissima, is one of the best. For a very long period it has been the practice in the use of zonal pelargoniums to fill the beds exclusively with small plants raised from cuttings in the autumn previous, which bloom freely enough, but are so uniform in height as to become very monotonous long before the season has come to an end. A far more pleasing effect is produced by plants lifted from the beds in the previous autumn, and grown in five or

six-inch pots during the winter. Still better is the effect produced when a few bush-grown plants of larger size, and two or three low standards are associated with them. The older plants will bloom with greater freedom than will those some eight months old when bedded out; but what is of still greater importance, the effect is more pleasing. Very beautiful also are beds of heliotropiums formed with plants varying from about eight to thirty inches in height, and when arranged within a short distance of the house the fragrance of the flowers will be a constant source of gratification. In the case of the pelargoniums and heliotropiums, and also fuchsias, the beds can be filled with one variety, or with several varieties, provided the various shades of colour harmonise. The effect produced by setting specimen plants of heliotropiums, ivy-leaf pelargoniums, lantanas, fuchsias, Calceolaria Burbidgei, Swainsonia galegifolia alba, Streptosolen Jamesonia, in a low growth of other plants, is now so well known and generally appreciated that it need not be referred to except to suggest that the crowding of the specimens should be avoided. Boldness may also be given to the arrangements of summer flowers by the inclusion of a few beds of the free-flowering cannas of moderate height, which, in but few gardens, are grown so extensively as their merits would warrant. In addition to these, a bed here and there of such strong-growing ornamental-leaved plants as the ricinus, wigandia, and variegated maize will be useful for the diversity of form and colour they afford, but such beds must not be numerous or placed where their occupants will be liable to injury from strong winds. The mixed groups of tropical plants that are met with in some of the public parks are not well suited for private gardens, but any well-grown agaves, cordylines, dracænas, palms, and yuccas that may be available should be taken advantage of, and arranged singly in suitable positions. Indiscriminate mixtures of flowering plants are equally undesirable, but, happily, they are now so seldom seen in gardens that there is no occasion to do more than make this passing reference to them.

Mr. Frank Cordell has two claims upon our attention. He is head gardener to Alfred Blades, Esq., Rockfields, Reigate, and in that connection has proved himself a particularly successful cultivator of chrysanthemums, roses, and sweet peas. He is also secretary of the Reigate and District Chrysanthemum Society, an office he has held since 1910, but for four years previously he was joint secretary with Mr. W. C. Knight. Mr. Cordell worked for some time under his father, who has been head gardener at Hubbards Hall, Harlow, for forty years. On leaving home he went to Messrs. H. Cannell and Sons, Swanley, working there in the various departments, and visiting the surrounding market gardens and fruit farms during his spare time. From Swanley he moved to Elmhurst, Bickley, where Mr. C. Payne was then a most notable and successful exhibitor of chrysanthemums and pot plants. Here Mr. Cordell stayed six years, and he speaks very highly of the advice and assistance received from Mr. C. Payne during that period. At Rockfields Mr. Cordell has keenly interested and appreciative employers, both Mr. and Mrs. Alfred Blades finding a vast amount of pleasure in their pretty garden. They both render great help in connection with local horticultural functions, and their love for flowers and plants leads them to extend that encouragement which so greatly helps a gardener to success at home and in the exhibition tent.

Chelsea Flower Show. — The great spring exhibition, which will be held by the Royal Horticultural Society in the grounds of the Royal Hospital, Chelsea, on Tuesday next and the two following days, has the promise of proving a great success. The change from the somewhat limited area of the gardens of the Inner Temple to the spacious grounds of the Royal Hospital has rendered it possible to effect immense improvements in the arrangements, and to greatly increase the facilities given to exhibitors for the display of the products of their skill. This year's exhibition is planned on the lines of the Royal International Horticultural Exhibition that was held at Chelsea last year; it will of necessity differ from that gathering in some of its features, but it will evince an immense advance on previous spring shows held by the Society. The exhibits will be arranged in a huge tent of a similar character to that which formed so striking a feature at Chelsea last year, and they will occupy at least three times the area devoted to them at the Temple shows, and yet leave ample space for visitors to move about in comfort. The great features of the exhibition will be the orchids, roses, rock and water gardens, tulips, hardy herbaceous and alpine flowers, fruits, and vegetables, ornamental evergreen and flowering trees and shrubs, pergolas, and horticultural sundries. The rock and water gardens and the pergolas will be in the open. In our next issue we shall give a full and illustrated report of this great demonstration of British horticulture.

Tulips in the Preston Parks.—The displays of early-flowering tulips in the Preston parks have been especially fine this season, and the brilliant colour effects have afforded immense pleasure to the visitors. The most noteworthy of the displays were those in Miller Park, and particularly attractive were the beds of White Falcon and Crimson King, Princess Marian and Prince of Austria, Proserpine, Keizerskroon, Joost van Vondel, and Yellow Prince, alongside the Derby Walk. These, with other varieties, were employed with good effect in the beds surrounding the sundial, one of the more noteworthy objects in the park, and in those contiguous to the West Cliff entrance. The Parks Superintendent, Mr. F. Tye, may be heartily congratulated on the success he achieved.

A Sunless Whitsuntide.—The Whitsuntide holidays have not been a success from the point of view of those who love to spend the brief respite from duty largely in the open air. The Saturday afternoon was only moderately fine in the Metropolitan area, and Sunday consisted of very heavy showers of rain and hail, punctuated by brief bursts of sunshine. The Bank Holiday was still worse, and, with only six minutes of sunshine recorded, it may be regarded as sunless for all practical purposes. But though the day was unpleasant only one-twenty-fifth of an inch of rain fell during the twenty-four hours, and most of this came late in the afternoon. Kew Gardens did not receive its full share of visitors, and those who came "down to Kew in lilac time," and to see the bluebells and the tulips, numbered about 86,000, or about half as many as on the fine Whit Monday of 1912. The Natural History Museum, British Museum, and Victoria and Albert Museum were well patronised, the visitors being 8,057, 6,832, and 8,633 respectively. Nearly 50,000 people were conveyed by rail to the Epping Forest stations, and probably almost as many more went by omnibus, cycle, motor, or on foot. Hampstead Heath was comparatively deserted, but the Cart Horse Parade at Regent's Park was well attended, and some 30,000 people went to Hendon to watch the flying machines and airmen. Hampton Court attracted about 120,000 people, but there was great disappointment that, while the gardens were open, the Palace itself was shut. The Zoological Gardens had a busy time, as 49,410 people passed through the turnstiles, or ten thousand more than on the corresponding holiday of 1912. In spite of the drizzle many thousands went for country rambles in the home counties, while crowds started early for the seaside, and the Continental traffic was unusually heavy.

Flowering of Catalpa and Tulip Trees.—A correspondent of "The Globe" contributes the following note to the issue of that journal for the 3rd inst. "The catalpa tree, which is rarely to be seen in this country, except in ornamental grounds and gardens, is in fine blossom just now. Occasionally it graces a suburban lawn, and never fails to excite wonder and admiration, with its profusion of handsome blooms of white and pink, and streaks of lake. Its branch tracery is very fine, and its boughs numerous, although the tree does not grow very high. It takes its name probably from the Catawba River, but there are other varieties than the American, the Japanese being very beautiful. The almond tree blossomed so early this year that the catalpa bloom has come very opportunely to fill the interval between the flowering lilacs, laburnums, hawthorns, etc." It need hardly be said that the tree to which the writer refers is not a catalpa, as all the species belonging to the genus are summer-flowering. The well-known American species, C. bignonioides and C. speciosa, bloom in July and June respectively, and the Chinese and Japanese species, C. Bungei and C. Kæmpferi, also bloom in these months. We have during the past six or seven weeks also seen letters in the general press referring to the flowering of the tulip tree, with its rose-pink flowers. The specimens to which the writers refer are not catalpa or tulip trees, but are examples of the well-known Magnolia Soulangeana.

Azalea Day in Vienna.—According to the correspondent of the "Daily Telegraph," azaleas, red and rose, were the charity flowers of Vienna this season, and with the last day of the fête came the first awakening of spring weather. People were readier to buy than ever, for they realised better what the selling of individual blossoms meant. From seven o'clock in the morning every workman or workgirl went to business wearing an azalea, and by midday no one might appear on the street without the token of charity. Officials, policemen, taxi-drivers, motor omnibus men, each wore the decoration of the day. Prices were not quite so high as those of last year, half a guinea a bloom having been reckoned as the biggest sum paid. Over sixty sacks of azalea flowers were distributed, and the reckoning of the money obtained for charity is put at 200,000 crowns, as against 250,000 last year.

Combating Enemies of the Oak.—For some years past the younger oak trees in the plantations within the boundaries of Richmond Park have been seriously injured by the ravages of the caterpillars of several moths that have a liking for the oak. More especially have the four hundred trees suffered in the Ham Cross Plantation, which was formed nearly one hundred years since. The principal damage has been done by the larvæ of Tortrix viridana, T. quercana, and Dasychira pudibunda, many of the trees having of late made but little progress

owing to their defoliation, and, in numerous instances, the trees have lost their tops. With a view to stay the plague of caterpillars, and prevent, as far as possible, further damage, Professor Lefroy, of the Royal College of Science, South Kensington, advised the treatment of the trees with a spray solution. The advice was acted upon, and as this involved spraying operations on a more extended scale than had previously been attempted in this country, he arranged to carry them out himself, with the aid of the students of entomology at the Royal College of Science. The spray used was lead chromate in solution, and it was applied with the aid of a powerful petrol-driven machine, which has been designed by Messrs. Merryweather for use in the Tropics, more especially for spraying extensive rubber plantations. The spraying of the trees in the plantation mentioned occupied two days.

"Botanical Magazine."—The new plants illustrated in the current issue of this publication comprise Rhododendron Wrighti, a handsome Himalayan species, bearing large trusses of straw-coloured campanulate flowers; Deutzia longifolia, a beautiful Chinese species, with rose-coloured flowers, which has become generally known as D. Veitchi, the identity of the plant with the form described by Franchet as D. longiflorum not being known when its now familiar name was given it; Strongylodon pseudo lucidus, an attractive stove climber, with clusters of orange-red flowers; Dendrobium Schuetzei, a handsome species, introduced from the Philippines, and bearing large pure white flowers, that somewhat resemble those of D. Dearei; and Saxifraga Stribznyi, an interesting and attractive species, found on Mount Rhodope, with clustered rosettes and bright red flowers, which, in favourable weather, make their appearance as early as February. Cut specimens of the flowers of Rhododendron Wrighti were submitted to the R.H.S. Floral Committee, when an Award of Merit was made in its favour.

Perpetual-flowering Carnation Society.—We are pleased to learn from Mr. T. A. Weston, the hon. secretary, that the progressive policy of this society continues eminently successful. The new departure of holding a provincial show has been amply justified by the results, the exhibition at Leamington having strengthened the membership without cost to the society. Since November 1 last 102 new members have been elected, the total now being 469. The committee have arranged a dinner and entertainment for members and their friends on Wednesday, the 21st inst., at the Holborn Restaurant. We have no information as to the time fixed for the dinner, but we believe it will be about 7 p.m.

Possible Purchase of Box Hill.—It is reported that the question of the possibility of formulating a scheme for the purchase of Box Hill, Dorking, is receiving the consideration of the National Trust, and that if satisfactory terms can be arranged an appeal may be made to the public for funds. With reference to this report, "The Times" observes that negotiations between the National Trust and the owners of the estate would hardly fail to result in placing before the public a feasible scheme by which this most beautiful hill and its superb outlook might, at a moderate cost, be secured as the inalienable heritage of the nation.

ACANTHACEOUS PLANTS FOR AUTUMN AND WINTER FLOWERING.

The order Acanthaceæ is an extensive one, and of the various plants composing it a great many are justly valued for their ornamental qualities as flowering subjects. They are, for the most part, of easy culture, and, with reasonable care and attention, will bloom profusely. In many of them, too, the flowering period is not limited to any particular season of the year, so that a good display of blossoms may be had at any time, while others bloom naturally during the autumn and winter months. Such a one is Jacobinia chrysostephana, which has crowns of orange-coloured flowers that form such an attractive feature during the dull weather we often experience in the declining days of the year.

Most of the acanthads are of a half-shrubby character, and many of them are of an upright habit of growth, so that it is useless to pinch them in order to obtain bushy plants, as a bold flower head is more effective than several small ones from minor shoots.

As a rule, the temperature of an intermediate house suits them best, because, except in summer, they need a structure warmer than an ordinary greenhouse, and in the heat of the stove they are apt to run up weakly. Of those that may be had in flower in autumn and winter there are aphelandras of sorts, among the best being A. aurantiaca, orange-scarlet; A. chamissoniana, yellow; A. Fascinator, scarlet; A. nitens, scarlet; and A. tetragona, bright scarlet. Barleria strigosa has flower heads disposed much as the aphelandras, but the blossoms themselves are

A BOLD ARRANGEMENT OF CALCEOLARIA BURBIDGEI,
With a groundwork of violas, nemesias, etc., at Kew.

comparatively large, and of a pleasing shade of light blue.

Crossandra undulifolia, which not long since was given an Award of Merit by the Royal Horticultural Society, has very pretty orange-salmon flowers. Though it usually flowers in the spring, blossoms may be had in the autumn. Dædalacanthus nervosus is our old friend Eranthemum nervosum, which is a general favourite, as it produces its beautiful metallic blue flowers in the depth of winter. An allied kind, Dædalacanthus Watti, also known as D. parvus, flowers in the autumn. It is a plant of shorter growth, with deep bluish-purple flowers.

The genus Eranthemum is an extensive one, and while the flowers are borne in terminal spikes or heads, as in most acanthads, in a few they are scattered along the shoots. Among the best are E. Andersoni, white, spotted red; E. albiflorum, pure white, like single lilac; E. gracilliflorum, lavender; E. seticalyx, reddish-yellow; and E. tuberculatum, pure white.

As a class the jacobinias are among the most popular of the acanthads, and several of them are extensively grown in gardens. All of them may be had in bloom in winter. A selection of the best would include J. chrysostephana, above alluded to; J. coccinea, scarlet; J. Ghiesbreghtiana (syn. Sericographis Ghiesbreghtiana), scarlet; J. magnifica, whose varieties vary from rose to deep reddish-rose; J. pauciflora (syn. Libonia floribunda), red and yellow, a well-known plant; and J. penrhosiensis, crimson and gold. Peristrophe speciosa is a well-known weed in the Tropics, and much grown here for winter blooming, the magenta-coloured flowers being borne in great profusion.

The ruellias are a numerous class, and some of them are very showy, especially R. acutangula, scarlet; R. amœna, crimson; R. macrantha, much grown in many gardens, and, I believe, one of the largest-flowered of acanthads, flowers purplish-rose, with dark veins; and R. rosea, with blossoms of a pleasing shade of bright rose. Schaueria calycotricha (Justicia calycotricha) has curious fluffy heads of yellow flowers, and is well worth growing for the sake of variety as well as for its free-flowering qualities. Generally at its best early in the new year.

Owing to the fact that many of them are of a climbing nature, the different thunbergias stand out distinct from most acanthaceous plants. The large-growing T. grandiflora, with light blue flowers, and the pure white T. fragrans will often bloom well on into the autumn, but, as a rule, most of the others flower at different seasons of the year. The last acanthad to mention is one of the most popular, namely, Thyrsacanthus rutilans, usually in better condition before Christmas than after. It is a plant of tall growth, with long pendulous racemes of bright crimson-coloured tubular-shaped flowers. W. T.

Ceanothuses under Glass.—The numbers of hardy trees and shrubs that are forced prematurely into bloom for decorative purposes in the spring are greatly on the increase. The ceanothuses are, however, but little considered in this way, though they form a very pleasing variety to the whites and yellows which, as a rule, predominate in the early groups of forced shrubs. For flowering under glass only, those kinds that bloom early in the year should be chosen, as the members of the summer-flowering race are quite unfitted for the purpose. Among the most desirable species are C. dentatus, C. rigidus, and C. Veitchianus. In all of these the leaves are small, dark green, and the flowers of some shade of blue. —W.

SOME BEAUTIFUL TENDER BULBOUS PLANTS.

Over the greater portion of the British Isles the subjects of this note can only be grown under glass protection, but are well worthy of being employed for conservatory decoration, owing to their beauty when in flower. In warm, wall-backed borders in the south-west, however, all can be successfully cultivated in the open air and all have flowered here.

Bessera elegans.

This is a native of Mexico, bearing on slender stems, 18in. to 2ft. in height, from six to twelve drooping, scarlet flowers, about 1½in. across. The leaves are very narrow, and about the same length as the flower-stalks. The stamens are violet-purple with green tips. There is a variety having the inner surface of the petals white with a margin and central band of scarlet. Both forms have appeared here.

Cypella Herberti.

A native of Buenos Ayres, bearing tigridia-like flowers of apricot-yellow colour, 3in. in diameter, on stems about 18in. in height. The blossoms are very pretty, and have a black line down the centre of each of the three petals. Several flowers following one another are often produced on the same stem.

Cypella plumbea.

This is a native of Mexico, and is a far stronger grower, reaching a height of from 3ft. to 4ft. Its flowers are 4in. across, and are generally of a dull lilac-blue, though there is a form in which the blossoms are of a brighter colour.

Milla biflora.

This is a native of Mexico, bearing generally two, but sometimes three, sweetly-perfumed flowers of dazzling whiteness about 3in. across. The reverse of the petals is lined with green. The foliage is rush-like, and the flower stems average 1ft. in height. A group of plants in full bloom is an exquisite sight.

Nerine Fothergilli major.

The Guernsey lilies are from the Cape of Good Hope, and this is the handsomest variety. The large flower-heads, composed of twenty or more individual blossoms, about 3in. in diameter, are of bright scarlet, the petals in the sunshine having the appearance of being powdered with gold dust. The flower-stems are over 20in. in height, and the strap-shaped leaves attain a length of about 9in. by the time the flower-truss is at its best.

Nerine Bowdeni.

This is of recent introduction, and its flowers are considerably larger than those of any other species. The blossoms are pale rose in colour, with a central line of deeper hue. It flowers freely in the open air here.

Zephyranthes candida.

This is a native of Peru, and bears pure white flowers about the size of a crocus on stems about 9in. in height. It flowers in the autumn, and is a good companion to the belladonna lilies.

Zephyranthes atamasco.

This is said to be a native of Carolina and Florida, but, in spite of its more northern habitat, it has proved harder to establish in the open than Z. candida. However, here both are doing excellently and flower profusely. It is a white-flowered species, bearing blossoms from 3in. to 4in. in diameter, and is generally stronger in growth than Z. candida. Both have evergreen foliage. Two other zephyranthes grown here are Z. Andersoni and Z. grandiflora, but neither have as yet flowered.

Wyndham Fitzherbert.

Kingswear, S. Devon.

ANCHUSA ITALICA, DROPMORE VARIETY.

This is one of the best, if not the best, of the hardy plants of recent introduction. It has attained a wide vogue in a short time, and bids fair to become almost universal in gardens of any size before long, though its uncertain perennial character in many soils tell against it with *laissez faire* gardeners. In wet soils it will rarely flower a second year, while in light soils it is a true perennial, though not a long-lived one, and in some, especially if they are rich in lime (the Borage family generally are partial to chalk) it sows itself freely, and comes to be regarded almost as a weed.

Where there is a difficulty in keeping it, and this seems to be the more general experience, we are recommended to propagate it in late summer by cutting up the roots after the manner of sea-kale; that is, cutting up the thick fleshy root—about the size of a large office ruler—into pieces two or three inches long, and planting them in a reserve piece of ground. The amateur does not always succeed with this, and if the soil is a wet one, more generally fails. The latter has been my experience, and I adopt the plan of raising seedlings every spring, as with some other doubtful perennials. The seedlings vary a good deal, but they are nearly all good, the differences being mainly in the colour and size of the flowers.

The important thing is to raise the seedlings as early in the year as possible, so that large plants may be obtained. The best way of all, perhaps, is to sow the seeds in groups of half a dozen where the plants are wanted to flower, and then pull out all the resulting seedlings but one, and that the strongest. Positions are not always ready for them in February or March, or the ground is not in good order for sowing. In such circumstances seeds may be sown in pots in February, say, half a dozen in a five or six-inch pot, and the latter set in a frame; if warm, all the better. The seedlings will remain in the seed-leaf, or incipient third-leaf, stage for weeks, and appear to be doing no good, but, on turning out the pot, it will be seen that they have not been idle. I have measured the roots of seedlings scarcely more than just showing the third leaf, and found the longest roots seventeen or eighteen inches in length.

In planting out, the holes should be made deep enough for the roots to go straight down their full length, a crowbar being used for the purpose, or a small hole dug and a dibber used at the bottom of it. If the ground is in fairly good heart, the plants should be making leaves a foot and a-half in length by August, and the following spring or early summer each plant should make a bush three feet in height and as much through. Alger Petts.

Strobilanthes Dyerianus.—This warm-house acanthaceous plant is generally grown for the sake of its handsome leaves, which, especially when young, are delightfully shaded with pink, while there is in addition, a violet metallic lustre. The flowers, however, are well worth consideration, being, as in most of its relatives, borne in a terminal spike. They are lilac, marked with purple.—K.

MALMAISON CARNATIONS.

Malmaison carnations are not grown so extensively as they were previous to the introduction of the many fine forms of the perpetual carnation now in cultivation, owing undoubtedly to their flowering season being limited to a few months during the spring and early summer. Nevertheless, their rich, clove-scented flowers, whenever obtainable, are as highly esteemed as ever, and well grown plants, carrying from 50 to 70 blooms, cannot be surpassed for a gorgeous display by any other type of carnation.

When the layers have been down from four to six weeks they will be sufficiently rooted to support themselves, and should be severed entirely from the old plant. In a few days they will be ready for potting, and a 3in. pot will be found the most suitable and convenient one to use at this stage, and, except in the case of early layers, I prefer to winter them in this size, potting them into their flowering pots the first week in February. To my mind, this practice commends itself in two ways: first, the room required by the plants through a season when all space under glass is valuable, is much less than if they had been potted into 6in. pots in the autumn, and the possibility of over-watering is greatly reduced just at a period when that operation is most critical.

Some growers chiefly rely on their layers for producing the bulk of the flowers they require, only potting on a small percentage for flowering the second year. The condition of the plants at the end of their first flowering season usually determines this practice, for unless one has well-grown plants free from rust, etc., it would not be economical or wise to pot them into larger pots, but when one has plants in their second year carrying from 20 to 24 blooms in a 9in. pot, it is then that one has the best return for space. Such plants potted into 14in. pots and grown yet another season will, with care, make huge specimens, carrying from 50 to 80 blooms. The dwarfer-growing varieties lend themselves best to this treatment, as they do not require so much head-room or attention to staking.

If it is possible to arrange it so, Malmaisons should have a house devoted entirely to them, and the most suitable structure is one which has a span roof, and is provided with running ventilators top and bottom on both sides, with sufficient hot-water pipes to exclude frost. Such conditions greatly facilitate management, as the plants revel in a buoyant, dry, cool atmosphere, and this can only be maintained by giving plenty of ventilation whenever the outside conditions will permit, without allowing the temperature to fall much below 40 degrees. In bright weather shading becomes necessary, and a thin canvas blind is much to be preferred to a coating of permanent shading. Artificial heat must be only used to exclude frost or to dry the atmosphere of the house. On very dull, damp days, through the winter, when heat is being used for the latter purpose, as much ventilation as practicable should be kept on the house.

HOUSE OF MALMAISON CARNATIONS (PRINCESS OF WALES) AT MULLABODEN, KILDARE, IRELAND.

To grow Malmaisons successfully close attention to cultural details must be exercised at all times, as any neglect in ventilating, watering, and in using artificial heat, will soon have a marked effect and end disastrously.

Propagation is usually effected by layering; this operation is performed as soon as the plants have passed out of flower by removing them to a cold frame containing a sufficient depth of light, sandy soil in which to plunge the pots to the rims. The young growths are then brought down and layered, the soil being kept moist and the frame well ventilated and shaded through the hottest part of the day. In a fortnight's time the lights can be entirely removed, allowing the layers to have full advantage of the light and sun; this lays a foundation of sturdy short-jointed growth, a most important condition if good specimen plants are desired at a future date.

Watering the plants calls for minute attention, especially so through the winter months; at this period withhold water from a plant entirely until its pot clearly rings when tapped. Once growth becomes active and the pots are getting filled with roots, they will require a considerable amount of water, and at such a stage stimulants in the form of blood manure, or a prepared carnation manure will be found beneficial if applied frequently and with care; soot-water can be used at any period; in fact, I advocate a canvas bag containing soot being constantly immersed in the tank of water within the Malmaison house.

EVERGREEN RHODODENDRONS.

The genus rhododendron is one of the grandest in all the range of horticulture, and is of more than ordinary interest to gardeners of every degree, as its members figure prominently in all good gardening, both under glass and in the open air. The genus is an extensive one, and, although gardeners differentiate between rhododendron and azalea, the latter is incorporated by botanists under the former; hence the genus comprises both evergreen and deciduous shrubs. Of the former, Europe, North America, China, and Japan, the Sikkim Himalaya, and mountainous districts of Malay furnish by far the great majority of species known to gardens. The species common to the Malay are not hardy out of doors, but require the temperature of a warm greenhouse to unfold their richly coloured flowers. The Himalayan kinds occupy the border line; that is to say, in the south and south-west generally, and along the west coast of these islands, their cultivation may be attempted with greater or less success. Some gardens, indeed, contain examples of Himalayan species that outclass every other form of arborescent growth capable of enduring open-air conditions in this country, and that in some notable instances even rival those in their native forests. It is this group whose influence is indelibly written upon the hardy hybrid rhododendrons, as we know them today, of which the popular Pink Pearl is a familiar instance It is notorious, however, that these hybrids are the progeny of comparatively few species, and then not direct, but second and even third crosses have been effected in their production.

The species most directly interested are R. ponticum, R. caucasicum, R. catawbiense and R. maximum, with R. arboreum and R. Griffithianum from the Himalaya; to the latter we ascribe the rich colours and the large expanded bells of the hybrids, together with their early-flowering propensities. The influence of the North American and European species is towards hardiness and late flowering, the latter attribute being most clearly traced to R. maximum. In their native haunts, rhododendrons experience pure air and a humid atmosphere, with abundant sunlight. The soil is generally a rich vegetable earth that is always cool and moist, and in which water never stagnates. Like all the ericacæa, they strongly object to lime in the soil. When first grown in the open in this country peat was insisted upon as the staple constituent of the soil, but this position has been abandoned, as experience dictates that equally good, and in some cases better, results are obtained without it; a light to medium loam is probably the best medium in which to plant, as if this is enriched with old, decayed manure and leaves, it forms a compost into which the plants root eagerly. Clay soils are most difficult to bring into condition, but, provided these are well drained to start with, and shallow planting practised, forcing up the ground level with decayed leaves, loam, and manure, good results generally follow, as splendid examples occur in many Surrey gardens grown under these conditions.

RHODODENDRON LODER'S WHITE,
At South Lodge, Horsham, the residence of F. Du Cane Godman, Esq.

Rhododendrons are particularly sensitive to the virtues of rotted farmyard manure, and if ever the foliage becomes thin or pale-coloured, as occasionally happens, nothing brings them quicker into condition again than thoroughly saturating the soil with liquid manure made of this material, and applied as the young growths are developing. Where the conditions as to soil and moisture can be provided, rhododendrons succeed in full sun; they are better, however, with some light shade, which applies most particularly to the evergreen kinds, while the Himalayan group require in addition abundant shelter.

Himalayan rhododendrons have merit apart from the flowers, for the foliage is interesting at all seasons, and exhibit great variety in form and colour. The flowers are generally of a large size; in some the colours are exceedingly delicate, in others richness and brilliancy combine, and result in flowers of great splendour. In R. grande and R. Griffithianum the buds are pearly-pink, opening to snowy-white; in R. Falconeri the flowers are creamy-white; pure yellow is found in R. campylocarpum; dull crimson in R. cinnabarinum; rich red in R. arboreum, and glowing blood crimson in the flowers of R. Thomsoni. The hybrids of Himalayan rhododendrons are exceedingly numerous, R. Griffithianum having been extensively employed as a parent; R. ponticum × R. Griffithianum gave Alice Mangles, with pale lilac flowers; the latter crossed with R. album elegans gave R. Manglesi, ivory-white, with crimson spots; White Pearl, Loder's White, and Gauntletti are forms of the latter. R. Griffithianum × R. Hookeri gave R. Kewense, flowers rosy-pink, much paler with age, the first-named species crossed with R. Thomsoni resulted in Beauty of Tremough, Glory of Neujerrick, and Gill's Triumph, raised by Mr. R. Gill at Tremough, near Falmouth. R. Griffithianum × R. Fortunei gave R. Loderi in the gardens at Leonardslee, where these magnificent subjects are extensively grown, and where numerous hybrids of great promise are on trial. R. Fortunei × R. Thomsoni gave R. Luscombei; R. Fortunei crossed with garden hybrids by Messrs. Paul and Son gave a number of beautiful sorts, of which Duke of York, Duchess of York, Mrs. Thiselton Dyer, and Profusion have received the award of the R.H.S.

The hardy hybrid rhododendrons that have the greatest utility in garden decoration, and that combine beauty of the highest order, are not the direct offspring of tender species, but usually hybrids of the second or third generation crossed with a hardy species. They are characterised by having compact, yet full, flower-heads; individual flowers of good substance and large size; colours showy and clearly defined, and flowering under ordinary conditions in June. So numerous are the varieties in this section that only a small proportion can be mentioned.

White.—Baroness H. Schroder, white, spotted maroon; George Hardy, white, of immense size; Mdme. Miolan Carvalho, blush to white, green spots; Mrs. John Clutton, clear white, yellow spots; Mrs. Tom Agnew, pure white, lemon-yellow blotch; The Queen, pink to white.

Rose and Pink—Concessum, rose, with lighter centre; Gomer Waterer, white, shaded blush, enormous trusses; Mrs. William Agnew, pale rose, yellow centre; William Davies, deep pink, small dark spots; Strategist, clear pink, large trusses; Charles Kingsley, bright rose; Pink Pearl, flesh-pink, trusses of the largest size; Lady Eleanor Cathcart, bright rose, chocolate spots; Mrs. R. S. Holford, salmon-rose; and W. E. Gladstone, deep rose.

Red.—Doncaster, intense scarlet; Frederick Waterer, fiery crimson; Ascot Brilliant, deep blood-red; Caractacus, purplish-crimson; John Waterer, glowing carmine; John Walter, crimson; and Michael Waterer, bright scarlet crimson.

Lilac and Purple.—Everestianum, rosy-lilac; Baron Schröder, plum colour, yellow centre; and Joseph Whitworth, dark purple-lake, dark spots.

Heavy Blotched or Bi-coloured.—James Mason, light centre, scarlet margin; Helen Waterer, white, bright crimson edge; Lady Clementina Walsh, light blush, edged pink; Duchess of Sutherland, blush white, margin rosy-crimson; Mrs. John Penn, salmon-pink, bright lake edge; Mrs. Tritton, rosy-crimson, white centre, brown blotch; and Mrs. Isaac Davies, delicate blush, heavily blotched maroon.

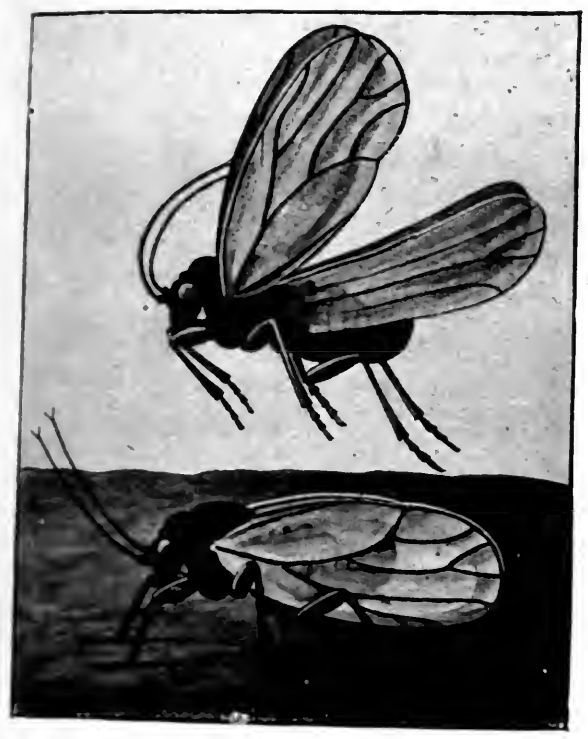
Coombe Court Gardens.

SUMMER PESTS IN THE GARDEN.

INSECT ENEMIES OF FRUIT TREES.

It is in Maytime, when country folk begin to talk freely of "blight," and the old opinions, which have not yet been argued



APPLE SUCKER (PSYLLA MALI).
Insects at rest and in flight, much enlarged.

away entirely, are expressed by local wiseacres that the insect pests, which are all included under the heading of "blight," come this month on dull, gloomy days, and are borne on the wings of the wind after the manner of the plague of locusts in ancient Egypt. Science in recent years has thrown a good deal of light on the habits and histories of the insect pests which worry fruit growers and gardeners, but there is a good deal yet to be learnt about methods of eradication where some of them are concerned. There are two ways, however, of dealing with insect foes: one is to prevent and the other is to destroy. The former has for its object the prevention of eggs hatching into life, but the season for that has now gone past, for simultaneously with the growth of young vegetation comes the feeding time of insect foes, and while this period lasts it is the business of the grower to fight for his crops and deal death to the hordes of living insects that seek to damage them in one way or another. Legion is the name of the insects which seek to satisfy their ravenous appetites at this time of the year; some are not particular, but feed in a general way, others have their own special food plant, and attack no other, and, while some are capable of doing widespread damage, we should not know much of others if they were not set out in the formidable lists arranged by entomologists. For the purpose of this article we can afford to overlook the uncommon pests, and deal only with those that are to be found in practically every orchard and garden at this time of the year, beginning with the enemies of fruit crops.

Apple Pests.

We may divide the foes that wage war on the apple crop into two sections mainly, i.e., the sucking insects of the aphis type, and the caterpillars, which actually feed on the fruit and eat the foliage, thus spoiling crops, and crippling the trees.

Apple Sucker (Psylla Mali).—This is undoubtedly one of the worst pests of the apple crop, and the presence of the small aphis-like creatures is always indicated by the crystal globules of honeydew matter in the flower truss. When the apple suckers have done their evil work of extracting the juices from the flower stems the trusses of blossom turn brown, and they remain in this state for some time on the trees. It was for the purpose of preventing the hatching of eggs that the idea of lime spraying was conceived, but at this season of the year the only thing is to spray as soon as the trusses open, either with a nicotine solution at the rate of 1 1-5oz. to ten gallons of water, or else the old-fashioned mixture of quassia and soft soap, which is formed by boiling 1lb. of quassia chips for fifteen minutes, dissolving ½lb. of soft soap, straining and making up with water to ten gallons. It may also be added that there are several good proprietary in-

CODLIN MOTH (CARPOCAPSA POMONELLA) WITH CATERPILLARS.
Much enlarged.

secticides on the market, which are valuable for destroying sucking insects.

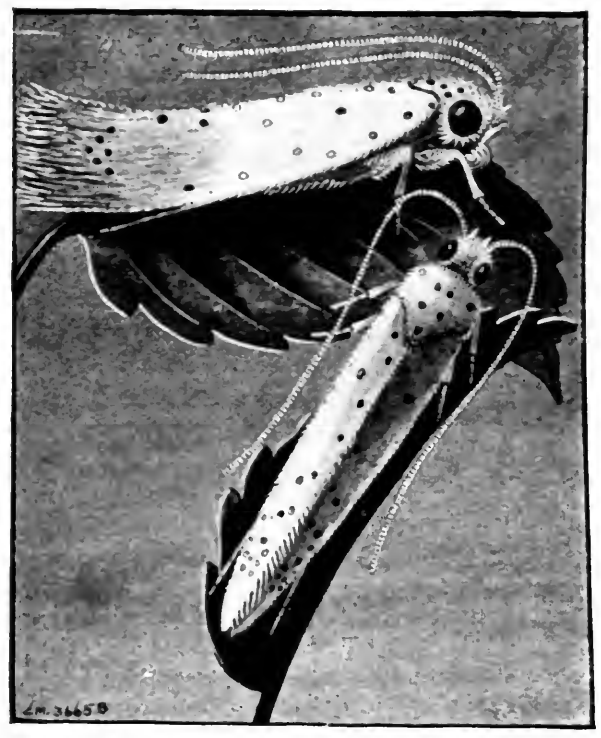
American Blight.—There is no need to describe the woolly aphis, because most people are only too familiar with its unwelcome appearance. With the approach of warm weather it becomes more active, and the white patches on the twigs more numerous. American blight is injurious to all apple trees that it attacks, but to young specimens it is fatal, and there is no remedy so good as direct application of an insecticide with a brush. I have found petrol, applied with a small brush, to be as good as anything for promptly putting an end to colonies of American blight.

Apple Aphides.—The worst of these is the leaf-curling aphis (Aphis poma), and last season it did an enormous amount of damage in orchards and plantations, causing leaves to curl up and fall off, and indirectly preventing the development of the fruit. Spray early is sound advice in reference to aphis before the pests have multiplied in numbers, and are safe inside the curled-up leaves. The remedies suggested for apple sucker may also be employed for aphis, but insecticides must be applied while the insects are exposed.

Winter Moth Caterpillars.—The eggs of the winter moth mostly hatch in March and early April, so that when the buds begin to open the little dark caterpillars are ready to feed upon them. As the caterpillars feed they grow bigger until by June, when they are mature, they are over an inch in length, and finally they descend to the ground. In some districts the winter moth pest has been reduced considerably by grease-banding, but when the caterpillars are feeding spraying must be resorted to. When the caterpillars are small they may be destroyed by a contact wash, and I have found a proprietary insecticide called Katakilla to be very effective, and it is non-poisonous. Another way of dealing with caterpillars is to poison their food by spraying before the flowers open, and again, if necessary, after the fruit is set, with arsenate of lead, which should be bought in the form of paste, and mixed according to the directions supplied with it.

Codlin Moth.—Most people are familiar with grubby apples, the tell-tale holes in the side of which denote that the grub of the Codlin Moth has been feeding therein. The egg is laid on the fruit as it sets, and the maggot, on hatching, enters the apple at the eye, bores its way to the core, and there feeds until its appetite is appeased. The remedy at this time of the year is to spray with arsenate of lead after the blossom has fallen, to poison the larvæ when they taste the arsenic that is deposited in the eye of the young fruit.

Tent Caterpillars.—Living in web nests or tents at the ends of shoots, the caterpillars of the Lackey and small Ermine Moths can quickly consume a good deal of young foliage. As they feed in colonies



SMALL ERMINE MOTH.
(Hyponomenta padellus.)
Much enlarged.

these pests are easily detected, and the best remedy is to cut off the shoot containing the web nest and burn it.

Apple Blossom Weevil.—In the apple orchards in the West of England this pest

appears to be on the increase, and the presence of the grub feeding on the organs of the flower is detected by the petals, which turn brown and curl inwards. No effective remedy has yet been discovered, but to cleanse the trees by means of lime-spraying in the winter is a good preventive.

Enemies of Pears.

Some of the pests mentioned above, notably the Winter Moth caterpillar, are injurious to pears, and the same remedies should be applied. Amongst other enemies are the following:

Pear Midge Grub.—This is undoubtedly the worst pest of the pear, and its unwelcome presence is detected by the fruits, which swell ahead of the others and grow much faster than sound specimens. When cut open, these swollen fruits are found to contain a number of small white maggots, which do the damage. An effective remedy has yet to be found for the pear midge, and the best thing is to pick off the infested fruitlets while the maggots are inside and burn them.

Slugworms. — These repulsive-looking pests occasionally skeletonise the foliage of pear trees, and when they are seen doing damage the best thing is to spray with arsenate of lead

Pear Leaf Blister Mite.—This pest is a relation of the dreaded "big bud" on the black currant, and blister-like galls on pear leaves indicate its presence. Not much can be done with it in the summer, but a good preventive is lime-sulphur wash, applied before the trees break in the early spring.

Plum Pests.

Here, again, we have a victim of the Winter Moth and several other members of the leaf-eating fraternity, but sucking insects are the bane of plum trees.

The Leaf Curling Aphis (A. pruni).—There is little need to describe this insect, because "blighted" plum trees are familiar to everybody. The aphis hatches out when the buds burst, and the pests multiply at a rate that is beyond conception. The remedy consists of spraying with an insecticide suitable for destroying sucking insects before the pests are safely curled up in the leaves.

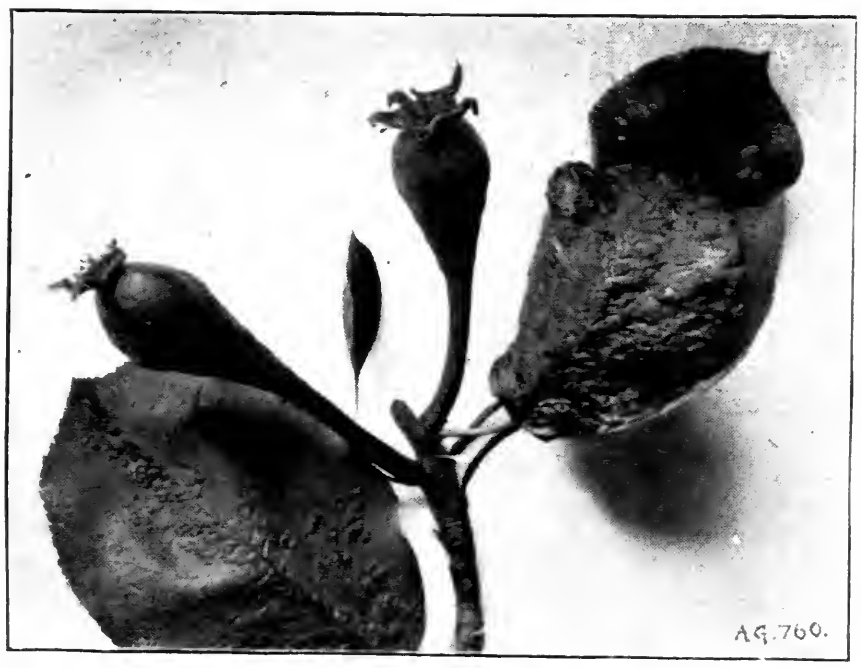
The Mealy Plum Aphis.—A mealy mass under the plum leaves denotes the presence of this pest, but it does not curl the foliage. It is generally in June and July that the mealy plum aphis appears, and it may be destroyed by mixing 4oz. of liver of sulphur with 25 gallons of quassia and soft soap solution. The latter alone is not effective.

Plum Shot-hole Borer.—Dozens of fruitful plum trees die every year through the above pest, which tunnels underneath the bark and into the wood, mostly on the stems. Badly affected trees should be burnt in the winter, and the only preventive remedy is lime-spraying the stems or smearing with some greasy substance like soft soap.

Enemies of the Cherry.

Various caterpillars, including that of the Winter Moth, make a prey of cherries, the pear and cherry slugworm does some damage, and occasionally trees are killed by borers, but the worst pest of this delicious fruit is the

Cherry Aphis or Blackfly (Myzus ribis).—As most people must have noticed, when the tips of cherry shoots have been badly affected by the above pest, they turn brown and die, while the honeydew from the aphis covers the fruit and spoils it. The insecticides recommended for sucking insects should be applied, but spraying should be done forcibly, and before the pests are curled up in the leaves.



PEAR-LEAF BLISTER MITE (ERIOPHYES PYRI).
Leaves of pear tree injured by mite.

Pests of Gooseberries and Currants.

Gooseberry Sawfly (Nematus ribesi).—The larvæ of the sawfly frequently attacks gooseberries, and sometimes currants, and there is none of the leaf-eating pests that can defoliate bushes more quickly. Dusting with hellebore powder is generally recommended as the remedy for this pest, but this is poisonous, and if the bushes are sprayed while the larvæ is small they can be easily destroyed with insecticides that will kill aphis.

Gooseberry Spider (Bryobia nobilis).—These diminutive pests not infrequently change the colour of gooseberry leaves from a bright green to a dull grey, and the effect of a bad attack is that the foliage falls off. A proprietary insecticide suitable for red spider may be applied for this pest or a home-made paraffin emulsion used.

Magpie or Currant Moth (Abraxus grossulariata).—The larvæ of this moth feeds on the young leaves of gooseberries, and sometimes on those of red currants, and should be dealt with in the manner described for the sawfly.

Aphis.—Not infrequently is the fruit on currants made sticky and dirty through the presence of aphis on the leaves, and it is not unusual for black currants to become leafless after an attack of the same pest. As in other cases of sucking insects, the thing is to prevent development by prompt and early sprayings with suitable insecticides of the type recommended.

Currant Shoot Moth (Incurvaria capitella).—These pests hibernate in crevices near to buds, and in the spring they emerge and enter the buds, afterwards making tunnels up the shoots, which flag and die. The best remedy is to watch and pick off the flagged shoots before the enemy makes its escape.

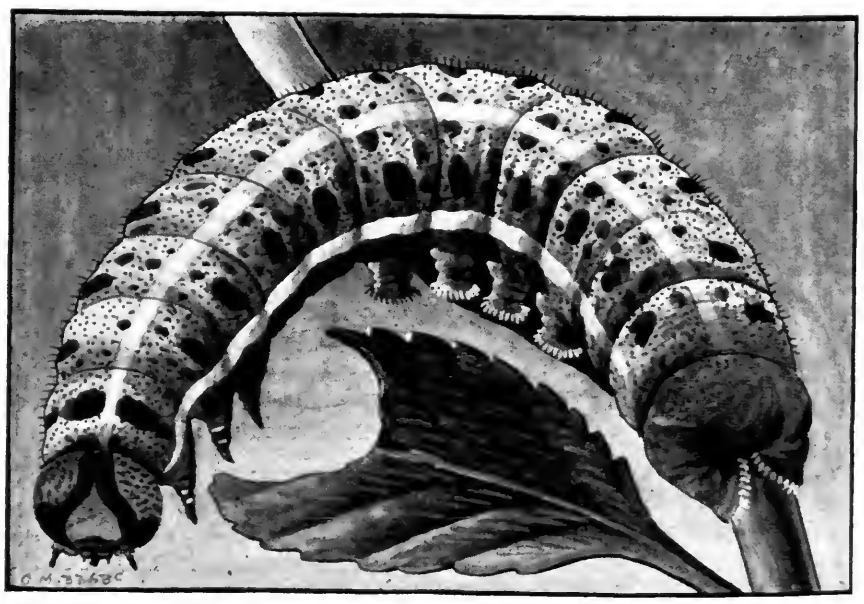
Big Bud.—It is too late now to commence the soft soap and quassia spraying that are recommended for big bud, but it is hoped that some readers of The Gardeners' Magazine are following the advice given in respect of spraying that was given in a special article a few months ago.

Raspberry Foes.

Raspberry Weevil (Otiorhynchus picipes).—Unfortunately there is no effective remedy for this pest, which appears in May, other than trapping with old bags placed about on the ground, under which the weevils collect.

Raspberry Beetle (Byturus tomentosus).—The larvæ of this pest lives in the core of raspberries, loganberries, and blackberries, and they can be frequently seen through the glass after these fruits are bottled. The beetles also eat the buds and various parts of the blossoms before laying their ova in the latter. This beetle is a great pest, and perhaps the best remedy is that of shaking off the beetles to prevent the damage done by the larvæ.

Raspberry Moth (Lampronia rubella).—The red caterpillars of this pest do damage by destroying buds and boring their way



CATERPILLAR OF LARGE WHITE CABBAGE BUTTERFLY.
Much enlarged.

Passing on the small fruits that need attention in the summer season, we have the

up the shoots, which afterwards die. Very little can be done with it at this season, and in the case of a bad attack, the old canes should be cut out early in the autumn and burnt.

Strawberry Ground Beetles.—Sometimes these night-feeding beetles do damage on strawberry beds by eating the skin and seeds of ripening fruit. The best way to eradicate them is to sink pudding basins in the ground baited with pieces of meat. The beetles fall into the basins, and are then captured.

Insect Foes in the Kitchen Garden.

Though the insect pests in the vegetable garden are neither so numerous, nor, perhaps so destructive as amongst the fruit, they are nevertheless a source of anxiety at this time of the year, and gardeners must always be on the alert to check their depredations. Some of the most troublesome of vegetable pests are described below.

Aphides.—The sucking insects find food to their liking in the kitchen garden, and what grower of broad beans is not familiar with the black aphis which appears every year at the tips of the stems? Early sowing is the best precaution against the bean aphis, for it is late-sown plants that suffer the most, and the next thing is to promptly pinch out the points of the shoots and burn them as soon as the aphis makes its appearance. In bad cases syringing with quassia and soft soap solution may be resorted to, but this is rarely necessary if the pinching is not neglected. It is not unusual for members of the cabbage family to be infested with an aphis, particularly on light and poor soils, and if this happens, an insecticide should be promptly applied. Attack early is, in fact, the rule with all aphides in the kitchen garden.

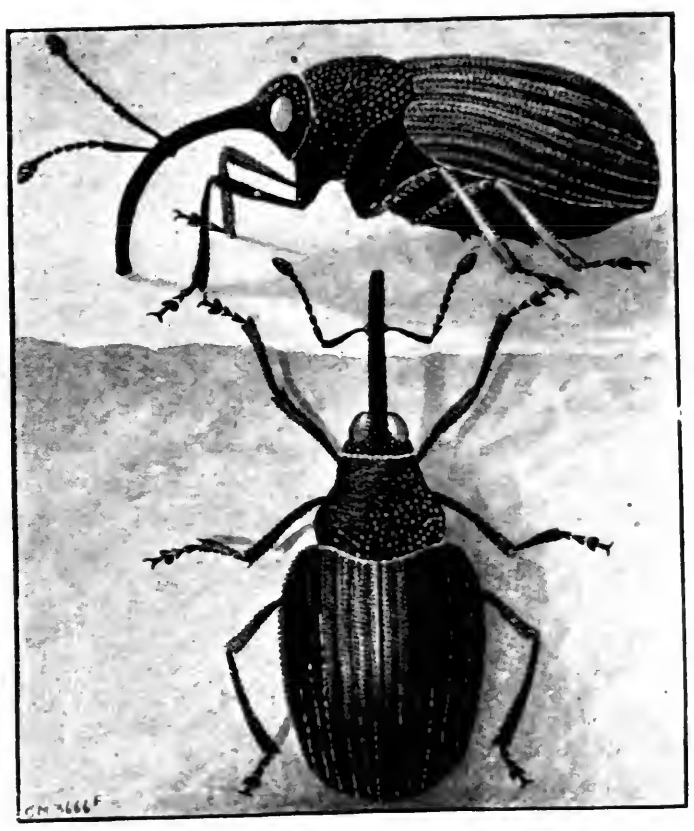
Weevils and Beetles.—A great nuisance in some gardens is the little asparagus beetle, which feeds on the tender parts of asparagus plants, doing a lot of damage. The pests are not easy to eradicate, and dusting the plants with freshly slaked lime is one of the best remedies. The cabbage gall beetle is another common pest, and most people are acquainted with the galls which protect the grubs of the beetle, and are found on the stems of all kinds of greens just below the ground. Where this pest is very prevalent, ground intended for brassicas should be dressed with Apterite, Vaporite, or Grubicide, and their root stems before planting should be dipped into a thick puddle of lime, soil, and water, which helps to make them distasteful to the beetle.

No pest in the garden is more persistent than the little turnip flea beetle, which devours in a wholesale manner all members of the brassica tribe when in a seed leaf stage. The turnip flea laughs at insecticides, and it is best thwarted by quick growth of the plants out of the seed leaf stage. Sow turnips and greens, therefore, in showery weather, if possible, and if it is dry, fill the drills with water previous to sowing. Dusting young seedlings with very fine, dry, road dust in the early morning helps to keep off the flea, and some people pin faith in damping the seeds with turpentine prior to sowing. A common pest that is not very easily detected, owing to its colour being similar to that of the soil, is the little pea weevil, which eats round the edges of the young leaves of peas and checks their growth. Dustings with soot and lime to make the plants distasteful to the pest are good, but as the peas get up above the ground they grow out of harm's way.

Leaf-mining Insects.—The worst of this family is the celery fly, which deposits its eggs under the cuticle of the celery leaf, and the presence of the maggot feeding therein is indicated by blisters and brown patches on the leaves. Making the leaves distasteful to the fly by syringing with soap and quassia solution, and dusting with soot are the best preventives, and if the attack is not severe it may be checked by crushing the maggots in the leaf between the thumb and finger. Sometimes parsnips suffer through a leaf-mining grub, particularly in dry seasons, but it is only in extreme cases that severe damage is done.

THE ASPARAGUS BEETLE.
(Criocaris asparagi.)
Much enlarged.

Grubs.—The grub of the carrot fly is troublesome in some gardens, and it is in the early summer that the fly deposits her eggs on the roots of the carrots when young. The grubs do damage by burrowing their way into the roots. The only practical remedy is to make the plants distasteful to the fly, and a good means of doing this is to scatter a little sawdust or wood ashes that have been saturated with paraffin on the ground between the rows, first when the carrots are coming up, and later when they are nearly big enough to thin. On light and sandy soils the grub of the onion fly is the bane of this crop, but on retentive mediums it gives much less trouble. Firm soil and early sowing are preventives, but now that the fly is on the wing the only course is to prevent egg-laying by making the plants distasteful to the insect. The remedy suggested for carrots is one means of effecting the above purpose, another is syringing with soapy water, a third liberal dustings with soot, and a fourth is to keep the soil well trodden to the onion plants. Stimulating fertilisers should be given to help the plants to grow away from the pest, and every affected plant should be drawn out and burnt. It is during May and June, and during the early stages of the growth of onions that precautions against maggot are most essential.



CABBAGE GALL WEEVIL.
(Ceutorhynchus sulcicollis.)
Much enlarged.

General Pests.—The wireworm, particularly on newly-formed gardens, the leather-jacket grub, sometimes the cockchafer grub, and slugs galore are amongst the pests that have cosmopolitan tastes, and feed on a variety of crops. The catch-and-kill remedy is, perhaps, the best in all the above cases, and the kitchen gardener must be ever on the alert for the common enemies that seek to satisfy their appetites on cultivated crops during that critical period which connects infancy with the stage of maturity. G. H. H.

PROPOSED FORESTRY AREA IN SCOTLAND.

The announcement that the choice of the Advisory Committee on Forestry for a demonstration area in Scotland is likely to be on the estate of Ballogie in the valley of the Dee, Aberdeenshire, has given great pleasure in the north. The feeling predominates, however, that the choice must not be looked upon as favouring in any special manner the Aberdeen School of Forestry, but rather as a striking instance of the very best available area being chosen. Ballogie has over 4,000 acres of woodland, and is thoroughly characteristic of Scottish sylviculture. It is well sheltered, the climatic conditions are excellent, the soil good, and the crop of timber is at all stages of growth. The woods have been admirably managed for generations, and the present head forester—Mr. George Wyllie—has been at his post for nearly half a century. Mr. Wyllie introduced a system of rotation by which woods may now be found on the estate in various stages of growth, and always some ready for cutting and made commercially valuable. Indeed, the area proposed is recognised by the most competent authorities as being one of the finest in Scotland, its configuration, soil, and, above all, the capital crops of Scots fir and other trees, making the choice an ideal one.

When the members of the Royal Scottish Arboricultural Society chose Aberdeenshire as the venue for their annual excursion in June last year, they were greatly impressed with the sights they saw on Ballogie. Sir John Stirling-Maxwell, Bart., of Pollok, the president of the society, was simply charmed with what he saw here, and spoke very highly of Ballogie woods. The following measurements and ages of some of the trees the Scottish arboriculturists saw during their visit last June will give some idea of what is to be found on the estate of Ballogie. Be it noted that all circumferences are measured at five feet from the ground:

	Height Ft.	Circum. Ft. In.	Age Yrs.
Abies lasiocarpa	74	5 10	50
A. nobilis	77	6 11	58
A. Nordmanniana ...	74	9 0	58
Picea sitchensis	74	5 10	50
P. Douglasi	97	10 0	58
P. Douglasi	108	9 5	58
Sequoia gigantea ...	74	11 3	50

Numerous other areas in Scotland were examined, but were found to be either unsuitable or not available. W. K.

TRIAL OF SPRAYING MACHINES
AT WISLEY.

That the importance and necessity of spraying fruit trees, roses, and potatoes has become more generally and fully realised than was hitherto the case requires no stronger proof than is afforded by the rapid increase in the number and variety of patterns of spraying machines placed on the market.

FOUR OAKS "BATTLE" SPRAYING MACHINE IN USE WITH WATER.

Improvement in construction, greater adaptability to various purposes, and higher efficiency have been obtained in the case of the older makes of machines, and there are also so many new patterns that it is certainly not a simple matter to decide definitely that this machine or that is the best of all. Indeed it is very much open to question whether any one machine merits such a distinction, for spraying is an operation that has to be performed under so widely differing circumstances and conditions that one machine may be ideal for one purpose, whilst another is equally satisfactory under other circumstances. It is therefore fully in accordance with our views that at the trial of spraying machines and appliances conducted by the Royal Horticultural Society at Wisley on Wednesday, April 24, each individual machine was considered entirely on its own merits rather than in competition, and the awards made simply testified to the excellence of the appliance without suggesting that it was in every way superior to all other machines. There is real practical value in such a demonstration as that which was held by the R.H.S., and it seems a pity there was not a larger attendance of growers to witness the trials. The Rev. W. Wilks, Mr. S. T. Wright, and Mr. Gaskell attended to control the arrangements, and the seven gentlemen who acted as judges were Messrs. F. J. Chittenden, S. T. Wright, Hy. Hooper, Cecil H. Hooper, E. S. Salmon, H. M. Lefroy, and C. R. Fielder, whilst Dr. Williams and Mr. E. Mawley represented the National Rose Society.

Judging.

A word of praise is due to the judges for the patient and painstaking manner in which they investigated every detail of the machines brought before them, but it occurred to us that the demonstrators would have been rather more at their ease if they had appeared before the judges separately, unaccompanied by the rest of the exhibitors. Naturally enough, if a manufacturer has introduced some improvement or new device into his machines, he hesitates to explain in full detail its construction and capabilities whilst in the company of competitors. However, there was evident a most friendly feeling among the exhibitors as well as the rest of the company, who had a delightfully fine, warm day for their visit to the Wisley Gardens. Roughly, the exhibits might be classified under three headings: 1, Syringes and small hand sprayers for greenhouse use; 2, knapsack sprayers; and 3, large machines on carriages or wheels. The necessary qualifications of an efficient spraying machine may be briefly stated to be sound, but simple construction, accessibility of working parts for purposes of cleansing or repair, ease of working, immunity from damage by such acids as are contained in caustic washes, nozzles that will produce fine, even spray, whilst allowing such mixtures as lime-wash or soap and oil to pass through without clogging, durability, and portability. The trials afforded conclusive proof that even the finest nozzle capable of allowing anything in the way of a mixture to be used will not give a spray that will really cover the whole surface of a plant. True, several of the machines produced a beautifully even and mist-like spray, but when lime-wash was discharged on to sheets of brown paper, it was plainly seen that the paper was thickly spotted with the fluid, but not really covered. This is a matter of importance, as showing the absolute necessity for spraying more than once. It is useless, indeed detrimental, to tarry sufficiently long upon a tree to ensure the surface being absolutely covered, for that will lead to running of the liquid and probable scorching of the parts where the heaviest coating is received.

Another point that impressed itself upon one was that for all but the biggest work a knapsack sprayer is really the handiest and most useful machine, because any sprayer on wheels not only occupies enough room to make it awkward to get about between rows of trees, but is, when filled, so heavy that it requires at least a couple of men to drag it over rough ground, and even with two men the task is a laborious one.

Of course, very large machines for use in large orchards, potato fields, or hop plantations are built on carriages to be drawn by a pony or donkey, and there are even a few motor-driven machines on the market, but none were brought forward at Wisley.

Knapsack Sprayers.

Of the knapsack sprayers we were very much struck with an upright cylinder machine shown by Messrs. Hartjen and Co.,

"ALPHA" CONTINUOUS SPRAY MACHINE DISTRIBUTING ARSENATE OF LEAD WASH.

35-37, Noble Street, London, E.C. It is a strong, well-devised machine, made of a brass alloy that will resist corrosion from acids, and is therefore suitable for spraying caustic soda, arsenical washes, or lime-sulphur spray. Its parts are simple, the principle of working being by means of compressed air, a pump being fixed in the machine for purpose of charging. The valve is a solid rubber core, held by a strong spring, either of which is easy of replacement. The machine is strongly riveted, and is not excessively heavy, the total weight when holding three gallons of fluid, and charged for use, being about 45 lbs. Each machine is fitted with a pressure gauge, which certainly makes for safety, although, considering the machines are tested to withstand 300 lbs. pressure per square inch, there is little risk of accident. Fitted with good nozzles this machine did excellent work.

Messrs. Hartjen showed an apparatus for charging several sprayers simultaneously with both fluid and air by what they term their battery system, which should be useful where several machines are in use.

Another machine working on the pneumatic principle was the Alpha, exhibited by Messrs. Robinson Bros., Lim., Ryders Green, West Bromwich. This machine has no interior working parts, it being simply a cylinder of lead-coated steel, which, after being two-thirds filled with liquid, is charged by an ordinary bicycle tyre pump, eighty to a hundred strokes sufficing to fully charge the machine. The Alpha is fitted with capital nozzles that produce an extremely fine, mist-like spray. The great advantage of a pneumatic machine is that the operator has both hands free for directing the spray, since there is no continuous pumping to do.

A new and improved pattern of the well-known Four Oaks machine was shown by the Four Oaks Spraying Machine Company, Sutton Coldfield. The usual copper tank is fitted with a detachable inner lining of tin, making the machine acid proof. Air chamber and pump are outside the tank, and therefore easily accessible, and the pump is fitted with an angled arm, which passes over the operator's shoulder to be worked from the front instead of at the side. It is at the best a fatiguing task to pump continuously with a side pump, and the over-shoulder pump is calculated to simplify the task. One of the R.H.S. students, who operated the machine, expressed preference for this over the older side-pump pattern, which he had recently been using. Messrs. Cooper, Pegler, and Co., Christopher Street, Finsbury Square, showed the Vermorel knapsack sprayer, which, of course, was the first of the sprayers introduced to this country, and has for nearly a quarter of a century proved a highly satisfactory machine. They showed a copper machine, lined and covered with tin, and an agitator has been fixed to the pump, and an additional strainer put into the lance. A machine of similar type in copper was shown by Messrs. E. A. White, Lim., Paddock Wood, Kent, under the name of the Abol sprayer. Nozzles such as are used on the Abol syringe are attachable to the lance on this machine.

MESSRS. G. AND W. PURSER'S PUMP SYRINGE IN USE WITH LIME-WASH.

MESSRS. HARTJEN AND CO.'S "HOLDER" PNEUMATIC KNAPSACK SPRAYING MACHINE IN USE WITH LIME-WASH.

Heavy Machines.

The first of the heavy machines to be set in motion was a new pattern of the Alpha. A cylinder similar to their knapsack is filled and charged, and, by a clever arrangement, this can be kept filled with fluid from an open tank on the carriage, so that, once charged with air, the pressure can be retained as long as desired. The tank is, of course, kept well filled by buckets, and a semi-rotary pump forces the liquid into the cylinder, an agitator attached to the pump keeping the mixture in proper suspension. The carriage stands on four broad-faced iron wheels, and is fitted with pony shafts. It is a machine capable of getting through a great amount of work, two 6ft. corrugated brass lances and two 20ft. lengths of stout rubber hose giving reach enough for hops or tall trees. Another big tank machine that aroused considerable interest was the Enots Utility, shown by Messrs. Benton and Stone, Bracebridge Street, Birmingham. A strong pump is fixed in the centre of the tank, with a strainer at its base. With each descent of the pump handle a circular brush passes over the strainer, so that sediment or powder is removed, keeping the gauze clean and in free working order.

Both jets of the long lances are under control of a handle on the tank, so that the man at the pump can turn either or both sprays off or on at will. An ingenious attachment to the nozzle automatically removes any obstruction from the jet by simply turning off the spray. The pump works very easily, and the only criticism of this machine we have to offer is that a more effective agitator is required to keep such mixtures as lime-sulphur or Paris green in suspension. The Four Oaks Battle machine is very useful, suitable for either garden, nursery, or fruit plantation. It consists of a strong oaken tub of narrow oval shape, slung on wheels after the style of a water barrow. The widest measurement, from the hub of the wheels, is 23 inches, so that it is of handy size for narrow rows or pathways. A double action pump forces the fluid up a central column branching at the top into two outlets. Armoured hose and long lances carry

the spray a good distance, and an effective agitator and good strainer are provided.

Hand Sprayers and Syringes.

There is a wide field of usefulness for small spraying machines that may be held in the hand. In greenhouses, for instance, and in gardens where a few roses are grown, sprayers holding about half a gallon are just the thing.

A good many of these small hand machines are on the market, and several were shown at Wisley.

The Hartjen hand spray de luxe is an excellent little machine, with an in-built pump and an automatic stop-cock or valve release, by pressing which the jet is opened for spraying without necessity for tap turning. The Vermorel hand sprayer in brass is similarly fitted with an automatic release. The Alpha hand sprayer is well known, and is a very serviceable sprayer, and another good machine shown was the Enots, made by Messrs. Benton and Stone.

A capital bucket syringe from Messrs. G. and W. Purser, Lim., 92, Hatton Garden, E.C., impressed us as being a very useful appliance. A syringe with a fine spray nozzle is attached by a length of hose to a hand-pump, which is placed in a bucket. At the base of the pump standard is a fine copper gauze strainer. It is a double-action pump, and very easily worked, and for such work as disinfecting or white-washing is equal to the more expensive knapsacks, whilst, of course, the continuous spray obtained by means of the pump places the appliance far in advance of the ordinary syringe except for work among pot plants or in small conservatories.

For all such small work the Arnol syringe, shown by Messrs. Purser, is excellent. By means of a double-nozzled cap, a spray is obtained, either discharging straight ahead or at an angle in an upward direction as may be desired, there being no elbows to attach for the purpose. A brass ball in the cap automatically closes one jet whilst opening the other, and by turning the syringe in the hand the jets may be opened alternately giving straight-ahead spray for surface and upward spray for under-parts of the plants. An assortment of nozzles giving sprays of varying scope and density are obtainable, and these are so made that cleaning entails a minimum of trouble.

It is unnecessary to go into details of the merits of the familiar Four Oaks undentable syringe, which are made for strength and durability, having a corrugated brass casing that effectively prevents damage to the inner tube of the barrel, and the nozzles supplied for these syringes are capable of producing either forcible or fine, mist-like spray.

The Abol syringe, brought by Messrs. E. A. White, Lim., Paddock Wood, are also so widely known and generally popular that comment on their excellence and utility would be superfluous. The Boundary Chemical Company, Cranmer Street, Liverpool, showed a hand-worked syringe, with a hose inserted in the middle of the barrel. By simply placing the hose in a bucket and working the plunger to and fro in the ordinary way, the liquid in the bucket is syphoned through the syringe, discharging through a very fine nozzle with a neat, swan-necked bend, by which the spray can be directed in any direction desired.

Altogether the whole of the appliances brought forward were of practical and useful character, and whether for small or extensive operations it was made abundantly evident that growers need experience no difficulty in obtaining machines suited to their needs.

Official Report of the Trials.

Under the arrangements made by the Council of the Royal Horticultural Society for the trial of horticultural sundries this year, a special trial of spraying machinery apparatus was organised. It took place at the society's gardens at Wisley on Wednesday, April 23. The following are their recommendations, which have been approved by the Council:

Syringes. — Commended: Purser's Arnol Sprayer, No. 2; and Corry's Syringe. Award of Merit: Four Oaks' Undentable (Angle Bend excluded); and Abol Syringe, E. A. White, Lim.

Bucket Sprayers.—Award of Merit: Boundary Company, Demon Continuous Spray Bucket Syringe.

Continuous Pumping Knapsacks.—Highly commended: Four Oaks' Centre Knapsack Pump. Award of Merit: Abol, E. A. White, Lim.; and two Continuous Knapsacks, Eclair No. 1 and Etame, Cooper, Pegler, and Co. Commended: Benton and Stone's Continuous Pumping Knapsack.

Large Pneumatic Sprayers.—Highly commended: Hartjen Battery Filler and Holders.

Large Continuous Pumping Sprayers.—Highly commended: Four Oaks' Large Continuous Pumping Battle Sprayer. Commended: Utility, Benton and Stone.

Hand Diffusers. — Highly commended: Alpha Hand Diffuser, Alpha Extinguisher Company; and Hand Diffuser No. 1,807, Benton and Stone. Commended: Vermorel Hand Diffuser, Cooper, Pegler, and Co.; and Holder Hand Diffuser, Hartjen.

Note.—Four Oaks' Nozzles, highly commended.

The Judges considered the provision of means of carrying accessory nozzles on the hand syringes would be a great improvement. None had such a provision. In using some spraying materials the provision of a strainer on the intake nozzle would be an advantage.

W. WILKS, Secretary.

INSECT ENEMIES UNDER GLASS.

The "indoor gardener" usually looks upon only five kinds of insects as enemies to be seriously considered and combated with. These are mealy-bug, red spider, aphis, thrips, and scale insects. Such other insect enemies as the "leaf-miners," bulb mites, cockroaches, crickets, weevils, etc., are, more or less, "casuals," and it is only rarely that preventive measures are taken. Injurious insects are of two types, sucking and biting, and it will be noticed that the five "habituals" are all sucking insects, and of these the red spider and thrips may usually be said to be the penalty of bad cultivation, although in palliation or excuse it may justly be said that attacks of red spider are often encouraged by the structural faults of the glass-house. Many of us have had, at various times, to deal with houses which are "terrors for spider." It is interesting to notice that whereas nearly all fungoid diseases are primarily due to errors of cultivation—including over-feeding and intensive propagation—most of the insect enemies are present, and increase and multiply, ravaging the plants through neglect, not necessarily on the part of the "present cultivator."

There are gardeners who, wisely perhaps, refuse to acquire, by purchase or otherwise, any desired new or favourite plant for fear of also obtaining undesirable entomological specimens. In this connection some nurserymen are offenders; the plants which such dealers distribute are generally superficially clean, but a close examination will often discover potential pests.

Many old glass-houses are veritable incubators of plant pests, and no matter how clean the gardener may endeavour to keep his plants they are quickly infested with a fresh stock. Failing entire destruction of such glass-houses the only remedy is to thoroughly cleanse them. If all the growing plants can be transferred to another structure, the old-time method of fumigating the house with burning sulphur is very effective. Stop all the crevices of the woodwork with putty and repaint. The supporting walls of greenhouses are often fertile sources of insects, and this portion of the house does not always receive proper attention. If the pointing of the brickwork is ineffective, this should be remedied, and all interior walls thoroughly treated with hot lime-wash at least once a year. When preparing the lime-wash some gardeners add a handful of sulphur in the hope of checking red spider, but the inwardness of this practice is not readily apparent, for when so placed it is only the sulphur fumes which could possibly have any effect, and, as we know, for this heat is necessary. Even if the sulphur did become sufficiently heated to dissipate fumes, the quantity would be totally inadequate.

As already suggested, insects injure plants, either by sucking their juices from the leaves and stems, or by eating various portions. As most of the sucking insects obtain their food by boring into the tissues of the host, we cannot kill them by spraying their food with poisons, as is practicable with the biting insects, although they may be killed by caustic or poisonous sprays, but as there are few indoor plants which will stand these corrosive liquids, their use is reserved for the hardier fruit trees.

Cleanliness and good cultivation are the best preventives of attacks of many insects, but there are others which persist in spite of the most approved methods, and for these remedies must be used. Formerly, the most common method of destruction was that of suffocating the insects by tobacco smoke. The smoke being obtained from smouldering, nicotine-saturated paper or rag, and as it is essential that it should not burst into flame, the operator was forced to remain in the house alongside the fumigating vessel. Nowadays, the young gardener is more fortunate, the introduction of fumigating compounds having rendered his task much more pleasant, and tobacco paper has been banished in most gardens in favour of nicotine compounds. But this method has its limitations, and when the apparatuses become improved cyaniding, as fumigation by means of hydrocyanic acid gas is termed, will be more generally practised, and our glass-houses will be easily rid of insect pests.

Sucking Insects.

Of this class the most insidious are red spider and thrips, which, on account of their small size and habit of feeding on the undersides of the leaves, frequently obtain a disastrous footing before their presence is suspected. Certain plants, e.g. Indian azaleas, begonias, gloxinias, palms, vines, and the like, are especially susceptible to attacks of red spider and thrips, which are generally found in company. Their presence is soon indicated by the unhealthy, thin, drvish yellow colour of the leaves, and, as these tiny insects increase rapidly, the affected leaves are quickly rendered useless to the plants; indeed, as in the case of the azaleas, the plants are often entirely defoliated, so that preventive measures are especially required. Fortunately, these are quite simple, and consist of keeping the atmosphere of the house and the surroundings of the plants uniformly moist, and of frequently syringing them, particularly directing the spray of water to the under-surfaces of the leaves. Of the various remedies, fumigation with tobacco compound, cyaniding with hydrocyanic acid gas, and spraying or sponging the foliage with tobacco water may all be recommended for general use. With such plants as orchids it is usual to sponge the leaves with soapy water.

Mealy-bug very soon makes its appearance, and the white, woolly collections are

Orders over 5s. carr. paid. List of Fancy Nets free. Write for Flag List. H. J. GASSON, Net Works, Rye. Est. 126 years.

too often seen on indoor plants. This insect is a coccid, and is closely related to the scale insects, but luckily it lacks the hard scale covering and limpet-like power of attachment. Like the red spider and thrips it affects a large number of plants, but it chiefly confines its attention to those growing in warmth; the genera it seems to prefer are such as acalypha, eucharis, gardenia, stephanotis, and vitis. On the eucharis it settles down on the undersides of the leaves near to the edges, which curl inwards as though to form harbourage, whilst on most other plants the mealy-bug usually preys on the bases of the leaves near to the stalk, probably so as to more easily obtain plenty of food. The plants with woolly or with hairy leaves are the most difficult to cleanse, and these also most quickly show signs of distress. Badly affected pot plants should be laid on their sides and forcibly syringed with petroleum emulsion. Sponging the leaves with soapy water may be resorted to when treating moderately smooth-leaved plants, but in no case should the sponging mixture contain petroleum. The application of methylated spirit with a soft brush is a very effective method of killing mealy-bug, especially when it is lodged in cracks of bark.

There are very many kinds of scale insects which are injurious to plants grown under glass, which are only distinguished by minute structural characters. But, however, a knowledge of the different genera and species is not necessary for the gardener, as they are all much alike in their depredations, and the same remedial measures are applicable. It is only the wingless female insect which is generally known, the winged males, as a rule are few in numbers, very minute, and exceedingly short-lived. The females are developed from larvæ which have three pairs of small legs to enable them to reach suitable feeding places. They at once bore their beaks into the leaf or stem, and settle down there for the rest of their lives: the legs and antennæ disappear, and the larvæ metamorphose into the familiar rounded insect.

The persistent habits of the female scale insects render their eradication a troublesome matter. Ferns, palms, cycads, and orchids are the names of a few kinds of plants more generally affected by the scale insects, but they are common, though fortunately in a lesser degree, to many others. The soft and easily bruised fronds of most ferns prohibit the successful employment of many remedial methods, and when ferns are badly affected it is best to entirely remove and burn the fronds, then to thoroughly cleanse the pots, and top-dress with fresh soil. With other plants the scale insects may be destroyed by repeated syringing with kerosene solution at twenty-four hour intervals, or with strong tobacco water. Sponging with soapy water is useless unless the insects are first loosened.

Aphides are the most rapidly increasing plant pests of all. The gardener does not concern himself with the vexed question as to whether there really are, as some authorities contend, different species of aphis for each different genus of plants. He is satisfied to know that "fly" may be conveniently divided into three classes: green-fly, black fly, and white fly, and that the same remedial measures are applicable to the members of a class. Perhaps more than any other insect the "green-fly" confines its attentions to the young and succulent shoots, and consequently the harm done is great. As a summer enemy of the plantsman, the greatest ravages are on the plants of the greenhouse and frames, and the only really effective prevention is regular fumigation. Water forcibly applied with a syringe will do much to keep green-fly in check, but with pot plants the use of so much water is objectionable. Quassia extract renders the foliage distasteful to the insects, and this bitter property remains for a fair time. The best method of preparing the quassia solution is by well boiling one pound of chips in a quart of water, adding, whilst hot, one pound of soft soap; diluting for use with four gallons of water. Tobacco water is also effective, but it should not be used on plants with hairy or woolly leaves, nor should it be allowed to remain on the plant long enough to stain the leaves. With such plants as chrysanthemums, in which the fly congregate in the growing point, it is always well to periodically dust them with dry tobacco powder.

The female cattleya fly lays her eggs in the bases of young growths in the spring and during the early summer the broods of larvæ live on the juices of the plants. Fumigation at frequent intervals, so as to kill all the fly as they emerge from the pupal stage, and so prevent their increase, is the best remedy.

The bulb-mite, which was recently discussed in an article on Eucharis grandiflora, is common to that plant, hippeastrums, and allied genera. The present writer is decidedly of the opinion that their presence is due to errors of cultivation, and in bad cases would counsel cremation. In milder instances, it would be worth while to try vapourising with carbon bisulphide, and, as lime is said to be very distasteful to the white mites, the bulbs should be washed in lime water.

Biting Insects.

Luckily, the summer insects which eat portions of plants are not so troublesome to the gardener under glass. To combat these it is in many cases possible to poison their food, but as a general rule the grower prefers hand-picking when dealing with the day-feeding insect larvæ.

Cockroaches and crickets often do much damage to glass-house plants; the former insect prefers tropical heat and rarely invades the cooler houses. The roots, as well as the growths, of many orchids are freely eaten, and the young flower scapes of the eucharis are another favourite food. The out-of-the-way parts of the houses, especially around the hot-water pipes, should be kept scrupulously clear so as not to leave harbourages for the obnoxious insects; and, as they prefer absolute dryness, all likely places should be flooded with water daily. Poison, spread on small squares of stout brown paper or on bread, should be laid in their haunts every evening—they being nocturnal feeders—and gathered up in the morning. Phosphorus paste is very useful for this purpose, as also are several of the advertised preparations.

Weevils are also night-feeding insects, and, being comparatively small, their depredations frequently pass unsuspected. While the perfect beetle feeds on the fronds of ferns, and on the leaves of various plants, the greatest damage is done by their larvæ, which prey on the roots of such plants as ferns and palms. These yellow legless creatures have enormous appetites and eat large quantities of roots. It is always difficult to rid pot-plants of root-feeding pests without injuring the host. The mature insect may be caught on a sticky cloth at night; when disturbed they at once fall to the ground, so it only remains to place the plants on the cloth or on sheets of greased brown paper during the day time. The larvæ must be either picked out from amongst the roots with a sharp instrument or be destroyed by a vapourant.

CECIL AUBREY.

MACKAYA BELLA.

This, one of the larger-growing members of the order Acanthaceæ, forms a good-sized shrub, and was introduced from Natal in 1869. It is a very pretty flowering plant for the greenhouse, but in order to have it at its best it needs special treatment.

While it is benefited by a warm temperature in the spring and early part of the summer, it should, in August, be well exposed to sun and air in order that the wood may be thoroughly ripened. In winter only sufficient water must be given to keep the soil slightly moist, when, in spring, under the influence of additional heat and moisture, it will start into growth, and bloom usually about May. The flowers, which are borne in racemes, are bell-shaped, about two inches long, and of a pleasing shade of pale lilac. T.

THE BEST PERPETUAL-FLOWERING CARNATIONS.

The following selections have been compiled by the Perpetual-flowering Carnation Society from lists sent in by its members, and published in the official "Year Book":

Twelve Best Varieties for Profit.

May Day, 26 votes; Enchantress, 25; White Enchantress, 25; British Triumph, 25; Winsor, 21; Rose Pink Enchantress, 20; White Wonder, 20; Scarlet Glow, 19; Beacon, 18; Mrs. C. W. Ward, 17; White Perfection, 16; Lady Northcliffe, 14. Varieties which received over six votes: Gloriosa, 10; Britannia, 7; Carola, 7; R. F. Felton, 7. Twenty-seven commercial growers took part in the voting.

Twelve Best Varieties for Exhibition.

Carola, 23 votes; Scarlet Glow, 18; White Perfection, 17; Baroness de Brienen, 17; Mikado, 15; Enchantress, 14; Mrs. C. W. Ward, 13; R. F. Felton, 13; Lady Meyer, 12; White Wonder, 12; Gloriosa, 11; Marmion, 11. Varieties which received six or more votes: Benora, 10; Rose Pink Enchantress, 8; May Day, 7; Mrs. C. F. Raphael, 7; British Triumph, 6; Lady Northcliffe, 6; Sunstar, 6; Rosette, 6. Twenty-five commercial growers took part in the voting.

Twelve Best Varieties for the Greenhouse.

Enchantress, 19 votes; May Day, 19, Britannia, 17; British Triumph, 15; Carola, 15; Lady Alington, 15; Mikado, 14; Scarlet Glow, 13; White Wonder, 13; Mrs. C. W. Ward, 12; R. F. Felton, 11; White Perfection, 10. Varieties which received six or more votes: White Enchantress, 9; Baroness de Brienen, 8; Rose Dore, 8; Lady Northcliffe, 7; Winsor, 7; Rose Pink Enchantress, 7; Beacon, 6. Twenty-four gardeners and amateurs took part in the voting.

Twelve Best Varieties for Bedding Out.

Britannia, 16 votes; Mrs. Burnett, 13; Enchantress, 13; May Day, 12; Rose Pink Enchantress, 12; White Perfection, 12; Winsor, 10; Mrs. T. W. Lawson, 7; Mikado, 7; Beacon, 7; Mrs. C. W. Ward, 7; Rose Dore, 6. Sixteen gardeners and amateurs took part in the voting.

Epacris onosmiæflora flore plena.—This, which is also known as Epacris purpurascens, is remarkable among the members of this genus for its markedly double blossoms, which in the best forms are like little rosettes. In some individuals they are pure white, and in others of a bluish tint.—S. W.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CATTLEYA HOUSE.—Many of the autumn and late-flowering cattleyas, læliocattleyas, lælias, and brasso-cattleyas will now be in active growth, and must receive every encouragement. All plants in growth should be placed at the warmest end of the house, and where they will obtain the benefit of good light. Upon the proper ripening of the growths depends the quality of the flowers they are to produce. It is surprising the amount of light that is necessary to properly mature the growths of these late-flowering kinds. It is often more difficult than is the case with the spring-flowering kinds, and this is not surprising when we consider the amount of light obstructed, even with the most discreet use of the roof blinds and other shading which is necessary during the summer months. In addition to the question of flowering satisfactorily, there is still a more serious matter following on immature and sappy growth. Take as an example C. Warscewiczi, and the old type of C. Dowiana. If these have not matured their growths sufficiently to produce flowers, it is found a difficult matter to prevent a second growth commencing, and if this occurs towards the end of September it is found most unsatisfactory, and frequently diminished growths are the result.

WATERING.—Care must be observed in affording root moisture. Only sufficient is necessary to keep the plant plump and vigorous; any excess will destroy the roots. It is desirable to syringe, or rather spray, the plants overhead on fine days, and when the conditions are favourable.

REPOTTING.—Many of the plants that have passed out of flower may now be repotted if necessary. We use the usual compost of about two parts best fibrous peat and sphagnum moss, with some chopped oak leaves intermixed. We find that the Osmunda and Polypodium fibres are not suitable for our district, hence their use should proceed with strict caution. There is a considerable difficulty in obtaining good peat, but it is still procurable. The plants are potted firmly in this compost. All newly-potted plants must be shielded from strong light until the new roots have got hold of the fresh compost.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CAMELLIAS.—Plants growing in pots or tubs must be kept in a moist atmosphere until they have perfected their growth. Syringe them twice daily, and during hot, sunny weather damp down the walls and other bare surfaces in the house several times a day. Use fire heat sparingly, and when growth is completed give plenty of air, eventually placing the plants out of doors. Any repotting required may be done towards the end of June or early in July, using a compost of peat and loam in equal parts with a little coarse sand. It is very important that the pots or tubs be amply drained. Camellias are seldom free from white scale, and when badly infested with this pest, the only sure method of destruction is by sponging the leaves with soapy water. As a preventive, the plants should be turned on their sides occasionally, and syringed with a mixture of soft soap, and a little petroleum. Before placing camellias outside fumigate with a nicotine compound to destroy aphis. Camellia reticulata is admirable for growing on the back wall of a greenhouse or conservatory.

LILIUM SPECIOSUM.—This is one of the most useful of the autumn-flowering liliums. The bulbs which have been growing slowly in cold frames must be supported with stakes now that they have made sufficient growth. When they have made plenty of roots, they must be given a mild stimulant, increasing it in strength as growth advances. A top-dressing of some rich material will also be of benefit to the plants during the later stages of growth. Batches of retarded liliums, which are approaching their flowering stage, must be given liberal treatment in regard to watering and feeding. If it is desirable to hasten these plants into flower, they may be subjected to plenty of artificial heat, provided the atmosphere is kept moist. If Lilium speciosum is required for flowering at Christmas, the bulbs must be procured and potted towards the end of June.

PILEA MUSCOSA.—This is a most useful little plant for decorative use during the winter months. A good batch of it should be raised from cuttings now for this purpose; in fact, cuttings should be rooted at intervals all through the year, as the plants become shabby if kept too long. The tips of the shoots should be used for cuttings. These should be dibbled rather thickly into 2½in. pots, and placed in the propagating case, where they will quickly root. This plant makes a very effective edging plant for the greenhouse stages. Selaginella Kraussiana is also useful for this purpose, and requires similar cultural treatment to the foregoing.

ASPARAGUS SPRENGERI.—This is most useful for hanging baskets in the conservatory. When established in suitable soil, its growths will reach to a considerable length. It is easily propagated from seeds, which should be sown in pans and placed in heat. Keep the young plants potted on as required until they are large enough to be planted in the baskets. They are also useful when grown in pots.—E. HARRISS, Lockinge Gardens.

HARDY FRUITS.

PEACHES AND NECTARINES.—The disbudding, stopping, and training the young shoots of these will need unremitting attention now that the growth is more rapid, and, if carefully carried out, the winter pruning should be very little indeed. Examine the trees at intervals, and gradually reduce them until only just sufficient shoots are left to take the place of those fruiting this season, which can well be spared in early autumn, always allowing for extension and filling up bare spaces. Retain the best young growths as near the base as possible, and on the upper side of the bearing shoots, and, as soon as they have grown three or four inches in length, tie them in carefully and closely. Use very soft damp raffia for tying, and be careful not to injure the tender bark. Allow all the leaders to extend, and fill up wall space, but those having reached their limit must be stopped. When the fruits are swelling keep the foliage free from green aphis, and encourage an early healthy growth. Remove protecting material as soon as all danger from frost is past, and, if the set of fruit is a plentiful one, remove some of the undersized fruits and those ill-placed, leaving the largest at about four to six inches apart, and thin again later to the required number it is intended to allow the trees to carry.

SWEET CHERRIES. — These should be examined at intervals, and all the young growths required for filling wall space and building-up good fruitful trees should be secured to the walls before they are damaged by wind. Do not train the main branches too thickly. Keep the foliage clean and free from insects. If black-fly puts in an appearance, syringe at once with quassia extract, or some other approved insecticide, so that leaf and branch are thoroughly free and clean before the stoning period. A good watering with lime and soot water, also a few soakings of liquid manure, will greatly assist trees that bear heavy crops of fruits annually.

GOOSEBERRIES.—To obtain large fruits for dessert, the roots of these bushes should be well mulched, and a few applications of liquid manure given on porous land will be very beneficial. If the bushes are very heavily cropped, thin when large enough, using the smaller berries for tarts. Keep the foliage free from red-spider and caterpillars. A slight dusting with hellebore powder will settle caterpillars, but it must be thoroughly syringed off before consuming the berries. Ply the Dutch hoe among the bushes to keep down weeds.

STRAWBERRIES.—These plants are looking very well, and throwing up plenty of strong, healthy flower spikes, which, in some cases, if very large fruits are required, will be better thinned. If not yet done, have the beds strawed down, so that the berries may be kept clean and free from grit, and see that all weeds, etc., are removed before protecting the beds with nets. Plants grown expressly for stock must have all their flower spikes removed, and the beds must be kept clean. These plants usually throw out plenty of strong, healthy runners, which make fine fruiting plants next year.—H. MARKHAM, Wrotham Park Gardens.

THE KITCHEN GARDEN.

MUSHROOMS. — With the advent of warmer weather, some beds may be made in a cool shed, or in a sheltered spot in the open. The most satisfactory results are obtained where a good supply of manure from corn-fed horses is available. It need not consist entirely of droppings, as a little of the short straw may be used. When sufficient material to form a bed has been accumulated, it should be formed into a heap to ferment and sweeten, and a daily turn over will be necessary to avoid excessive fermentation. Let the beds be made piecemeal, and as each layer of material is added, make it firm by treading or beating. Spawning should not take place until the warmth of the bed has declined to about 85 deg.; when spawned, the bed may be covered with soil some two inches deep. Make the surface smooth and firm with the back of a bright spade. If the cakes of spawn have become very dry, it is a good practice to break them up into pieces the size of a chicken's egg, and dip them in warm water before insertion. All beds, whether in the open or in the mushroom house, should be frequently examined, and, if found dry, thoroughly moistened with warm water. To maintain the heat cover the beds with a good thickness of stable litter.

TURNIPS. — Larger plots may now be sown on open quarters, and successional sowings according to the demand. Snowball is an excellent variety; Red Globe is also most reliable, and withstands the effects of drought better than Snowball; those who prefer the yellow-fleshed varieties will find a well-selected form of Golden Ball satisfactory in every way. As a preventive of the ravages of the turnip-flea, dress the rows frequently with soot and wood ashes. Water should be freely applied during dry weather. The proper time to apply the dressings is early morning, when the leaves are damp with dew, failing this, apply after watering, which is best done in the cool of the evening. The chief aim should be the encouragement of growth in the plants, as it is only in the early stages of growth that the flea is so injurious.

CELERY.—The plants which were pricked off some time ago, and have been gradually hardened off, will be ready for transplanting. Well water before removing them, and, if possible, choose a dull day for planting. The soil in the trenches should be made firm, as, if left at all loose, the plants are apt to bolt. After planting, afford a good soaking of water. At no time should the plants lack a sufficiency of moisture. If aphides infest the plants spray with quassia extract.—W. MESSENGER, Woolverstone Park Gardens.

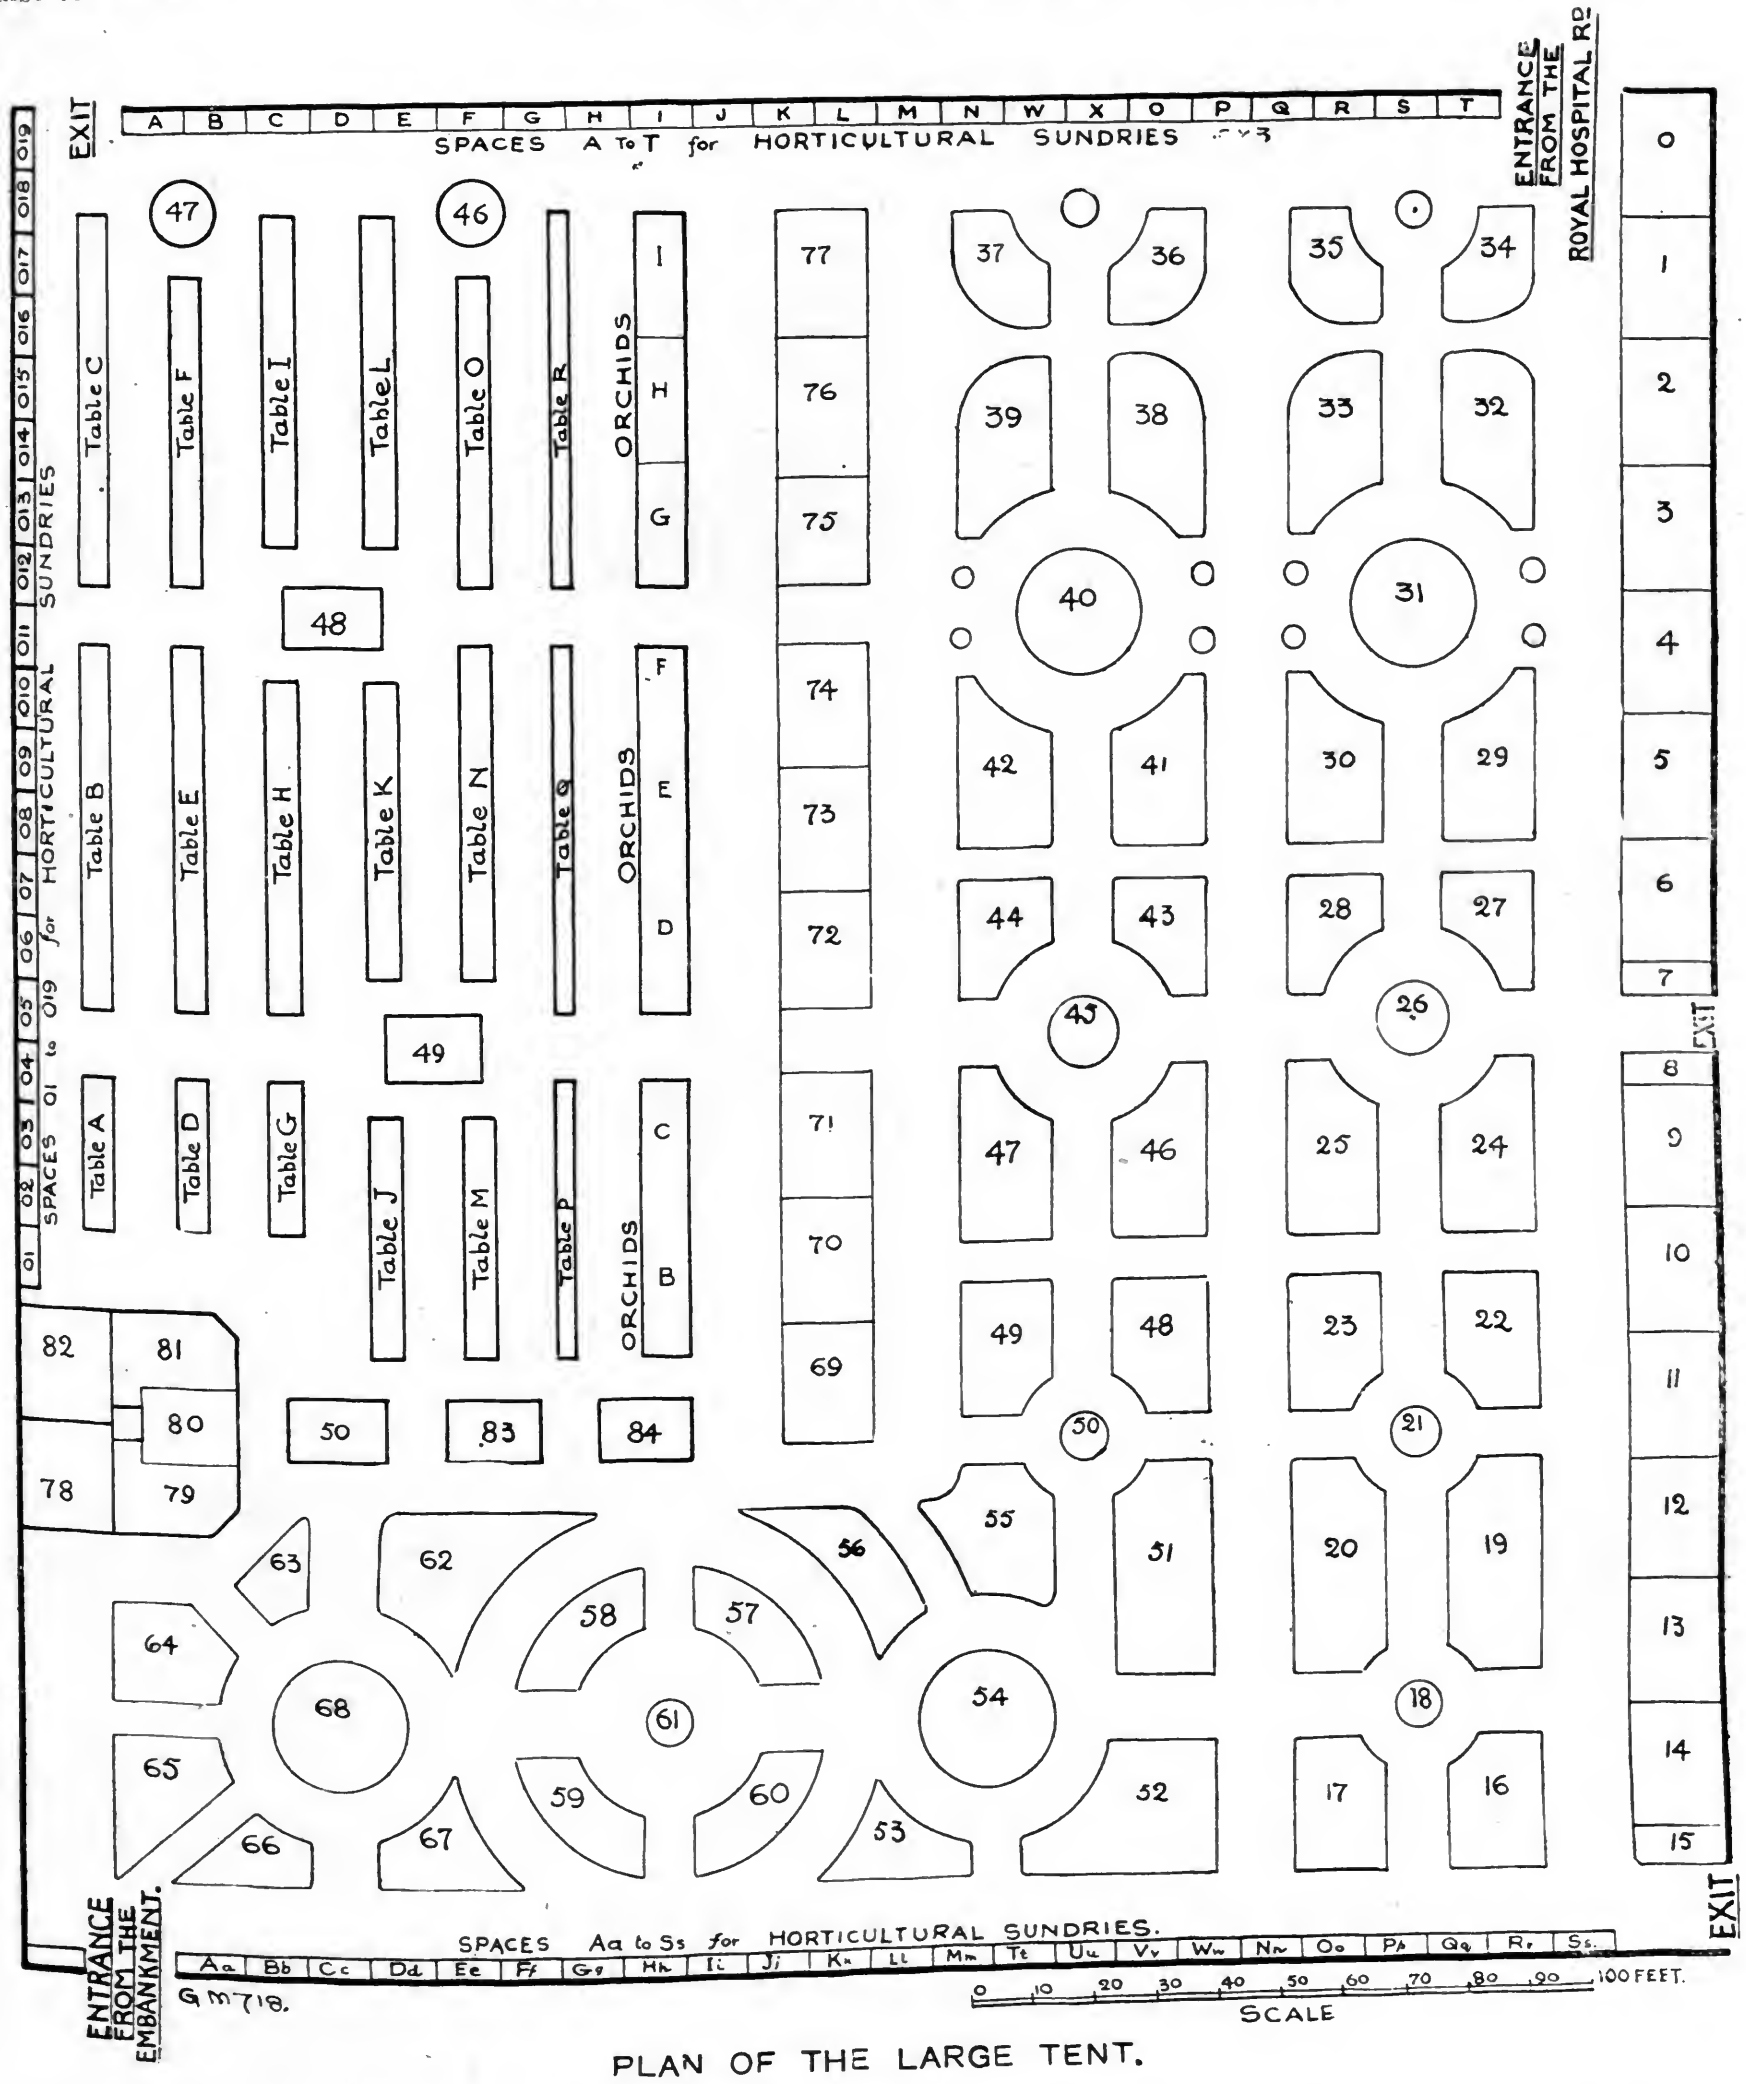
THE GREAT CHELSEA FLOWER SHOW.

The Royal Horticultural Society is fortunate in having for its great spring exhibition a large portion of the site upon which the Royal International Exhibition of 1912 was held, namely, in the grounds of the Royal Hospital, Chelsea. The exhibition has long outgrown the space available at the Inner Temple Gardens, but on the new site, with about three times as much room as previously there will be ample space for the exhibits, and also for visitors.

The great tent, of which we give a plan, is 500ft. long by 275ft. wide, built in six spans, and covers about two acres. In this tent there will be 84 large groups aggregating 21,500 sq. ft., and a further 95 exhibits on tables representing 7,500 sq. ft., will be staged.

In the open air there will be 17 large rock gardens, with paved and formal gardens, large groups of shrubs and garden ornaments. In all there will be 244 exhibitors and 303 exhibits, occupying an aggregate of 73,000 sq. ft., as against 126 exhibitors at the Temple Show of 1911, who filled 25,000 sq. ft.

With the following list of exhibitors and the plan our readers will be able to locate the various exhibits, as the numbers in the list correspond to those on the plan. The outdoor exhibits will be arranged at the Embankment end of the big tent, and by the Avenue.



PLAN OF THE LARGE TENT.

ORCHID TABLES.

Charlesworth and Co.; Colman, Sir Jeremiah, Bart.; Cypher and Sons, James; Davidson, E. H.; Dixon, H.; Hassall and Co.; Holford, Sir George; Low, Stuart, and Co.; McBean, James and A.; Mansell and Hatcher; Sander and Sons; Waters, C. F.

TABLE GROUPS IN LARGE TENT.

Allwood Bros. (R); Allen, A. J. C. (F); Bakers, Lim. (E); Barrie and Brown (M); Barr and Sons (C); Barnes, R. J. (F); Bees, Lim. (F); Bell, B. E. Tomatoes.—Gradually harden off the plants preparatory to planting out towards the latter part of the month. Keep the plants steadily progressing, affording sufficient ventilation to induce sturdy growth. The ground at the foot of the walls against which tomato plants will be planted, should be dug deeply, after dressing it with a fair amount of well-decayed stable manure, lime rubble, and wood ashes. Thoroughly mix the staple with these additions, and make the whole very firm. If wall space is limited the plants may be grown in the open in a sunny position. A few strong stakes should be driven firmly into the ground, and wires stretched thereon; if the wires are not too far apart, upright stakes to each plant will not be required. Put out the plants 18in. apart, and train to a single stem.—W. Messenger, Woolverstone Park Gardens.

MESSRS. WILLIAM BULL AND SON'S SPRING SHOW.

In former years the leading London nurserymen were wont to arrange special exhibitions at their nurseries, and invite their own customers, as well as the general public, to these displays. Such exhibitions were invariably a source of great interest, and no small profit, but since the renaissance of the Royal Horticultural Society's meetings these trade exhibitions have almost ceased. Messrs. William Bull and Sons, however, continue to hold a special annual show in their spacious winter garden at King's Road, Chelsea.

From the entrance door a broad tiled pathway led to the far end of the house, right through the centre. To left and right extended semi-circular pathways in each of which were a pair of circular recesses that accommodated beautiful plants and gave visitors an opportunity of passing each other during an inspection. Fine palms, tree ferns, and tall araucarias, with apidistras, asparagus, and ferns, provided abundant and elegant green setting for the fine rambler roses, such as Tausendschon, Blush Rambler, Hiawatha, Dorothy Perkins, Crimson Rambler, and Mrs. Flight. Banks and corner groups of liliums were an important feature, L. longiflorum, L. auratum, L. speciosum, and L. davuricum being specially prominent and handsome, the first-named being represented by 500 specimens. Here and there groups of blue hydrangeas, of Ceanothus dentatus, and of the yellow and cream-coloured acacias added their quota of beauty. Banks of perpetual carnations and bays of pink and white spiræas and astilbes attracted attention, but the former were evidently the most popular.

But, although all these things were charming in themselves, and disposed in a most delightful manner, they were more or less in the character of stage scenery to provide a suitable background for the orchids and the hippeastrums. Among the former were large numbers of seedling odontoglossums raised by the firm; indeed, the bulk of the orchids on view were home-raised. Lælio-cattleya Aphrodite and L.-c. General Baden Powell were both represented by many dozen plants, and, of course, showed considerable variation in colouring, but all were beautiful. Of these the firm has large batches, and there are plenty yet to bloom. Several plants of a bright orange-yellow hybrid, obtained by crossing Cattleya Schroedreæ with L.-c. Warnhamensis, made a fine contrast with the white, purple, and rose colouring of the two former hybrids. Brasso-cattleya Helen was conspicuous, together with B.-c. Veitchi.

The finest of the odontoglossums was O. crispum Princess Mary, figured in our previous issue, its bold red markings making it very handsome. O. c. Florence, O. c. Marmoria, O. c. Premier, O. ardentissimum, O. armainvilliersense, O. sceptrum, and O. Hallio-crispum, with the purple O. Thompsonianum, were all good, and of even brighter colouring were the odontiodas, O. Chelseaensis, O. Bradshawiæ, O. Charlesworthi, O. Dora, grouped in various parts of the exhibition, the first-named being remarkable for its vigour and freedom of flowering.

Coming to the hippeastrums we may at once say that we have never seen these so fine at the Messrs. Bull's as on this occasion. In form and variety of colouring the strain is a capital one. A few varieties of outstanding merit were Gwendoline, pink; Prima Donna, white and scarlet; Comet, velvety crimson-scarlet, very fine; Mildred, white and pale salmon-scarlet; Queen Alexandra, white, beautifully flushed with pale salmon; Winifred, rose shaded; Queen Mary, white, flushed with rose-red; Conquest, of long shape, old rose, flushed with salmon; Beryl, white, curiously flushed with scarlet; Goliath, flame-red; and Sunbeam, lively vermilion-scarlet, with a white beam down the centre of each segment. For the hippeastrums alone the nursery was, and is still worth a visit.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

It was difficult to imagine May 14 was a Wednesday, because for so many years the R.H.S. meetings have been held on Tuesdays. On this occasion the day was altered to make things easier for exhibitors in connection with the Whitsuntide holidays. There was a fair show, but many people, especially the orchid growers, were holding over for the Chelsea Show. Tulips were the great feature of the meeting, and these were splendidly exhibited, no fewer than fourteen groups being staged. Hardy flowers and alpines were shown freely, and carnations made a good showing. Novelties were good. Messrs. J. Piper and Son, Barnes, exhibited the new yellow Pæony, La Lorraine, referred to at length in our Ghent report, and gained a F.C.C. for it. Other new things are referred to below.

The tulip competition arranged for this day fell through, as the recent storms had damaged the flowers so badly that all the amateurs withdrew their entries.

FLORAL COMMITTEE.

There was a large attendance of the members of this committee, and the number of novelties were rather more numerous than usual.

Sweet peas were most delightfully staged by Messrs. Dobbie and Co., Edinburgh. The flowers were in superb condition, flowers and spikes being alike fine, and the colours beautiful. It was the firm's intention to exhibit sweet peas at Ghent, but lack of sunshine made this impossible. Here they presented some bunches of Brunette, Blue Picotee, with wire edge of blue; Decorator, Thomas Stevenson, Melba, May Campbell, Charles Foster (lovely), Inspector, Marks Tey, and Mrs. Cuthbertson. Some tulips grown at Marks Tey were wonderfully clean, bright, and of grand size and substance, while collarette dahlias, pansies, and violas in pans completed a very fine display.

Capital blooms of Ulrich Brunner, Sunburst, Capt. Hayward, Frau Karl Druschki, Richmond, and Mrs. John Laing roses were sent by Messrs. G. Mount and Sons, Canterbury, and staged by them in some quantity. Mr. Elisha J. Hicks, Twyford, was also an exhibitor of good roses. Roses from Messrs. B. R. Cant and Sons were charming and fragrant, the cut blooms being backed by a selection of rambling varieties; Klondyke, the big white single Silver Moon, and the lovely pink Lady Pirrie commanded attention.

The collection of scented-leaved pelargoniums from Messrs. James Veitch and Sons, Chelsea, proved very interesting, and a source of much pleasure to the ladies; about thirty sorts were staged, each represented by about five neat plants of each kind. Fœocarpus reticulatus, with drooping, fringed white flowers, was beautifully shown by the Chelsea firm. Schizanthus Rosy Gem, with deep rose and maroon-blotched flowers, was shown in fine form by Mr. G. Craddock, gardener to Colonel the Right Hon. Mark Lockwood, Bishop's Hall, Romford. Lilacs, pyruses, rubus, cherries, kerrias, and other flowering shrubs from Messrs. Paul and Son, Cheshunt, proved very interesting.

Some lovely rhododendrons from Miss Mangles, Littleworth, Seale, Surrey, were greatly admired. R. Rose Queen (A.M.) has somewhat drooping flowers of a lovely rose-pink shade, the bloom about three inches long, and scented; R. Wrighti, with pale creamy-yellow bell-shaped flowers, carried on long pedicils in loose clusters (A.M.); R. Rose Mangles, and the red R. cinnabarina. Mr. Phillip Ladds, Swanley, showed Heliotrope The Speaker, a fine grower, with fragrant rich heliotrope flowers; stocks, pelargoniums, petunias, etc., came from the same exhibitor. Embothrium coccineum, rhododendrons, Fritillaria persica, Daphne cneorum, and primulas in variety, were shown among other things by Mr. G. Reuthe, Keston.

Mr. C. Engelmann, Saffron Walden, showed Sunstar, Lady Northcliffe, Carola, and Lady Meyer carnations in fine style. Messrs. Stuart Low and Co., Enfield, had a bold and distinct grouping of carnations, and their flowers of Cinnabar and Baroness de Brienen were very fine. Messrs. W. Wells and Co., Merstham, were other exhibitors of carnations, and they made a speciality of Benora and Northport. A selection of caladiums from new seedlings, such as Bayardo, crimson; Debutante, pink; Commander Peary, pink and red; Lieut. Shackleton, deep red and green; and Argus, of fine shape, pink and rose, with red veins.

Very pretty was Thunbergia Gibsoni, a warm-house climber, with brilliant clear orange flowers and large green and purple bracts, which gained an A.M. for Mr. W. van de Weyer, Smedmore House, Corfe Castle. Mr. J. Elliott, Hassocks, gained an A.M. for Rose Flora Mitten, a large-flowered single, deep blush variety, carrying its flowers in large trusses. Messrs. William Cutbush and Son, Highgate, presented a fine bank of polyantha roses in great variety, as well as hardy flowers, and a selection of carnations, in which the buff Mrs. W. Astor was very conspicuous, and Lady Shrewsbury, a lovely soft pink, with sweet and large flowers, gained the coveted A.M. Messrs. H. B. May and Sons, Edmonton, were represented by heliotropes, salvias, verbenas, and ferns.

Some good varieties of Iris germanica were brought over by Messrs. Goos and Koenemann, Nieder-Wallaf, Germany; Loheugrin, pale blue, and Walhalla, of darker shade, were some of the best. Messrs. Whitelegge and Page, Chislehurst, confined their attention to violas, and put up twenty-one baskets of plants, each basket containing one variety only; this set was much admired.

Among those who set up rock garden displays were Messrs. Bakers, Wolverhampton, whose Incarvillea Delavayi and the large-flowered golden Geum bulgaricum were notable plants.

Messrs. G. and A. Clark, Dover, had some bright hardy flowers; and Mrs. Lloyd Edwards, Llangollen, showed a fine lot of saxifrages in boxes and baskets, together with Anemone alpina grandiflora with flowers three inches across. Mr. H. Hemsley's rock garden contribution was a very interesting one, and contained a mass of the new Myosotis Marie Raphael, with a white stripe down each blue petal.

Mr. W. Miller, Wisbech, displayed violas, etc. Messrs. T. S. Ware, Lim., Feltham, presented a rock garden gay with aubrietias, saxifrages, and hardy orchids. The Wargrave Hardy Plant Farm, The Arcade, Liverpool Street, had a fine lot of hardy primulas, notably P. pulverulenta and the dainty P. involucrata. Messrs. J. Cheal and Sons, Crawley, arranged a rock garden with small shrubs, etc., and they had a beautiful set of Primula japonica carminata. Messrs. Carter Page and Co., London Wall, were represented by violas, annuals, and early dahlias. Miss Willmott, V.M.H. (gardener, Mr. C. Fielder, V.M.H.), Warley Place, Great Warley, showed the glowing tritoma Orange King.

ORCHID COMMITTEE.

The contributions to the meeting of this committee were comparatively few in number, but of much interest.

Mr. Macdonald, gardener to Sir George H. Kenrick, Whetstone, Birmingham, secured a Silver Flora Medal and Cultural Commendation for thirteen fine plants of Dendrobium Dalhousieanum, all carrying long, drooping panicles of buff, maroon-blotched flowers; these plants were all raised from one specimen secured a few years ago. A very large specimen of D. Dalhousieanum exhibited by Mr. Salter, gardener to Lord Lawrence, Chetwode Manor, Bucks, stood six feet high clear of the pot, and carried a dozen grand spikes. A Cultural Commendation was worthily awarded.

From the Orchid Nursery Company, Gateacre, came a small group of Lælio-cattleya Cowani, and other lælio-cattleya hybrids. A curious Lissochilus with yellow and green flowers, evidently a free grower, with spikes 3ft. to 4ft. high, was shown by Mr. W. van de Weyer, Smedmore House, Corfe Castle, Dorset.

From the Burford Lodge collection Mr. White, grower to Sir Trevor Lawrence, Bart., brought up a fine example of Brasso-cattleya Nivalis, with over thirty white flowers; Lælio-cattleya Fascinator-Mossiæ, with lovely purple lip (A.M.); L.-c. Fascinator, with six splendid blooms; and Odontoglossum crispum. Messrs. J. and A. McBean, Cooksbridge, staged Odontoglossum Phœbe splendens (A.M.), with flowers fully four inches across, the segments being much broader than in the usual forms of this graceful odontoglossum. Dendrobium Falconeri, shown by W. R. Lee, Esq., Plumpton Hall, Heywood, was especially fine, nearly a yard high, smothered in bloom, and in a 54-sized pot; from the same exhibitor came Odontoglossum Parlova, with deep maroon-purple flowers.

NARCISSUS AND TULIP COMMITTEE.

The displays of tulips submitted to this committee were numerous and of great excellence.

A particularly fine exhibit of Darwin and May-flowering tulips was arranged in very bold style by Messrs. Sutton and Sons, Reading, on a high four-tiered staging with a background of acers and bamboos. The flowers were very large, and the varieties, set up in groups of four bunches each, were most imposing. Particularly striking were the representations of Bacchus, Sunrise, Scarlet Emperor, Orange King, Clara Butt, Fairy Queen, Psyche, La Tristesse, Mrs. Stanley, Pride of Haarlem, Inglescombe Pink, and Philippe de Commines and Black Chief, two of the black tulips. Messrs. R. H. Bath, Lim., Wisbech, set up a fine lot of Cambridge-grown tulips, all Darwin and May-flowering sorts, tall, stately, and brilliant. There were about a hundred varieties, each represented by a good bunch of from a dozen to a score of flowers. A few varieties of outstanding merit were Salmonea, Mrs. Moon, Fairy Queen, Orange King, Suzon, Bleu Aimable, The Fawn, and Golden Goblet.

Tulips, almost entirely Darwin varieties, were capitally displayed in tall glass vases by Messrs. Jas. Carter and Co., Raynes Park. There were about fifty large bunches, and notable among the varieties were Mrs. Cleveland, Loveliness, Clara Butt, Mons. S. Mottet, the branching stemmed white tulip; Mrs. Moon, Gretchen, The Fawn, the lovely Inglescombe Pink, and the bold rose-pink Antony Roozen. Some splendid tulips from Messrs. Hogg and Robertson, Dublin, showed that the Irish climate had been more kind of late than our own, for the flowers were wonderfully clean; Biscuit, Millet, Pride of Haarlem, Fairy Queen, Rev. W. Ewbank, Inglescombe Pink, and Mrs. Moon were grand, and a vase of Iris lupina was as much admired as the tulips.

Mr. Christopher Bourne, Simpson, Bletchley, put up a score or so of vases of clean tulips that included such good yellow sorts as Bouton d'Or, Solfaterre, Mrs. Keighley, and Mrs. Moon. Messrs. R. Wallace and Co. submitted tulips associated with Japanese maples, and a selection of irises, the latter including a series of the regelia hybrids, with I. violacea, etc. Among the tulips Beauty of Bath, Chameleon, Jaune d'Œuf, Inglescombe Scarlet, and Grenadier were conspicuous. Messrs. Jas. Veitch and Son, Chelsea, presented Darwin tulips, and also a good selection of the gorgeous and interesting Parrot varieties.

Messrs. Barr and Sons, Covent Garden, filled a large space with a famous collection of tulips, a hundred and eighty varieties

being staged at the end of the hall; Inglescombe Yellow, Inglescombe Pink, W. T. Fish, Bouton d'Or, Louis XIV., King Harold, Salmon Prince. Velvet Gem, John Ruskin, Doris, and Flamingo were sorts we made special note of. Messrs. R. and G. Cuthbert, Southgate, set up well-grown tulips loosely in large vases, and staged a very representative collection.

Some of the very finest of tulips were those brought from St. Asaph by Mr. W. A. Watts. The blooms were very fine in size, form, and colour, but the varieties were somewhat limited, the finest being Clara Butt, Picotee, Suzon, King Harold, Pride of Haarlem, Baronne de la Tonnaye, The Fawn, Gesneriana lutea, and Inglescombe Pink. Other exhibitors of tulips were Miss Dixon, Edenbridge; Messrs. Fells and Son, Hitchin; and the Wargrave Hardy Plant Farm, The Arcade, Liverpool Street.

ROCK GARDEN COMPETITION.

Three competitors entered for the Clarence Elliott Cup offered for an exhibit of rock garden plants, and these were Sir Everard Hambro, Hayes Place, Hayes; Mr. E. J. Arbib, Martens Grove, Crayford; and Captain Treherne, Muirburn, Strathaven. Sir E. Hambro (gardener, Mr. Granfield) secured the cup for an arrangement in which Lewisia Howelli, Silene Hookeri, Saxifraga cochlearis, S. argentea, S. calyciflora, Asperula suberosa athoa, Haberlea virginalis, Jankea Heldreichi, Oxalis cuneaphyllo rosea, and Helichrysum bellidioides were the leading features.

CERTIFICATES AND AWARDS.

First Class Certificate.—To Pæony La Lorraine, from Messrs. J. Piper and Son, Barnes and Bayswater.

Award of Merit.—To Brasso-laelio-cattleya Veitchi, The Dell var., from Baron Bruno Schröder (gardener, Mr. Shill), The Dell, Egham; to Odontoglossum Phœbe splendens, from Messrs. J. and A. McBean, Cooksbridge; to Lælia-cattleya Fascinator Mossiæ, from Sir Trevor Lawrence, Bart. (grower, Mr. W. H. White), Burford Lodge, Dorking; to Heliotrope The Speaker, from Mr. Phillip Ladds, Swanley Junction; to Carnation Lady Shrewsbury, from Messrs. William Cutbush and Son, Highgate; to Rose Flora Mitten, from Mr. J. Elliott, Hassocks; to Aster Purdomi, from Messrs. James Veitch and Sons, Chelsea; to Thunbergia Gibsoni, from W. van de Weyer, Esq., Corfe Castle; to Rhododendron Rose Queen and R. Wrighti, from Miss Mangles, Littleworth, Seale, Surrey; and to Tulip Massanet, from Messrs. R. H. Bath, Lim., Wisbech.

MEDALS.

Silver-gilt Flora.—To Messrs. Dobbie and Co., Edinburgh, for sweet peas, etc.; to Messrs. G. Mount and Sons, Canterbury, for roses; to Messrs. Sutton and Sons, Reading, for tulips; to Messrs. J. Carter and Co., Raynes Park, for tulips; to Messrs. Hogg and Robertson, Dublin, for tulips.

Silver-gilt Banksian.—To Messrs. William Cutbush and Son, Highgate, for roses and carnations; to Messrs. Barr and Sons, Covent Garden, for tulips; to Messrs. R. H. Bath, Lim., Wisbech, for tulips, and to Mr. W. A. Watts, St. Asaph, for tulips.

Silver Flora.—To Sir G. Kenrick (gardener, Mr. Macdonald), Whetstone, Birmingham, for dendrobiums; to Mrs. Lloyd Edwards, Llangollen, for saxifrages; to Mr. G. Reuthe, Keston for rare shrubs, etc.; to Messrs. James Veitch and Sons, Chelsea, for pelargoniums, etc.; to Messrs. R. Wallace and Co., Colchester, for tulips; to Messrs. R. and G. Cuthbert, Southgate, for tulips.

Silver Banksian.—To Messrs. Dobbie and Co., Edinburgh, for tulips; to Messrs. J. Veitch and Sons, Chelsea, for tulips; to Mr. C. Bourne, Bletchley, for tulips; to Messrs. B. Cant and Sons, Colchester, for roses; to Mr. C. Engelmann, Saffron Walden, for carnations; to Mr. A. Hemsley, Crawley, for alpines, etc.; to Mr. P. Ladds, Swanley Junction, for greenhouse flowering plants; to Messrs. Stuart Low and Co., Enfield, for carnations; to Messrs. H. B. May and Sons, Edmonton, for greenhouse plants; to Messrs. Paul and Son, Cheshunt, for flowering shrubs; and to Mr. Charles Turner, Slough, for caladiums.

Bronze Flora.—To Messrs. J. Cheal and Sons, Crawley, for rock garden; to Messrs. Fells and Son, Hitchin, for hardy flowers; to Colonel M. Lockwood, M.P., Romford, for schizanthuses; to Messrs. Reamsbottom and Co., Geashill, Ireland, for anemones; to Wargrave Hardy Plant Farm, Arcade, Liverpool Street, E.C., for alpines; to Messrs. Whitelegg and Page, Chislehurst, for violas.

Bronze Banksian. — To Messrs. Carter Page and Co., London Wall, for violas and annuals.

Scottish Horticultural Association.

The monthly meeting of this association was held at 5, St. Andrew Square, Edinburgh, on the 6th inst. Mr. King, the president, was in the chair, and there was an attendance of eighty-five members.

The evening was an open one, and questions relating to the production of young potatoes at Christmas from tubers which had not been allowed to sprout (of which authenticated cases were given); the production of blue colour in the flowers of hydrangea; the question: "What is a hardy exotic plant, as defined in Flower Show schedules"; and questions relating to the cultivation of the soil, fruit growing, and other matters were discussed.

The exhibits were: New aubrietias, exhibited by Mr. F. Baillie, Liberton; calceolarias, sweet peas, and collarette dahlias, exhibited by Messrs. Dobbie and Co., Edinburgh; new auriculas, exhibited by Mr. John Fraser, The Old Manse, Inverkeithing; Deutzia crenata magnifica, and D. crenata latifolia, exhibited by Mr. A. Porter, Davidsons Mains; and vegetables and new strawberry, Liberal, exhibited by Mr. James Scarlett, Sweethope. Messrs. Dobbie and Co., Mr. Porter, and Mr. Scarlett were awarded cultural certificates for their exhibits.

At the meeting on June 3, Mr. R. K. Brown, Dunnikier Gardens, Kirkcaldy, will read a paper on "Soil Knowledge."

The Alpha No. 3 obtained First Award for Hand Sprayer at the R.H.S. Trials, Wisley, April 23rd, 1913.

The finest Garden Sprayer in the World.

As used in Windsor Castle Gardens.

It is proof of the superiority of the Alpha that it has the approval of the Royal Gardeners, and is used throughout the gardens of Windsor Castle. It also bears the hall mark of quality conveyed in the expressed satisfaction of the Royal Horticultural Society, who regard it as being one of the simplest and best machines they have ever tested. During last year many thousands of these handy little machines were sold for many different purposes, to which they admirably suit, but by far the greater quantity were sold into the gardens of this and other countries, where they are giving the most efficient service.

ALPHA SPRAYER,

No. 3, 3-Quarts Capacity, Price 17/6

is an important item in every well-equipped garden. It is always ready to be charged for any spraying purpose, with thick or thin fluid, either of which it distributes with force and fineness. The Alpha is the simplest possible machine. It has not an attached pump, either internal or external. The air which provides the distributive energy is compressed in the machine by means of an ordinary cycle foot-pump, attached to and detached from the machine exactly as to a cycle tyre. The all-steel body is protected internally against the corrosive action of chemicals by a lining of lead, further reinforced by a coating of bitumen mastic.

YOUR SEEDSMAN

either has Alphas in stock to supply your immediate requirements, or can get an Alpha for you in 24 hours, therefore insist on the Alpha and refuse imitations.

AWARDED 18 GOLD AND SILVER MEDALS.

Send for the Alpha List if you want a larger machine. Alphas are made in varying capacities up to 40 gallons and more, and also ask for the new Carmona Plant Food Book on plant feeding, and Set of Art Post Cards.

ORCHIDS: THEIR POPULARITY AND CULTURE.

The following is the text of a lecture delivered before the Bath Gardeners' Society recently by Mr. H. Alexander, orchid grower to Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury, Gloucester.

The cultivation of orchids, commencing over a century and a-half ago, has always been an extremely attractive subject, for among these plants we have the most exquisitely curious and beautiful of all Nature's productions. The extraordinarily formed flowers are rich in every shade and blending of colour; some of them possess a fantastic appearance, and often emit the most refreshing and delicate odour.

Orchid growing was at one time looked upon as exclusively the privilege of the few, and as a craze. This, like many of the old ideas associated with the cultivation of these interesting plants, was, as seen in the light of present-day knowledge, very extraordinary. Formerly, there were several reasons which caused many who admired them to hesitate before undertaking their cultivation. The high price which nearly all the showy kinds commanded was in itself a serious matter, to say nothing about the uncertainty that existed as to their growing, after large sums had been spent in procuring them. In the early days, orchids, as soon as received, were placed in houses where a hot, steamy atmosphere, without ventilation, was maintained at all times, a method adopted to imitate the damp, close jungle in which all tropical orchids were then supposed to have their home.

It was towards the middle of the nineteenth century that a change of system in growing orchids under artificial conditions was brought about by Joseph Cooper and Donald Beaton, two of the ablest and most scientific gardeners in this country in those days. These cultivators, grasping the truth in the direction that more attention should be paid than hitherto to the climatic conditions under which orchids grow at the various altitudes in the tropics, adapted their cultural treatment accordingly by commencing to keep a more reasonable temperature, and admitting fresh air into the houses. Somewhere about the same time Mr. Paxton, afterwards Sir Joseph Paxton, adopted a similar treatment and an improved method of potting, with special regard to efficient drainage and extra attention to root development. These were the chief deviations from the established practice, and in them we see the approach to the cultural routine of the present day. Another change that had an enormous influence on the cultivation of all plants under glass, and contributed in no small degree to the improvement and extension of the cultivation of orchids, was the heating of glass-houses by means of the hot-water system. Then followed the modern plant house with the improved methods of ventilation and means for the promotion of humidity.

How to popularise orchid growing has for many years past occupied the minds of those who have been associated with these plants. Neverthless, one could scarcely expect much advance in this direction until a fair idea of their modest needs became more widespread than hitherto. For upwards of a quarter of a century there has been much evidence forthcoming as to the right and wrong methods of culture, and I venture to say there is no branch of modern horticulture that exhibits such wonderful progress as the cultivation of orchids. Their popularity to-day is greater than any other class of plants that require to be grown under glass, and the ranks of their admirers are ever increasing. Who will say that their popularisation is not still in its very infancy? The Royal Horticultural Society, without doubt the leading society of its kind in the world, has recently erected at Wisley a very large and elaborate structure for the cultivation of orchids. This fact alone is of sufficient evidence to one and all of the popularity of orchids, and of the importance that every gardener must in these days have a good knowledge of their cultivation. All students at Wisley thus have every facility for acquiring proficiency in the art. The good and necessary example set by the society should encourage the formation of collections, large or small, and all gardeners should study the nature of these plants in order that they may be fully prepared in case of necessity.

It is by no means necessary to have a complete range of greenhouses before embarking on orchid culture. Anyone wishing to add grace to the ordinary run of greenhouse plants will find one or two houses amply sufficient to successfully grow a very large and representative collection of beautiful orchids. In forming a small collection, I always advise keeping to the best known and easiest grown kinds, selecting them to suit the house they are to be grown in. For example, it is useless to try to grow cattleyas and odontoglossums under similar conditions. Both are of fairly easy culture, and essentially orchids for the small collector if arranged in a suitable house and temperature. If only one house is devoted to orchids, I would always advise keeping this at an intermediate temperature, that is, a minimum winter temperature of 50 to 55 degrees by night and 55 to 60 degrees by day, these figures to rise in summer 5 degrees by artificial heat, and up to 80 degrees when the sun is bright. In this temperature it is possible to grow a great variety of orchids, including some of the showiest and most beautiful kinds in existence.

(To be continued.)

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

DISEASED LEAVES OF CLERODENDRON FALLAX.—J. M. S., Chew Magna: I shall be glad if you will explain the dirty patches on the leaves of Clerodendron fallax I send herewith. I had the same trouble last year, and have used strong insecticides without effect.—The patches are due to the presence of one of the fungi, and the damp, moist surroundings in which the plants are growing facilitate the spread of the disease. Spray the plants occasionally with a weak solution of sulphide of potassium, and at intervals dust affected parts with flowers of sulphur.

REPOTTING A CACTUS.—S. R., Aylesbury: Some time ago you were kind enough to reply to me concerning a root-bound cactus. I now send a piece of growth. The flowers are white, and the plant is about to flower. Can I divide and repot specimen safely?—The plant is a phyllocactus, but what species or variety we cannot state. After the plant has flowered it may be divided, but the work should be done with great care, and it is desirable that every portion carries a supply of roots. Use comparatively small pots, as phyllocacti dislike overpotting; well drain the pots, and use a

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

compost of fibrous loam, some old decayed manure, and some crushed old mortar or lime rubble. A handful of wood ashes may be added with advantage. Pot firmly, and keep the plants shaded and in a closer, moister position than usual until the roots have taken a good hold upon the new soil, when more light and more ventilation must be given until they are exposed to full light. All cacti love plenty of bright light and sunshine.

"KEW BULLETIN."—C. D. J., Nottingham: Kindly tell me where I can obtain the "Kew Bulletin"; I believe this publication frequently deals with Colonial matters, therefore I should like to obtain it.—The "Kew Bulletin" can be obtained through any newsagent, or from Wyman and Sons, Fetter Lane, London, E.C.

NECTARINES DROPPING. — H. R., Leatherhead: Having been a reader of The Gardeners' Magazine for about twenty-five years, I venture to ask your opinion concerning the dropping of nectarine fruits, examples of which I enclose. I have had charge of the trees for fourteen years, and have always had excellent crops of quite exhibition-sized fruits. This season the trees have been treated in precisely the same manner as hitherto. The house is a hip-span, facing south, with inside border. The latter was mulched in the winter with cow manure. The trees started to bloom before heat was turned on, and the temperatures have been kept even, beginning with 40 degrees, and lately 55 degrees on mild nights with a corresponding rise by day, with air top and bottom; so I feel sure there has been no check. Last year the trees carried heavy crops, and I have never before had any difficulty during the stoning period. Last season, when the fruits on some of the trees were ripe, my employers were away, and so I shaded the house to keep the fruits until they returned. Perhaps this, and the sunless autumn weather, may have been the cause of our present trouble. Any help you can afford will be greatly appreciated. I may add that a little lime is sprinkled on the border occasionally previous to watering with rain water.—There is nothing whatever in the full-sized leaves, the fruits and the growths sent, to suggest the cause of the loss of crop by the fruits dropping. Stoning is often a troublesome period, but as there has been no trouble in this direction previously, it is difficult to account for it now. We can only suggest that the shading last year, coupled with the cool, sunless autumn, kept the wood from ripening properly; a heavy crop kept on the trees as long as possible would also retard ripening of the wood. Give the borders a good dressing of lime or old plaster rubbish, and proceed with your usual excellent methods to secure well-ripened growth for the sext season's crop; the circumstances have been unusual this year.

BLISTERED VINE LEAVES.—G. R., Cray: I am enclosing leaves of Alicante vine which show some blisters. Kindly tell me the cause and remedy. Ours is a small span-roofed vinery with four pairs of vines, representing four varieties. The fellow cane to the one with blistered leaves shows no sign of any trouble. The border is an inside one, and the vines have been planted about six years.—The weather has had a great deal to do with the blistering. Bursts of sunshine have played upon the leaves while they were very sappy and soft. The use of a little more fire heat during dull weather, accompanied by sufficient ventilation to provide a fresh, brisk atmosphere, will work wonders. Probably the vine affected was overcropped last year, or its position may be such that it receives more moisture than the others; in any case, it is not in such good health as the rest of the vines, and this is due to some local cause. Remove the badly affected leaves, and dust any that show blistering with flowers of sulphur, so that mildew or mould may not develop. The real cause of the mischief can only be ascertained by close observation.

PRIMROSES.—C. P., Linwood: The primrose of which you send us flowers is very fine, but it does not appear to be sufficiently distinct from some that are already in cultivation to justify it receiving a distinctive name. It is not, however, possible to determine the merits of primroses or other flowers from two or three blooms, and we suggest that you submit a dozen or so of well-grown plants to the Royal Horticultural Society's Floral Committee in the spring of 1914. It should certainly be taken care of.

COLLARETTE DAHLIAS.—M. W., Basingstoke: I propose to plant some of the collarette dahlias this season, and should be glad if you will suggest a good dozen varieties, and where I can obtain them.—You can obtain collarette dahlias from any of the nurserymen who advertise in our columns. In this new group considerable difficulties arise when a selection is desired, as so much depends upon personal taste. However, the following are all good: Betty, heliotrope, white collar; Corbeille de Feu, bright orange-terra cotta, yellow collar; Diadem, rosy pink, white collar; Diamant, deep rose, pale rose collar; Gallia, crimson, with creamy edge and collar; Grand Papa Charmet, rich crimson, creamy collar; Henri Farman, yellow, shaded red, creamy collar; Leitstern, dark crimson, white collar; Mdme. Poirier, blush-purple, white collar; Maurice Rivoire, deep crimson, white collar, a fine garden dahlia; Souv. de Chabane, vivid yellow, crimson shaded, with yellow, white-tipped collar; and Souv. de Bernardeau, old rose.

NAMES OF PLANTS.

F. E. S., Bletchley.—1, Primula involucrata; 2, Saxifraga cæspitosa; 3, Erysimum rupestris.

A. A., Exeter.—1, Cheiranthus Marshalli; 2, Polypodium Dryopteris; 3, Thalictrum flavum; 4, Calceolaria Clibrani; 5, the double form of Saxifraga granulata.

S. P. R., Aylesbury.—1, Arenaria montana; the viola looks very much like the old Cleveland Purple, but is probably a slight colour reversion from a named sort, or a seedling.

E. T., Beaumaris.—1, Desfontainea spinosa; 2, Cassinea fulvida (or Diplopappus chrysophyllus); 3, probably Olearia stellulata, send again in autumn; 4, Berberis Wallichiana; 5, a form of Arbutus hybrida; 6, Pittosporum Tobira.

P. B., Rugby.—1, Acalypha Macafeeana; 2, send when in flower; 3, Mahonia aquifolia; 4, Euonymus radicans variegata; 5, a form of Caragana arborescens; 6, Tiarella cordifolia; 7, a Sedum, probably S. lydium, send when in flower.

Spraying.

One of England's leading Fruit Growers says: "I consider the 'Four Oaks' Spraying Machine, **'Battle'** Pattern, to be **the only** practical machine on the market."

FORTHCOMING ENGAGEMENTS

NEXT WEEK.

TUESDAY, May 20.—Royal Horticultural Society's Great Exhibition in the Royal Hospital Gardens, Chelsea; opens at 12 noon.

WEDNESDAY, May 21.—Chelsea Flower Show, continued; admission from 7 a.m. to 8 p.m.

National Tulip Society's Exhibition in connection with the Chelsea Show.

Devon County Show, at Barnstaple; three days.

Royal Meteorological Society's Meeting.

Kew Guild Annual Dinner at the Holborn Restaurant at 6.45 p.m.; dinner at 7.30 p.m., Mr. William Goldring in the chair.

Perpetual Carnation Society: Dinner at the Holborn Restaurant.

THURSDAY, May 22.—Chelsea Flower Show, concluding day; admission from 7 a.m. to 6 p.m.

SATURDAY, May 24.—Linnean Society's Anniversary Meeting.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Horticulture at Chelsea.

There is no occasion for surprise that the great horticultural exhibition, which during the past week brought in their tens of thousands gardening experts and garden lovers to Chelsea, should have created interest of a quite exceptional character. Such is the reputation of the Royal Horticultural Society that no doubt arises in the public mind as to whether an exhibition held under its auspices will be successful. But the Chelsea show represented a quite distinct advance on the part of the society, and it came into comparison not only with the many exhibitions that have been held for a long series of years in the gardens of the Inner Temple, but with the great international gathering at Chelsea last year. This comparison it has borne in a manner that has justified the anticipations of the most sanguine, and the exhibition may without hesitation be recorded as one of the most complete of the many successes the society has achieved in the course of its many-sided activities during the past quarter of a century. As compared with the Temple shows, extensive, interesting, and attractive as they unquestionably were, the Chelsea show evinced such an immense improvement in every particular upon them as to give rise to a feeling of unbounded satisfaction to the visitors, whether Fellows or otherwise. The area of the exhibition was fully three times as large as the most extensive of the shows within the boundaries of the City, a point of some importance; but still more important is the fact that visitors could move about freely, and with some degree of comfort. Great as was the additional space provided both for exhibitors and visitors, it was by no means in excess of requirements, for exhibitors were heard complaining of their failure to obtain all the room they had applied for, and the huge tent became decidedly crowded at certain hours, even on the opening day, when the charge for admission was comparatively high. To moderate crowding no serious objection could well be taken, and it is a distinct asset to a society, inasmuch as comparatively few members of the general public care for thinly-peopled exhibitions, whether horticultural or otherwise. Notwithstanding this fact, it would probably be well on the occasion of future exhibitions to increase the tent by at least one span, and add two or three feet to the width of the gangways. Comparisons were very freely instituted by the many visitors between the exhibition of the past week and the international gathering of last year, and by no means to the disadvantage of the first of the two. It was not on so large a scale, as indicated by the fact that the whole of the exhibits were arranged in the Royal Hospital grounds under canvas, or in the open, and that the area of the tent was less. The exhibition in the big tent was, however, larger in proportion to the area of canvas than was that of last year, the additional accommodation being obtained by the reduction of the space allotted the visitors, which, as already mentioned, appeared to have been carried a trifle too far, especially on the western side of the tent, where the tables are arranged in parallel rows. Of the various classes of plants and flowers that were shown we have, with but trifling exceptions, nothing but praise. All that are available for exhibition at this time of year were shown in a condition at least equal to that of similar kinds contributed to last year's exhibition, and they were, as a whole, arranged with much greater taste. The improvement in the latter respect was evidenced both in the general scheme and in individual grouping, and we are in accord with the consensus of opinion as to the greater attractiveness of the exhibition. As so well shown in the comprehensive and otherwise admirable report that appears in another part of the present issue, one of the most beautiful and interesting of the many features was that formed by the wondrous display of orchids. In the method of presenting orchids to public notice our cultivators are far in advance of those who give their attention to these plants in other parts of the world. Much as we should like to see some reduction in the height of arrangements of orchids, we do not suggest that exhibitors should have restrictions placed upon the exercise of their taste. Roses were exhibited in much larger numbers than usual, and the numerous groups formed a series of object-lessons of much value in the use of the rambling roses, in their diversity of training, for decorative purposes. It might also have been seen how much better is the effect produced when standard and pyramidal specimens of both rambling and climbing polyantha roses are associated with an undergrowth of the hybrid teas, than when the carpeting is formed with dwarf varieties having small flowers. As in the case of orchids, nowhere are roses so tastefully shown as in this country, and the same is true also of carnations, which constituted a delightful feature, in which skilful development of the individual blooms and tasteful arrangement were happily combined. Hardy trees and shrubs were somewhat unequal, a fact that is not surprising considering the difficulty that is experienced at this season of the year in exhibiting any considerable number of those remarkable for the beauty of their flowers at the same time. Mollis azaleas and a considerable number of hardy rhododendrons may now be had in perfection, and the several bold groups produced a brilliant effect. Clematis were

MR. H. NAYLOR.

also finely shown, but in some cases miscellaneous flowering shrubs were not specially attractive, owing in part to the plants not having attained to a very high degree of development, and in part to their being too crowded. It was rather too early for the occupants of the herbaceous border to be shown on an extensive scale, but several good collections were exhibited, and there was a surpassingly beautiful display of alpine flowers in the numerous rock gardens that formed so delightful a feature on the southern side of the grounds. Considering the heavy outlay involved in the formation of such gardens, the enterprise of exhibitors is deserving of much praise; as, indeed, is that of the majority of those who contributed so liberally of the products of their skill. If we may add a further word or two of criticism, it would be in reference to the poor approach to the exhibition from the Embankment gate. Surely not a few exhibitors would have been willing to incur considerable expense to do the most of the beautifying of such approach after the bulk of the cartage is finished, on the eve of the show. Then too, at the hospital end of the tent, packing-cases were very much in evidence, and detracted from that finish we expect at a great exhibition of this kind. Another year it may be possible to arrange the horticultural sundries together apart from the plants and flowers. We are glad to be able to record that fine if not brilliant weather was experienced during the first two days. Queen Alexandra paid a visit early on Tuesday, and expressed great pleasure in all she saw, and ere the day had run its course the society had set up a new record of attendance and takings for a "first day."

Mr. H. Naylor, head gardener to Lady Battersea at The Pleasaunce, Overstrand, Cromer, is still a young man, but he has crowded just about as much horticultural experience as possible into his life. He has charge of one of the most delightful, and, at the same time, most unique of gardens, one designed very largely by the late Lord Battersea, so close to the sea that many people thought the position an impossible one for a good garden. By means of clever shelter, planting conditions have been provided which, added to skilful culture, have made The Pleasaunce one of the most successful gardens in the country. Mr. Naylor commenced his horticultural career in his uncle's nursery at Harrow. From Harrow to Tring Park was an easy migration; here he spent four years under the late Mr. Hill, and then took service at Effingham Hill House, near Dorking, under Mr. A. Alderman. After eighteen months at Effingham and three years at Aldenham House Gardens, under Mr. E. Beckett, he became foreman to Mr. Tidy at Stanmore Hall, Middlesex, where he stayed three years before taking his first appointment as head gardener to the late Mrs. Macdonald, at Preston Manor, Brighton. The Harrow district seems to have had a peculiar attraction for Mr. Naylor, for, after two years at Brighton, he took charge at Piggott Manor, Elstree; the late J. M. Hughes, Esq., leased Piggott Manor, and subsequently purchased Harrow Weald Park, and to this larger charge Mr. Naylor was transferred after three years at Piggott Manor. Four years at Harrow Weald Park concluded his preparation for The Pleasaunce, where he has done such excellent work during his six years of office.

Odontoglossum crispum Princess Mary.—On Thursday, the 15th inst., Messrs. William Bull and Sons had the honour of attending by Royal command at Buckingham Palace for the purpose of showing Princess Mary the beautiful new odontoglossum dedicated to her Royal Highness, which we illustrated in our issue of the 10th inst.

Mothers' Day Celebration.—For several years past Mothers' Day has been celebrated in the United States and Canada, usually on the second Sunday in May, when everyone is expected to write or go to see his or her mother, and wear a coloured flower, while, if the mother has passed away, a white flower is worn, and flowers are laid upon the grave. An effort is being made to institute such a celebration in our own country, and it deserves the support of everyone, and particularly of florists and lovers of and workers among flowers. The Y.M.C.A. is moving in the matter, and held a celebration at the headquarters, Tottenham Court Road, on Sunday last, but the movement is not confined to any one sect or body, though in its initial stages it is being confined to men. What do our readers think of the Mothers' Day idea?

Royal Gardens at Athens.—The King of Greece is having new gardens formed, and the old gardens remodelled in connection with the Royal residences at Athens, and the work of designing the former and the remodelling the latter has been entrusted to Mr. A. Prentice Mawson, the son of Mr. T. H. Mawson, the well-known garden architect.

Protection from Fire at Truro Show.—The fire protection arrangements at the Bath and West of England show, which will be held at Truro during the coming week have been entrusted to Messrs. Merryweather. An equipment of motor and horse fire engines will be installed at their fire station in the exhibition ground, and fire-main piping will be laid down with hydrants fixed at various points. The fire protection equipment will be in charge of a detachment of the Merryweather fire brigade. The firm will exhibit several new steam and petrol-driven pumps for water supply, fruit tree spraying, etc.

Cambridge Readership in Forestry.—Mr. William Dawson, lecturer in forestry in the University of Aberdeen, has been offered by the General Board of Cambridge University the appointment of Reader in Forestry at Cambridge University, in succession to Mr. A. Henry—the position being that of head of the Forestry Department of the University. Mr. Dawson, who is a native of the city of Aberdeen, has had a good record. He holds the M.A. and B.Sc. degress of Aberdeen University, and is considered one of the leading experts in this country on the subject of forestry. Under his skilful supervision the Forestry Department of Aberdeen University has made remarkable progress during the six years he has held the lectureship. As a student at Aberdeen University Mr. Dawson met with much success, gaining prizes in botany, zoology, economics, and agriculture. He was also elected to a Carnegie Scholarship, and subsequently to a Fellowship for study abroad. He went to Germany and Austria, and devoted himself to the study of forestry in the Forestry Academy at Tharandt, Saxony, and also at Munich, studying specially under Professors Neger, Neumeister, and Mayr. On his return home he was appointed to his present post, that of lecturer in forestry at Aberdeen University. There is reason to believe that the Readership in Forestry at Cambridge will, within a short time, be raised to a Professorship.

Flora of Shikotan.—To a recent meeting of the Linnean Society Dr. Hisayoshi Takeda contributed an interesting paper on the flora of Shikotan, the most southern of the Kurile Islands, which are between Kamtschatka and Yezo. Shikotan contains a number of high hills, and a considerable proportion of these are covered with coniferous and deciduous trees, others with dwarf bamboos. The vegetation of this island is in a quite primitive state. The number of the higher plants known to Dr. Takeda is 324, and belong to 213 genera and 62 families, of which 245, including eight new species, are new to the flora of this island, while 136 species are not mentioned in Miyabe's "Flora of the Kurile Islands," and 58 genera and eight families are additions to that work. Among plants which are common to Shikotan and Yezo, but not found in Saghalien, there are a number of plants which are distributed over North-eastern Asia.

Sheffield Botanical Gardens.—For some time past the beds and borders in these gardens have been resplendent with the rich and varied hues of early-flowering tulips, and the brilliant display of colour produced by the 20,000 or more plants have proved immensely attractive to the visitors. The principal varieties represented in the Sheffield Botanical Gardens are Belle Alliance, Cottage Maid, Grace Darling, Mon Tresor, Prince of Austria, Proserpine, Purple Crown, and Standard Royal. Mr. J. Bennett, the able curator, may be heartily congratulated on the success he has achieved in the arrangement of the colours.

Forest Trees and their Seedlings.—For some years past Dr. Zederbauer has been conducting a series of experiments at Mariabrunn, with a view to determine the influence of forest trees on their progeny. The trees used in the experiments were those of the Scots Pine. The results show that individual variations amongst trees depend partly upon the character of the situation and partly upon innate characteristics. Seedlings from trees possessing open crowns are faster growing than those from trees with more compact crowns. The average height of the former type of seedling at six years of age was 3ft. 9in., that of the latter 2ft. The age of the seed tree has a distinct influence upon the seedlings, which were about 6in. higher when raised from seed of young trees than when the seeds were obtained from old trees of the same habit. Seedlings raised from a vigorous Scots pine were free from leaf cast (Lophodermium pinastri), while the seedlings from a weakly tree of the same age were much injured by the fungus.

Amenities of Surrey.—Mr. J. St. Loe Strachey, of Newlands Corner, has presented a petition to the Surrey County Council urging the formation of an Amenities Committee, to which all public schemes undertaken by any public local authority within the county should be referred for its direction and advice. This reference is regarded as especially desirable in order that the committee may make recommendations as to the way in which contemplated improvements and developments can best be carried out without injury to the natural beauties, rural amenities, and architectural and historic monuments. The petition further suggests that the Amenities Committee shall appoint district committees, which shall appoint parish committees or individual representatives in every parish.

TOMATOES OUT OF DOORS.

Tomatoes in the open air are admittedly a most precarious crop, and their success or failure depends essentially on the nature of the climatic conditions that are experienced. Two years ago we had practically ideal weather for outdoor tomatoes, and some excellent crops were secured in many gardens. However, if we leave out of consideration the uncontrollable influence of the climate, there is no doubt that careful and judicious handling of the plants, especially when they are in their earlier stages of growth, goes a very long way towards ensuring success in this culture.

Preparing the Plants.

Chief of all things, perhaps, is the necessity for having the plants forward and in active growth as early as possible in the season, so that they may be sufficiently advanced in growth and hardened in constitution to be ready for putting out at the first favourable opportunity. This will not occur until all danger of their being cut back by frost has passed. But, while urging the necessity for hardening off the plants early in the season, it must be borne in mind that if this is overdone, the plant's growth is restricted, and it will become starved and weak in consequence. Nothing must be done that would tend to check their free and active growth in this manner, for under such conditions, it would be a long time before they could recover sufficiently to recommence active and vigorous growth, however favourable may be the soil and the method of preparing it for their reception.

Unfortunately, growers do not always give proper attention to soil conditions in open-air tomato culture. Frequently, the mistake of placing healthy and forward plants in heavy, retentive soil is made. The temperature of the soil under such circumstances is invariably low—much too low for the tomato plants, and there is, moreover, scarcely anything to encourage healthy root action. So, the plants cannot make headway, for this vigorous root growth is absolutely essential if they are to develop a strong and sturdy habit early in the season. Therefore, in preparing a soil which is naturally heavy and retentive, and lacking in a sufficient proportion of humus, there is no better plan than that of working in the ground a mixture of thoroughly well-decayed manure and leaf-mould, to which a little sand has been added.

The better the rooting medium for tomatoes the more forward and vigorous will be the growth of the plants. Yet, at the same time, it is more advisable to keep the roots well to the surface rather than run any risks of a low soil temperature; afterwards they may be earthed up and given a top-dressing of some suitable material. It must be remembered, however, that where the roots are kept near to the surface and the plants so exposed during periods of drought, there is a greater risk of flagging, due to lack of moisture. Here it is essential to give waterings through the surface mulchings.

Planting.

Well hardened tomato plants should be ready for planting out by the end of May or early in June, when they should be upwards of 6 or 7in. in height. They must have plenty of air during the day, closing the frames early and protecting with straw or matting if the plants are at all tender. Soft plants sometimes do well after being planted, but more often than not a touch of cold weather crops up in June, and checks them very severely, so that in some cases they are killed altogether. If the plants are standing thickly in the frames, ready for planting, it is very essential to prevent their rooting through into the medium on which they are standing; otherwise there will be a serious check when they are eventually moved. For planting, failing walls or fences, the rows should be marked out 18in. apart, and the tomatoes planted with a trowel at 16 or 18in. apart in the rows, a good watering being given after planting to complete the work.

Training.

Some growers use sulphate of iron for outdoor tomatoes, this fertiliser being finely ground and used at the rate of 1lb. to the pole, the manuring being done before the plants are put out. If the soil generally bears an unusually good crop of tomatoes, it is well to make the rows somewhat wider apart, placing a 5ft. bamboo cane for each plant as it is set out. Then a tightly-stretched wire can be tied to the canes at a height of 4ft. Only two or three trusses should be allowed on plants growing in soil not particularly favourable or productive of a good bearing crop of outdoor tomatoes, and then the plants should be stopped for good. Peat moss manure makes an excellent mulching for the plants as soon as they have been put out, and if this material has been well heated it should be given as a surface mulching as soon as the water given

STYRAX WILSONI.

A distinct and beautiful Chinese species of small growth, and bearing a profusion of white flowers. A.M., R.H.S., May 2. Miss Willmott, V.M.H., Great Warley.

to the newly set out plants has soaked in. There will then be little need for a further supply of moisture for some time to come.

Of course, the plants must be kept to one stem only, and great care must be exercised in staking, and finally in pinching back the growth so that the strength of the plants may be restricted. The top of the main stem must be pinched out when it is as high as the stake.

Spraying.

Spraying is particularly important work in outdoor tomato culture. It should be commenced from the first, with the idea of keeping away disease, or preventing it from developing if it is present in an inactive condition in the plants. A good Bordeaux mixture is about the best material for this purpose. In the case of the much-dreaded sleeping disease, where the leaves droop successively from the base upwards, increasing daily, and sometimes accompanied by discoloration, it is essential to remove any plants that show the disease and burn them at once. The soil in which they have been growing should also be sterilised with quicklime. Potato disease is a likely menace to tomatoes growing in the open, and in seasons when there is much of this disease about constant attention must be given to spraying. No other method is available for preventing attack by potato disease, Bacillus botrytis, Peronospora omnivora, Sclerotinia sclerotiorum, Fusarium Solani, Fusarium Lycopersici, and Curl, or Macrosporium Solani.

Varieties.

The old-fashioned Magnum Bonum tomato was grown very extensively years ago in the open ground, but now it appears to be somewhat out of date; yet at the same time it is difficult to beat for cropping and quality of fruit, and the individual fruits are probably heavier than those of any other variety. Sutton's Magnum Bonum is, in my experience, one of the best early varieties, and sets its fruit very freely. In selecting any variety of tomato for open-air culture, the most important thing to bear in mind is its constitutional characteristics. Some kinds possess the hardiness and strength of constitution, which fit them for exposure in the open, but others do not, and it is in selecting well-known varieties belonging to the latter class that so many growers made mistakes in outdoor tomato culture. Almost every nurseryman has his own special strain of outdoor "toms," and, as an example, Laxton's Open Air is still one of the best smooth-skinned varieties. It fruits most abundantly when carefully tended, and produces immense clusters of medium-sized good-flavoured fruit. In Jersey, Dreadnought is a popular open-air tomato, but one does not need to go into details; almost every experienced grower of outdoor tomatoes swears by his own particular strain, and nothing could be better, for he knows that it gives him the best results under certain conditions, and his experience in this direction does not tempt him to make any changes. J. C. Newsham.

Climbing French Beans.—This type of bean is not so widely cultivated as its merits deserve; its cropping powers are enormous, and carried over a considerable period, under proper treatment. A sowing in well-prepared trenches may now be made. The rows should be 6ft. apart, and the plants 7in. apart in the row. In colder districts it would be advisable to sow in boxes, which should be placed in a cool house or frame, and planted out after being properly hardened off.—W. Messenger.

FLOWERS AT HAMPTON COURT.

Tulips here, there, and everywhere formed the dominant feature of the floral display at Hampton Court during the Whitsun holidays. It must not be thought, however, that, though tulips predominated, they monopolised the display, for in the majority of cases they were associated with some other flower or flowers.

Many pleasing combinations were noted, and mention will be made of a few. The long border, stretching from the Palace towards the main road, along which the trams pass, is planted with a grand selection of May-flowering tulips, disposed in good-sized blocks or masses of each kind. In this way the collective effect of each variety can be seen, while their beauty is considerably enhanced by the judicious selection of flowering subjects with which they are associated.

For instance, special mention may be made of the beautiful dark salmon-rose tulip Edmee, springing from a mass of the sulphur wallflower Fairy Queen; Inglescombe Pink, with a carpet of yellow polyanthus; La Candeur, plentifully sprinkled over a groundwork of Aubrietia purpurea; Prince of Austria, associated with crimson wallflowers; Whistler, a scarlet variety, over double white arabis; the charming Elegans alba, carpeted with the rich-coloured aubrietia Lloyd Edwards, Pride of Haarlem, a rich rosy-scarlet flower, associated with White Gem wallflower; La Tulipe Noir, with yellow wallflowers; Rose Mignon and dark polyanthus; Mr. Farncombe Sanders, associated with Anemone coronaria; Blushing Bride, with a carpet of the beautiful yellow Alyssum saxatile; and Prince of Austria, with White Gem wallflower.

Where all are so beautiful it is difficult to select any for spepcial mention, but the following beds call for recognition in some way. A bed of standard plants of Azalea mollis, carpeted with dark pansies, over which is plentifully scattered the graceful Tulipa elegans alba. The bright-coloured tulip Mr. Farncombe Sanders overtopping the yellow wallflower. Aubrietia Dr. Mules and a white daisy in association as a groundwork to the single white tulip La Candeur, tulip Clara Butt, carpeted with double white arabis and Nemophila insignis mixed.

Alyssum saxatile with dot plants of Cytisus præcox and pink tulips. Nemophila insignis and the little red daisy Mavourneen. A very fine purple wallflower, lit up with tulip White Joost van Vondel.

Though wallflowers of different shades are numerous at Hampton Court, one bed viewed at a distance was, from its tone of colour, somewhat of a puzzle. Close attention revealed the fact that it was planted with that showy annual Erysimum Perofskianum, whose wallflower-like blossoms are of an intense orange tint. Tulips Europa and Grace Darling were associated with it.

The Hampton Court strain of polyanthuses fully uphold their reputation; in fact, they are this season much finer than last year, as the tropical summer of 1911 tried these plants very much. With masses of tulips stretching as far as the eye can reach, a question that suggests itself is how many bulbs are planted in Hampton Court Gardens alone?

The beauty of these gardens by no means depends upon the floral display alone, as the rich verdure of the lawns, the tender green of the unfolding leaves of the limes, which are so numerous, and the sombre-tinted yews, which stand out like sentinels over the expanse of grass, all combine to form a charming spring feature.

Altogether it may be said of Hampton Court Gardens at the present time that they fully maintain their good name, and in some features go much beyond it. Every praise is due to Mr. W. Marlow, who furnishes the gardens with so many delightful floral pictures at different seasons of the year. W. Truelove.

ROYAL GARDENERS' ORPHAN FUND.

Rarely has an annual festival dinner of this excellent charity passed off so successfully as the one held under the genial chairmanship of the Right Hon. Colonel Mark Lockwood, M.P., at the Hotel Cecil, on Thursday, May 15. The chairman was well supported by Messrs. N. N. Sherwood, E. Sherwood, H. B. May, D. Ingamells, P. R. Barr, G. Cuthbert, Wm. Cutbush, J. F. McLeod, W. Poupart, R. L. Wright, G. Gordon, R. H. Pearson, W. Howe, T. Bevan, Witty, Anderson, G. Monro, E. Rochford, G. Ingram, W. Leach, W. P. Thomson, R. Wallace, W. Nutting, A. Turner, W. H. Lees, G. Reynolds, A. Dimmock, C. Dixon, A. Bunyard, Cull, Cox, W. H. Page, etc.

The dining-room was beautifully decorated by Mr. R. F. Felton, with flowers and plants kindly supplied by friends of the institution, roses, carnations, tulips, and irises being the chief subjects used.

As is usual on these occasions the loyal toasts were given and honoured before "fumigation" was allowed or the musical programme commenced. The Chairman, in giving "Prosperity to the Royal Gardeners' Orphan Fund," suggested that his remarks were "interruptions" in the programme, because he was quite sure everyone present knew far more about the charity and its work than he could tell them. With brilliant touches of wit and humour Colonel Lockwood referred to the widening love of gardening, to the enormous amount of pleasure provided for others by gardeners, to the modest pay gardeners received, and to the deplorable fact that even among such healthy folks as gardeners there were many who passed away in the midst of life, leaving behind them a widow and children unprovided for. For these orphans the Chairman pleaded most earnestly, and subsequently he had the very great joy of hearing that his appeal, coupled with the efforts of the committee and friends, resulted in the addition of £1,245 to the funds. Mr. Edward Sherwood, the treasurer, responded, thanking the chairman for his presence, sympathy, and help. He gave a few particulars, and stated that the fund had distributed £27,495 in the assistance of orphans of gardeners, and last year its grants amounted to £1,796. The amount of good done was limited by the funds at the disposal of the committee, and he once more asked the press to kindly urge upon gardeners their responsibilities in this connection, and the desirability of larger numbers becoming annual subscribers, so that the fatherless children might be fed, clothed, and given a fair start in life. It was a most effective straight-from-the-shoulder speech that the Treasurer made, and we hope that his earnestness will meet with that response he so greatly desires.

Mr. N. N. Sherwood ably proposed "The Visitors," and an equally able response came from the Hon. Thos. Mackenzie, High Commissioner (and formerly Prime Minister) of New Zealand.

Mr. H. B. May gave "The Chairman," and this toast met with a hearty reception.

A capital musical programme was carried out under the direction of Mr. Turle Lee, Miss Kate Rooney, Miss Doris Cowan, Mr. Alfred Heather, and Mr. R. Johnson singing admirably, while Mr. Valentine Hill told humorous stories. "Auld Lang Syne" seemed to come all too early, thus proving that the meeting had been most successful.

We may add that the Chairman gave 20 guineas, Mr. Sherwood and his sons £105, Mr. Newton Mappin £50, Mr. Leonard Sutton £50, and Sir F. Crisp, £30. The various members of committee collected noble sums, and the Covent Garden friends contributed magnificently through Mr. D. Ingamells (Flower Market, £105 10s.), Mr. H. L. Wright (Fruit Market, £33 17s.), and Mr. W. Poupar (Vegetable Market, 20 guineas). Various seedsmen and nurserymen also contributed handsomely. We congratulate all who took part in the proceedings.

NEW PLANTS AND FLOWERS.

PÆONY LA LORRAINE.

This pæony will, we feel, eventually occupy a high position in gardens and may prove to be the forerunner of a quite new race. It is a tree pæony, but, as seen, is comparatively dwarf and very bushy. The parents are the new Pæonia lutea and the salmon-coloured variety of P. moutan named Princess Elizabeth. The flowers are large, about six inches across, very double and of a beautiful salmon-tinted buff shade. To all intents and purposes it is a yellow tree pæony, and we understand that it is quite hardy, and flowers later than P. moutan, opening in the ordinary way during the first week in June. Pæony La Lorraine was the most conspicuous new plant at the great Ghent International Exhibition, held from April 26 to May 4, and was raised and exhibited by Messrs. V. Lemoine and Sons, Nancy, France. F.C.C., R.H.S., May 13. Messrs. J. Piper and Son, Barnes and Bayswater.

ODONTOGLOSSUM PHŒBE SPLENDENS.

A very fine variety in which the individual flowers have been greatly glorified by the use of a large blotched O. crispum as one parent. The flowers are white with a few dark maroon blotches. If this should produce a large branching spike like the more typical forms of the hybrid it will be a most magnificent orchid. A.M., R.H.S., May 14. Messrs. J. and A. McBean, Cooksbridge.

PÆONY LA LORRAINE.

Flowers rich salmon, tinted buff. F.C.C., R.H.S., May 14. Messrs. Piper and Son, Barnes.

ASTER PURDOMI.

A species found at considerable elevation in the province of Shensi, China, where it was collected by Mr. Purdom. The plant is about nine inches high when in flower, and has lowly tufted growth. The flower heads are a pleasing shade of violet, measure about 1¼ inches across, and seem to be produced fairly freely. This aster should prove a valuable plant for the rock garden. A.M., R.H.S., May 14. Messrs. Jas. Veitch and Sons, Chelsea.

HELIOTROPE THE SPEAKER.

A splendid variety for pot culture. It has the large dense trusses seen in the variety Lord Roberts, but the colour is paler, and each flower has a distinct white eye. A vigorous variety that pleases the market growers. A.M., R.H.S., May 14. Mr. Philip Ladds, Swanley Junction.

CARNATION LADY INGESTRE.

This is a charming perpetual-flowering carnation, bearing smooth-petalled flowers of large size, light salmon-pink colour and delicate fragrance. A.M., R.H.S., May 14. Messrs. Wm. Cutbush and Son, Highgate.

RHODODENDRONS.

R. Wighti.—A fine Himalayan species, with large trusses of pale yellowish flowers, each flower carried on an unusually long pedicel. The trusses are terminal and the flowers campanulate; the ovate-lanceolate leaves are deep green above and red-brown beneath. A.M., R.H.S., May 14. Miss C. Mangles, Littleworth, Seale, Surrey.

R. Rose Queen.—A beautiful hybrid with goodly trusses of funnel-shaped, semi-drooping flowers, each bloom fully three inches long. The colour is a lovely shade of rose-pink, with an orange flush at the base of the tube. A.M., R.H.S., May 14. Miss C. Mangles, Littleworth, Seale, Surrey.

TULIP MASSENET.

A very distinct Darwin tulip, with stout, rounded flowers borne on sturdy stems. The colour is soft buff, with a deep flushing of rich rose over the centre of each segment. Seen against a dark background this is a very effective tulip. A.M., R.H.S., May 18. Messrs. R. H. Bath, Lim., Wisbech.

ROSE MISS FLORA MITTEN.

A strong-growing rambler rose bearing goodly trusses of single flowers that are of a delicate and beautiful shade of pink. R. Brunoni and the wild R. canina are the parents, and the child has a more or less perpetual habit of flowering. The flowers are about three and a-half inches across, and have a dense cluster of golden stamens in the whitish centre. A.M., R.H.S., May 14. Mr. J. Elliott, Hassocks.

ALOE MARLOTHI.

A strong-growing succulent plant, the stout stem bearing a rosette of closely-set leaves, each leaf about 1½ft. long, 6in. wide, and bearing a large number of brown-tipped thorns. The inflorescence is much branched, and the branches carry numerous cylindric flowers, yellow, with brown tips to the three inner segments. The stamens project half an inch beyond the perianth, and the filaments are bright violet. This species is a native of South Africa, and flowered last year at La Mortola. Bot. Mag., t. 8484.

PRUNUS PENNSYLVANICA.

Though said, by Aiton, to have been introduced in 1773, this North American species was unknown to Loudon in 1842. It is a free-flowering tree of slender growth, and rising upwards of 30ft. high. It blooms in April or early May, on the growth of the previous year, and the white blooms, each half an inch across, are carried in very short-stemmed umbels all along the growths. The little fruits are bright red when ripe. The species should make a good companion to the Bird Cherry, P. padus or P. avium, for planting in pleasure grounds or by woodland walks. Bot. Mag., t. 8486.

AMONG THE ALPINE FLOWERS.

"We turned our steps and loiter'd slow
'Twixt borders pale with later spring;
Polyanthus crowding ring on ring,
Love's banner, heartsease, balm for thought,
White tulips, blue forget-me-not."

H. C. Beeching.

The alpine lover is not content with possessing these flowers of the later spring in the borders alone, but they share the rock garden with other and less tutored flowers. We cannot do without the forget-me-not, even if we scorn some of the border forms, and replace the ordinary myosotis by M. Reichsteineri, the tulip by some of the smaller species, such as Tulipa linifolia, the polyanthus by the many charming primula species; the heart's-ease by Viola gracilis, and allow the fragrant balm to occupy some rougher corner, where its greater stature will better consort with a few of the bigger plants than associate with our daintiest gems of the alpine flora.

The alpine flowers of the time are truly many and beautiful, and as we loiter among them we feel that we cannot do aught but linger in their midst, rejoicing in their beauty and reluctant to leave their neighbourhood.

Androsace Chumbyi.

Labelled in strict botanical language by the somewhat cabalistic-looking designation of A. sarmentosa x villosa, this charming plant is better known to the alpinist as A. Chumbyi or A. sarmentosa Chumbyi, and, for convenience sake, we may well adhere to the former, a name well known and easy to negotiate in common conversation about our favourites. It is of the aspect of A. sarmentosa, although there are about its rosettes and general appearance traces of the influence of its other parent, A. villosa. Save in very wet parts of the country, where it may call for a covering of glass in winter to throw off the rain, it is as easy to manage as possible, especially if allowed to grow among chips and sand, with some free compost beneath, such as equal parts of loam, leaf-soil, or peat and sand with a mere trace of lime in some form in the soil. In a sunny place it will do well, but it is even prettier on the moraine, where its silvery-grey woolly foliage harmonises well with the chips and stones. In the moraine it seems quite happy, and is charming with its bright flowers of a warm pink or rose. Long ago it used to be the summum bonum of the alpinist to succeed with the androsaces, but many of them are not at all difficult, and A. Chumbyi is one of the easiest of all in sunny places where there is not too much wet to rot off the pretty rosettes.

Erythronium Pink Beauty.

Straying along a little narrow pathway, where the croziers of a small collection of good hardy ferns are unfolding, one stands long, and stoops oft to admire and inspect the lovely Erythronium Pink Beauty, said, I believe, to be a variety of E. Johnsoni. As one gazes at it one feels impelled to call in the aid of all the choicest complimentary adjectives and similes to endeavour to do justice to this flower. With the background of rougher greenery and unfolding fronds, this erythronium is simply perfect in its beauty. How can one attempt to describe it? Handsome, marbled, glossy leaves, whence rise a stout stem carrying a coronal of exquisite flowers, exquisite alike in substance, form, and colour. It is scarcely possible to conceive a more gem-like flower. It seems almost casting a slight upon it to use the simile "gem-like," for no hard gem, however beautiful or dazzling in its brilliance, can vie in the mind of the flower-lover with this exquisite erythronium from across the Atlantic, with its tier of unsurpassable pink flowers. Yet such a beauty must condescend to be treated like other mundane things. It is happy in a cool spot in light soil with loam, peat, or leaf-soil and sand. To naturalise in some choice corner this would be a rare beauty, but where it grows best it is almost perfection in every way.

Lithospermum prostratum.

Not a novelty, by any means, but yet among the most beautiful of all the Gromwells, and, withal, the most generally useful, is Lithospermum prostratum, which it appears a crime to neglect, even though one has spoken of it before. Trailing down a slope of the rock garden, veiling the stones, with all their hardness, with its healthy, deep green foliage, starred with dark blue flowers, it is a picture which gives joyance to the beholder, and makes him more and more delighted with his flowers. It is hard to say whether the typical deep blue form or its charming variety Heavenly Blue, is the more delightful. Both are acceptable, and neither can well be dispensed with, once we have become their possessors. Yet they are not always easy to establish, and one frequently comes across good cultivators who confess themselves baffled by Lithospermum prostratum. One secret of success is, I think, to procure young plants, small in size, and to wait with patience until they extend. Some eight years ago I left a fine large plant behind in moving to my present home, and began with quite a small one. Planted in gritty and hard soil, without any lime in it, and facing almost south-west, it hung fire for a year or two, giving one cause for uneasiness many a time and oft but in the long run flourishing, and now giving an abundance of its lovely flowers. Less in size, but doing well in much the same position, Heavenly Blue promises to become as fine in the course of time.

Other Flowers.

What a prodigal abundance of bloom there is now! Saxifrages galore, mossy, silvery, and of various other sections, in red and white and yellow, some marvellously spotted; violas many, primulas in choice loveliness, aubrietias, arabises, drabas, Cytisus kewensis and other beauties of the race; narcissi still, fritillarias, late scillas, and many other choice things of all manner of genera, make the garden truly a pleasaunce of the early May.

S. Arnott.

Cucumbers.—It is of considerable importance in the cultivation of early crops of cucumbers to avoid overcropping these plants or exhaustion soon follows, and some time is required before they can be brought to bear satisfactory again. Pinch the shoots of vigorous young plants at each joint, but where they have been in bearing some time, or have been overcropped, allow a little extra growth to extend, and otherwise encourage the plants by light, rich top-dressings and frequent applications of weak liquid manure. Fumigate lightly on two or three alternate nights if greenfly should appear, always having the foliage dry prior to the operation. Keep the temperature from 70 to 75 degrees, and a bottom heat of 85 degrees, with a free use of the syringe. Plants grown in frames or pits with manure as bottom-heat do not require so much feeding as those grown on trellises in houses, as the roots penetrate the manure composing the hotbed, and make a more luxuriant growth.—F. Jordan.

AWARDED DIPLOMA & MEDAL AT THE ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION 1912.

WAKELEY'S CELEBRATED HOP MANURE PATENTED

THE ONLY RELIABLE & COMPLETE SUBSTITUTE FOR STABLE MANURE

Scientifically and Chemically Prepared.

In the form of a leaf mould, ready for use at any time in the same way and for all purposes that decayed stable manure is put. Goes further (1 cwt. equalling 15 cwts.), gives better results, is clean to handle, sweet smelling, and free from weeds, worms, etc.

Thousands of Testimonials. Particulars post free.

Sold in bags, 28lbs., **2/3**; 56lbs., **3/6**; 1 cwt., **6/-**; 5 cwt., **28/9**; 10 cwt., **55/-**; carr. paid to any station in England and Wales, or by carrier, London.

Of Nurserymen, Seedsmen, and Stores, or direct from

WAKELEY BROS. & CO., Ltd.,
68, BANKSIDE, LONDON.

Also **Wakeley's Ground Garden Lime**, 2/- bushel bag carr. paid 25 miles, or **1/6** carr. forward.

RAFFIATAPE.—To pass off green corrugated tape (that rots and fades) for this is to sell old seed as new. Raffiatape is bound with strong unfadeable cotton, which gives it great strength, durability, and, being two colours, it is never unsightly. Plants are as quickly tied as parcels, as it expands with growth. 1d. coils (ties up 150 plants); 6d., 1s., and 1s. 6d. reels. Samples and catalogue of all garden sundries. — C. E. WEST, Higham Hill, London, N.E. Please ask your seedsman for West's Patent Garden Sundries.

DOT PLANTS IN FLOWER BEDS.

From time to time there appear in the pages of The Gardeners' Magazine very charming illustrations of scenes in famous gardens. Beginners, and those somewhat inexperienced in the arrangement of plants in the flower garden in summer time, cannot fail to learn a great deal from the study of many of the flower beds shown in these illustrations, and from carefully reading the very clear and concise references to them.

Young gardeners a generation ago very rarely had an opportunity of seeing such beautiful reproductions, and were obliged to travel long distances to inspect the bedding-out at certain establishments. Now they can see still more distant ones (to them) as well in The Gardeners' Magazine.

The style of bedding-out varies a great deal every few years. At one time, of course, carpet bedding found much favour (and a tremendous amount of work for the gardener and his staff). Zonal pelargoniums, calceolarias, and violas had a long run of favour, and still enjoy it. Then came the less formal methods of arranging the plants in the beds, and more room for the gardeners' skill. A plantsman who had no difficulty in putting up charming groups in conservatories and greenhouses rarely experienced any in carrying out successfully the newer styles of bedding out.

Much judgment, however, must be exercised by those who are inexperienced, or the beds will present a very weedy appearance. I do not intend to deal at all with the groundwork plants in this note, as too much space would be required for the purpose, but simply with the preparations necessary in connection with three kinds of plants. Although there are many other kinds which are most attractive, I think these three very important, and should be included in all beds of medium to large size.

Fuchsias.

Half-standards—those two and a half to three feet high—and full standards should be used, and in the large beds both kinds may be judiciously disposed in the same beds. The beginner would do well to allow the shoots of the plants to make fair progress before he prunes, or, more correctly, disbuds, then he will not produce a too formal-shaped head. The latter should be well balanced, but not too stiff. It is best to plunge the pots containing the plants in the beds, so in good time they should be repotted so as to get them well established before the bedding out is done.

Bring on the new growth steadily in a warm greenhouse temperature, and pinch off the ends of some shoots to create a balance, but not so persistently as to induce a weakly growth, and, eventually, small flowers. Keep the leaves clean and free from red spider and thrips. Gradually harden the plants from the first week in May, and have them ready for planting by June 10.

Bougainvilleas.

Straggling shoots of these may now be pruned back to an inch of their base; young shoots will soon grow; other branches may be tied in a little at present so as to cause them to droop gracefully. Of course all ties must be removed when the plants are put out as only central supporting stakes, neat and well placed, should be allowed.

To encourage a free growth keep the plants in a day temperature of 68 degrees, with a rise from sun heat, and a night temperature of 60 degrees. Syringe the branches on bright mornings, and repot any plants that require this attention. Loam, leaf-mould, rotted manure, old lime rubble, and sand will form a suitable compost; pot firmly. When the new shoots are six to nine inches long give the plants greenhouse treatment, and duly harden them in May ready for planting out a few days after the fuchsias.

Plumbagos.

Although the blue-flowered form is the favourite, the white one, P. capensis alba, should also be grown. Rather severe pruning may be carried out, as old plants, which are the best, produce nice flowering branches when so treated. Old specimens may be repotted in a mixture similar to that recommended for bougainvilleas, when the new shoots are three inches long, but young plants must not be repotted, or they will make too much wood, and bear few flowers.

Full standards of the two last-named kinds are the best for effect in large beds, so that their long, graceful, well-flowered branches may depend in a natural manner, and produce the best effect possible. Harden the plumbagos in the same way as the others. It is important that all the plants should have plenty of light while under glass.

RHODODENDRON ROSE QUEEN.

Flowers rose-pink, with orange flush at the base of the tube. A.M., R.H.S., May 14. Miss C. Mangles, Littleworth, Seale, Surrey.

APPLE PROSPECTS IN THE SOUTH.

Though it is too soon yet to form any proper idea of what the apple crop may be, there is always something interesting in a well-kept orchard at this season of the year when the trees are bursting into flower. One can take note of how the varieties are blooming, the time they expand their flowers, and the kind of weather experienced. Some varieties flower much earlier than others, and if the weather is favourable during the time they are in flower there is usually a crop of fruit.

In going through a large Sussex orchard the other day, I was struck with the way the trees were flowering, considering there were such heavy crops last year. Irish Peach, as usual, was the first to expand its flowers. I have known this variety in flower by April 7; this year it was the 20th before the trees were in full bloom. Following close on this variety was Bismarck; though this is not an early kind to ripen its fruit, it is one of the first to flower, and if the weather is favourable at the time we have usually a good crop of fruit. The long rows of trees, with their highly-coloured flowers, look very promising at the present time. Next we came to a quarter planted with Golden Spire, and the flowers of these were fully expanded on April 23, so they were close on the others. Warner's King was just bursting its flower buds on April 25, while Beauty of Bath, which was growing close by, was showing well, but would not be in bloom for another week. This, though an early variety, is not one of the first to flower. Cox's Orange Pippin was a few days later. There is a large breadth of Lane's Prince Albert, from which several tons of fruit were gathered last year, and these looked wonderfully well, but the trees would not be in bloom for another week or more. There are some hundreds of trees of many of the leading varieties, most of which look promising.

When visiting this same orchard last year while the fruit was being gathered, one could not help but admire the very fine samples that were grown, and which met with a ready sale at remunerative prices. It is not usual for trees to bloom so freely every year, unless some pains are taken to regulate the crop, as in favourable seasons the trees are so loaded with fruit that they become exhausted, and therefore not capable of forming fruit buds for the next. Where the trees are looked over after the fruit has started to swell, and the crop is freely thinned, this assists the trees wonderfully, not only in maturing their crop, but in forming flower buds for the following season. In the case of the early culinary varieties, such as Ecklinville, Lord Suffield, and others with fruit that will cook well as soon as large enough for use, those taken off will far more than pay for the labour expended on them.

Spraying is another operation that should receive attention, for if the trees are thoroughly cleansed from all pests of every description, they will grow more rapidly and produce finer crops. From experience it has been proved that spraying has wonderfully assisted the growth of these trees. It is far better to have a moderate number of well-developed flower buds than a large quantity of weakly, deformed ones, which, should the weather and other conditions be all that one could desire, are incapable of producing fine specimens. The aim should be to so regulate the crop as not to have a glut one season and none the next. We all know that weather conditions play a most important part in fruit production, but it is the grower's place to assist nature where possible.

Spraying has become more general of late, especially among those who are depending on their crops for a living. Growers, too, are beginning to realise the advantage of grading their fruit, and sending only such samples to market that are likely to command good prices. There is much more satisfaction in being able to realise at once than be compelled to hold over until a more favourable opportunity presents itself, which may not come. Gathering and grading are two important items in this business, and unless these receive special care and attention it is seldom that the best prices are obtained.

H. C. P.

MOSS ROSES.

I am constrained to take up the cudgels on behalf of this charming section of roses, having noted with regret that they have, to a very large extent, "gone to the wall" during the past decade. The more aggressive beauty found in the other sections, which constitute a large and ever-increasing army, is, to a large extent, responsible for their downfall and neglect, not forgetting that they are practically ignored by the large societies. And yet it is difficult to conceive anything more exquisite than a white or pink moss ross in bud form.

It is true moss roses are rather "miffy" subjects, and in order to create and to maintain vigorous growth careful and constant care is required. I remarked a number of wonderfully fine specimens in a Devonshire garden a couple of years ago, and the owner assured me that enormous quantities of cow manure had been incorporated with the soil during the process of preparation, and, further, that it had been supplemented by a heavy annual dressing, together with a thick mulch in May. I gathered that the natural soil was greasy loam, and this seems to prove that a rich, highly-cultivated soil is essential to fine development.

With regard to the origin of moss roses, there does not appear to be anything like a consensus of opinion, although they are supposed to have sported from the old cabbage rose, and to have been introduced from Holland near the end of the sixteenth century. The most successful growers are of opinion that, in pruning, a portion of the branches should be removed in their entirety after the plants pass out of flower, and that each and all should be cut back severely the first season after planting.

Among varieties, Blanche Moreau is a great beauty of spotless purity, while the dark green moss is very abundant. White Bath, too, is very fine, and, perhaps, superior to the foregoing. Comtesse de Murinois is a magnificent variety, with large, flesh-pink flowers; rosy-blush colouring is represented in Gloire des Mossenses; and Celina, Venus, and Little Gem boast crimson and purplish-crimson hues.

Walter H. Aggett.

PERPETUAL-FLOWERING CARNATIONS FOR SUMMER BEDDING.

It is only during the past few years that perpetual-flowering carnations have been used for summer bedding in the flower garden, but the practice of planting them in this manner is on the increase, as they have been proved to be eminently suitable for outdoor culture in this country.

One advantage is they make a display of bloom over a much longer period than any other type of carnation, and they can be had in flower from the time they are put out until autumn frosts check their growth.

Now is the best time to plant out perpetual carnations for a summer display. The best plants for the purpose are those struck from cuttings twelve months ago, as they are strong healthy plants in 5in. pots, with a number of blossom buds ready to expand. This is the best type of plant to use for the purpose, although specimens that were rooted early in the winter can be planted, but these do not commence to flower until later in the summer. Plants that are required for summer bedding must be treated accordingly if they are to give the best results. They may be pinched later than those grown for winter flowering, and should be kept cool all the winter, even a cold frame, provided that damp can be expelled, will suit them well.

The soil must be well prepared for them by adding a suitable quantity of manure, and cultivating it deeply. Bone-meal is a valuable ingredient to incorporate with the soil, and it should be thoroughly mixed in as cultivation proceeds. Heavy, retentive soil is not ideal for carnations, and when this has to be dealt with, it is necessary to add a liberal supply of coarse sand, wood ashes, and old mortar rubble, so as to bring it to a more friable and porous condition. See that the plants are quite moist at the roots before being turned out of the pots, for if planted in a dry condition it will be difficult to moisten the soil about the roots again. Plant firmly, and allow a distance of fifteen inches between the plants, as they produce the best effect when planted fairly closely. Keep the shoots neatly tied as growth proceeds, and also pay attention to disbudding, and remove dead blooms promptly. Water regularly during hot, dry weather: liquid stimulants can be given with advantage. Ply the hoe between the plants occasionally.

If it is desired, a little more space may be allowed betweeen the plants, and the ground carpeted with iresine or alternanthera: beds so arranged always present a smart, neat appearance.

In conclusion, I would recommend the planting out of old stock plants that have flowered during the winter: any odd piece of ground will accommodate them, and they will produce a quantity of bloom for cutting.

As regards varieties, the following make good bedding plants: Britannia, scarlet: May Day, Winsor, Mrs. H. Burnett, and Enchantress, pink: White Perfection, white; and Mikado, heliotrope.

J. Gardner.

Pentas carnea.—This is a useful soft-wooded flowering shrub, and may be bloomed at almost any season. Cuttings of the young wood are quite easily rooted, and may be grown on into five-inch pots, pinching the points once or twice to obtain a bushy growth, then allowing them to bloom. When the flowers are past their best the spikes may be removed, and, given growing conditions, the plants will grow freely, and will again bloom as freely as before.—H. Prime, Hatfield House Gardens.

NOTES FROM SCOTLAND.

Atmospheric Influences.

The past winter has, judging by reports that have from time to time appeared in the pages of The Gardeners' Magazine, been an unusually variable one in respect to the weather. In general an excessive amount of rainfall has been recorded. In Scotland it has dealt very harshly with all closely connected with land, be they of the horticultural or agricultural fraternity, and as a sequence, work of most kinds, especially that of seed-sowing and the planting of potatoes is greatly in arrears.

Worse still, however, is the amount of damage that in places has been done by flooding, where, owing to the abnormally swollen state of the river courses, the water have overflowed the banks or have made breaches in them, through which the stream rushed carrying destruction everywhere in its wake, making inland seas over wide areas. This, occurring as it did at mid-winter, was viewed philosophically, there being at that time little but the root crops (turnips) to sustain damage, but to have another and still worse inundation in May, when crops in general were sown, as was the case a few days ago, and in some extreme instances to remain for some time, is something unprecedented and disheartening.

Land thrown up in ridges and planted with potatoes, or in others much wider and sown with cereals, was by the action of the water levelled to its former state, and the seed crops swept away or laid bare, while in places the soil itself has largely disappeared. While one must heartily sympathise with farmers or market growers of vegetables, who in this way have lost portions of their crop, time, and labour, the allotment holders and owners of small gardens who, in some instances, have lost all, really seem entitled to a still larger share. Mid-Scotland has suffered most: here the rainfall was heavy and almost continuous for several days, and several of the rivers, being quite unable to contain the volume of water precipitated as rain, conjointly with the largely augmented sources rushing from neighbouring hills, soon overflowed, endangering life and property to an unusual extent.

Fruit Prospects.

The blossom on most kinds of fruit trees and bushes has for the most part been abundant, while the foliage where this is in evidence is clean and free from insect pests, due no doubt to the frequent washings it has been subjected to for some time past. Gooseberries and currants of all kinds will without doubt bear heavy crops; while strawberries and raspberries look very promising, and are so late in opening blossom that they should escape frost. This, however, has so far been an ideal season in this respect, very slight frosts, in some favoured districts not any, having been experienced for weeks past. Plums promise well, and plenty of fruit has set, which the weather continuing favourable for the remainder of the month should swell off satisfactorily.

Pears bore a large amount of bloom, but it was evident that a great deal of it was useless, being small, flimsy, and wanting in respect to the productive organs. Apples are not yet conspicuous except a few early kinds or others against walls There is one feature connected with these that is by many not considered a favourable omen, namely, the foliage is quite in advance of the bloom, a point which is regarded by long experienced practitioners as unfavourable to a good set of fruit.

Apple Golden Spire.

I was somewhat surprised a short time ago to discover what a strong hold this variety now has upon Scotch growers for market, one of whom had beheaded a large plantation of mixed varieties and regrafted the whole lot with this. The explanation, which was freely given, was to the effect that the variety was always fruitful, so much so that thinning of the crop to ensure the desired size was advisable. This is easily accomplished in the case of bush trees, and these, owing to free bearing, seldom attain any considerable size.

Furthermore, the fruit was early in reaching maturity, and, although not quite up to dessert standard, was sufficiently high in this respect to command the market early in the autumn before foreign supplies arrived; in this rested its chief value as a market fruit. James Day.

Dalry, Galloway.

Coprosma Baueriana variegata.—Time was when the variegated-leaved form of the New Zealand Coprosma Baueriana was grown more often than it now is. Apart from its value as an ornamental-leaved shrub for the greenhouse, it was often used for bedding purposes during the summer months. The leaf is of a deep glossy green, and the variegation consists of a broad margin of gold. It is propagated by means of cuttings, but, with the possible exception of Luculia gratissima, I know of nothing so quickly injured if cuttings are allowed to flag before insertion as this coprosma.—K.

CHELSEA SHOW—WISTARIA MULTIJUGA VAR.
A large-flowered form, the colour purplish, exhibited by Messrs. J. Piper and Son, Barnes.

AURICULAS.

These flowers seem to be increasingly popular, and perhaps it may be of some value if an "old hand" gives a few of his ideas to those who wish to start growing them. There is no need to spend a great deal of money in order to form a collection, for, as in other flowers, many of the cheapest varieties are also the best. Let us take the grey-edged class first. Here George Lightbody, a variety raised over 50 years ago by Mr. Headley, is still pre-eminent: this, along with George Rudd and, perhaps, a few plants of Marmion, are all that a beginner need obtain. In white edges he must have Acme, Conservative, and Heather Bell. In green edges Mrs. Henwood, Shirley Hibberd, and Abraham Barker are cheap. In selfs he needs nothing but Mrs. Potts and Ruby; still cheaper. If he grows these well he can face any competitor on the show table.

But he may want more variety, so let him purchase Lancashire Hero and Olympus to add to his greys; Traill's Beauty and Mrs. Dodwell to his whites; Ossian, Orient, and Prince Charming to his greens; Mikado, Harrison Weir, Mrs. Phillips, Favourite, and Miss Barnett, to his selfs; and, if he has a liking for a yellow self, as I have, let him add Daffodil to the list.

Every auricula grower worth his salt raises seedlings. I do, and although I have not "set the Thames on fire," yet I still go on, for the pleasure of seeing seedlings bloom is very great. I have been raising seedlings for more years than I care to count, and my experience teaches me that it is best to keep greys to greys, whites to whites, selfs to selfs; and in the selfs as we want the blues bluer, the reds redder, and the blacks blacker, it is best to keep the three colours apart. I would advise would-be seedling raisers to try the following crosses:

G. Lightbody x Olympus.
G. Rudd x G. Lightbody.
Lancashire Hero x G. Rudd.
Shirley Hibberd x Mrs. Henwood.
Mrs. Henwood x Prince Charming.
Acme x Mrs. Dodwell.
Acme x Conservative.
Mrs. Potts x Favourite.
Mikado x Mrs. Phillips.
Harrison Weir x Ruby.
Daffodil x Buttercup.

James W. Bentley.

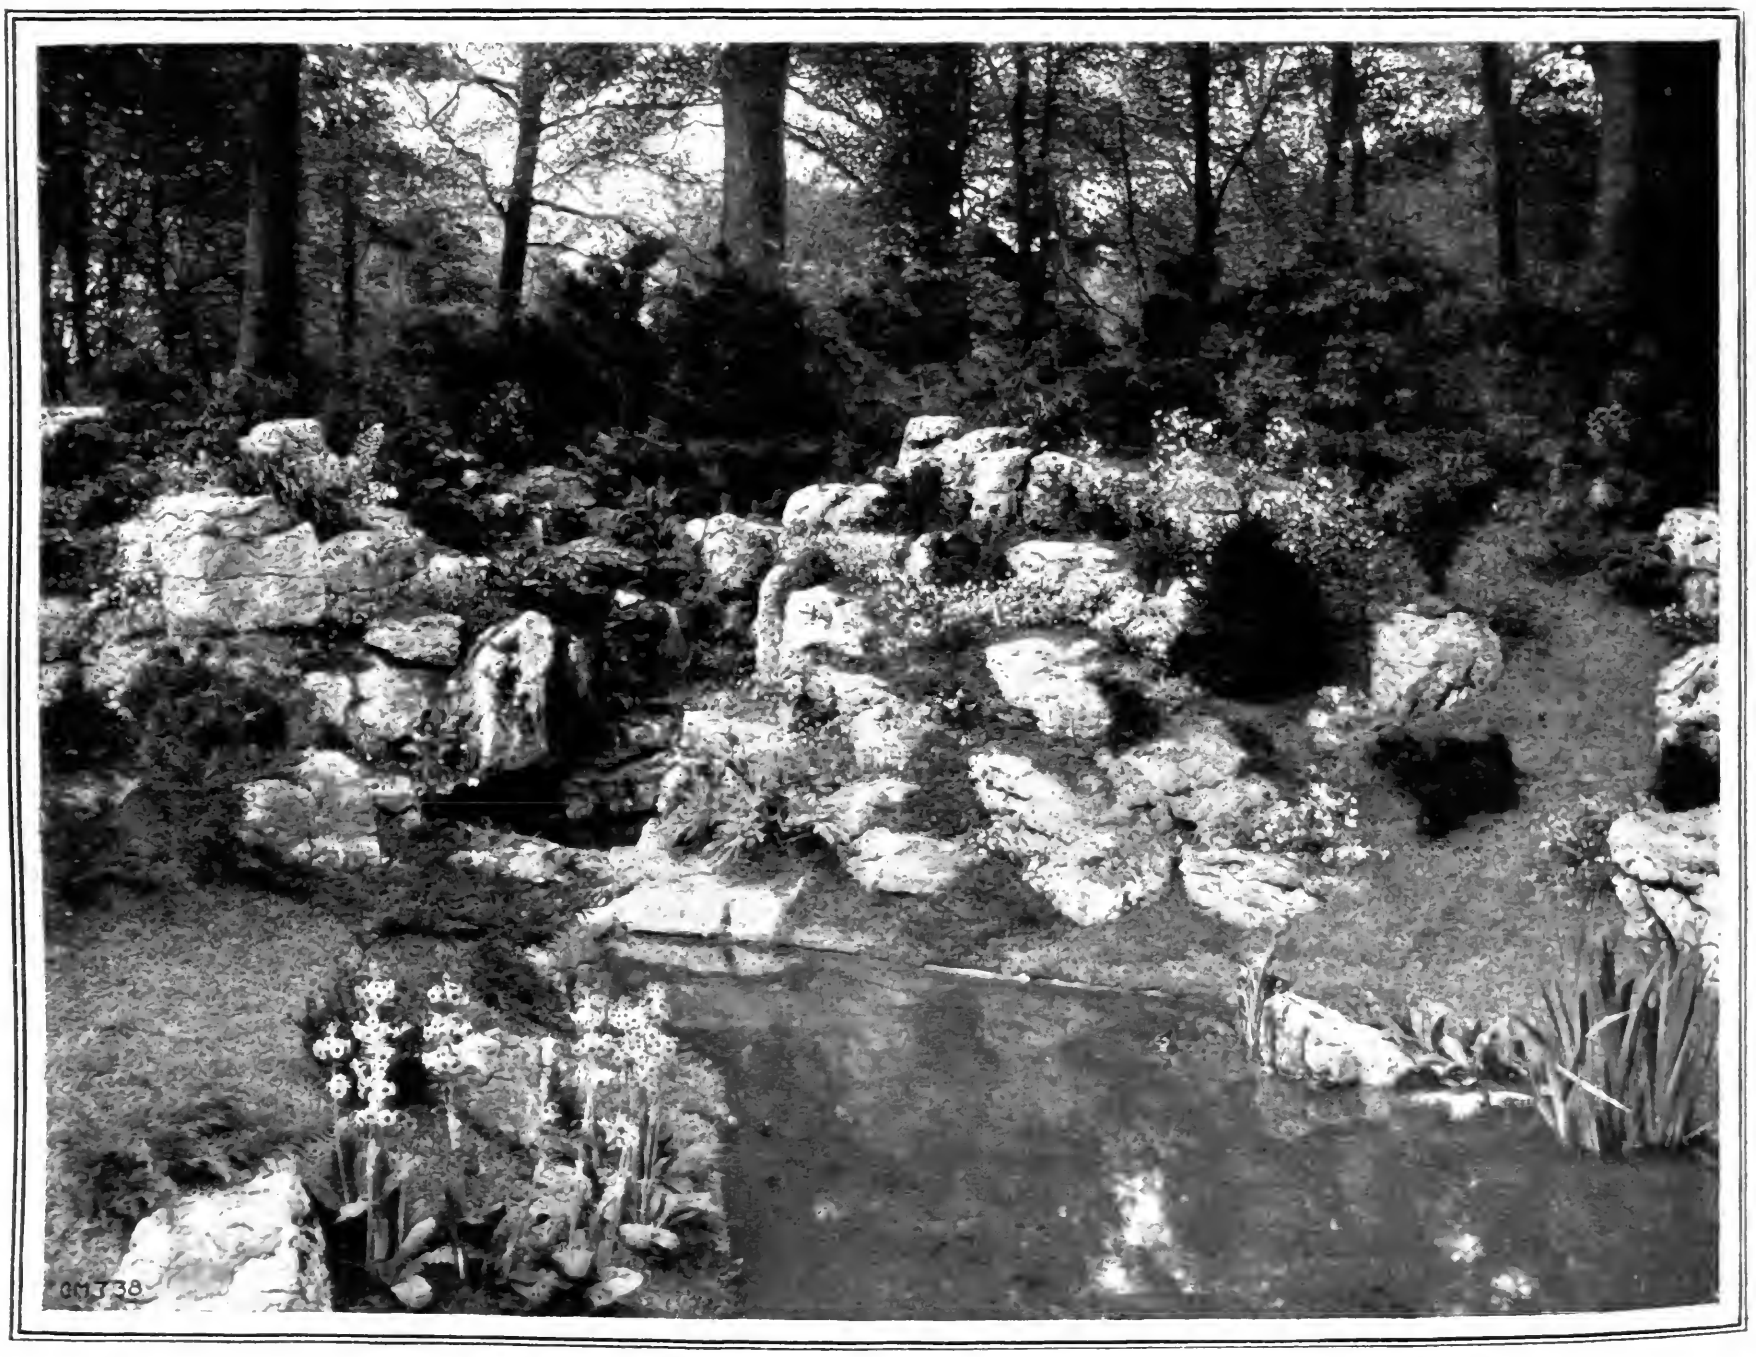
MORISIA HYPOGÆA.

Few will question the opinion that Morisia hypogæa is one of the most beautiful of our alpine plants, or will dispute the view of those who hold that every collection of such flowers of any pretensions should include this charming dwarf plant. It is very delightful, with its flat rosettes of finely-cut, shining leaves, and its bright little yellow flowers close set in the foliage, which so well displays the brightness and beauty of the little blooms. It is, indeed, a plant worthy of all praise. When we come, however, to speak of its cultivation, we are on more doubtful ground. It is not a troublesome plant in the ordinary sense of the term, but it is uncertain, and those of us who wondered at first that it has been lost to cultivation for years before its re-introduction, can understand why this was the case. What its duration of life may be is difficult to tell, but most people who have grown it become more and more chary of asserting that it is a long liver, although it is certainly hardy and perennial.

The writer knows of good cultivators who cannot retain Morisia hypogæa without propagation for more than two or three years. Others, again, can count the lives of some of their plants up to seven or eight years, yet, with hardly an exception, these cultivators admit that it is not absolutely reliable, and that it is well to keep a spare young plant or two for replacement, if necessary. It appears to matter little whether the soil be of almost pure sand or of a richer character; the Morisia may succumb in a year or two, or may survive for several years. There are, doubtless, some cultivators who may traverse this statement, but it has been advanced after long personal experience and comparison of that of others whose knowledge is entitled to consideration. Generally speaking, a light, well-drained soil of almost pure sand will suit M. hypogæa best, and there it is more likely to sow itself.

Its propagation by root-cuttings is easy. In early spring or in autumn a plant should be lifted, and a portion of its roots employed as root cuttings, cutting them up into lengths of about an inch, and inserting them in sandy soil, with the top part just at the level of the soil. When done in spring, it should be very early. The tops of these root-cuttings will soon show signs of growth, and, when rooted, the cuttings, which should be put round the sides of the cutting pot may be repotted singly into smaller pots and grown under glass before planting out.

S. Arnott.



CHELSEA SHOW—PART OF ROCK AND WATER GARDEN.
Constructed by Messrs. Wallace and Co., Colchester.

THE GREAT FLOWER SHOW AT CHELSEA.

To begin with, let us say that the great exhibition held in the grounds of the Royal Hospital, Chelsea, on May 20, 21, and 22, was a huge success, and proved beyond all question the great strides horticulture is making, and the great popularity enjoyed by the Royal Horticultural Society. We may remind those who visited the Temple Show of 1911—the last of a long and fine series—that the show held this week was three times as large as that one, and a much more comfortable function. Exhibitors, who numbered nearly 250, were grumbling, however, because they had insufficient space, and in some cases the gangways were all too narrow, especially one largely occupied by the row of pillar supports of the tent.

The greater part of the exhibition was held in the great tent familiar to those who attended the "International" in 1912, and the effect produced was better than last year. Orchids, roses, hardy flowers, masses of flowering trees and shrubs, fragrant carnations, gorgeous tulips, fruits, and vegetables formed the greater part of a wonderful display that covered the better part of three acres. Out of doors the rock gardens and formal gardens were extraordinarily fine, and gave ample evidence of British pluck and enterprise, for many hundreds of pounds had been expended upon their production—indeed, many of these designs looked as though they had been in position for years, and were intended to remain there for years to come.

Novelties of many kinds were in evidence, and these we shall refer to in detail, with illustrations in our next issue. The Orchid Committee had no fewer than eighty orchids placed before it for consideration for award, and other committees were equally busy.

ORCHIDS.

As at the great exhibitions held in previous years at the Inner Temple Gardens, orchids were an outstanding and brilliant feature, and the section to which all visitors turned sooner or later.

Dealing first of all with the display from amateur collections, the one so beautifully arranged by Mr. H. Alexander, grower to Sir George Holford, Westonbirt, Tetbury, Gloucester, at once attracted attention. Mr. Alexander showed magnificent plants, a large number of them being specimens of considerable size and splendid growth; moreover, every plant was set well apart from its neighbour, in an ample groundwork of maidenhair ferns; palms were used as a background, and green moss finished off the margin. Turning to the special subjects in this group (which, by the way, was not more than half as big as the superb International effort of 1912), we may

CHELSEA SHOW—LÆLIO-CATTLEYA BRITANNIA WESTONBIRT VAR.
Sepals and petals brilliant rose-pink, lip bright crimson-purple. F.C.C., R.H.S., May 20. Lieut.-Colonel Sir George Holford, Westonbirt, Tetbury.

make mention of several dozen spikes of the golden Oncidium Marshallianum, Cymbidium eburneo-Lowianum with two fine spikes; Miltonia vexillaria with 14 spikes and 59 flowers; M. v. Snowflake, with 15 spikes and 85 blooms; M. v. Marmorata, with 75 flowers; and M. v. virginale, with no fewer than 29 spikes and a total of 125 lovely flowers. Then there were the grand Lælio-cattleyas, notably L.-c. Fascinator, L.-c. Britannia Westonbirt var., with two spikes carrying eight superb purple-red and mauve-tinted flowers, and occupying the central position (see illustration); L.-c. E. S. Ball, L.-c. Ganymede Westonbirt var., and L.-c. Luminosa. The brasso-cattleyas, with their fine fringed lips, were a grand feature, twenty fine specimens being arranged, including B.-c. Digbyano-Mossiæ, B.-c. Digbyano-Schröderæ, B.-c. Queen Alexandra, and B.-c. Mdme. Hye. The cattleyas were fine, notably C. Mossiæ Mahomet, with fourteen richly coloured blooms; C. Schröderæ Geisha, white, and finely formed; C. Dusselplenty, Brasso-diacrium Colmani—a rare white hybrid, Cœlogyne Parishi, and Oncidium pulchellum.

Mr. Jules Hye, Conpure, Ghent, brought over the lovely Miltonia Hyeana var. Eureka, with crimson base to the rose flushed white flowers. From W. P. Burkinshaw, Esq., Hessle Hall (gardener, Mr. Barker), came Cattleya Lueddemanniana Schröderiana and Miltonia Bleuana Hessle var., the latter very handsome with its red blotch and yellow disk. Odontoglossum Othmarschen, grandly marked with brilliant chocolate-crimson, was finely shown by Baron Bruno Schröder (gardener, Mr. Shill), The Dell, Egham. Mr. Evans, Congleton, Manchester, also staged some grandly blotched odontoglossums.

Sobralia macrantha alba, a big specimen carrying over thirty pure white flowers, was a fine example from J. Gurney Fowler, Esq. (gardener, Mr. Davis), Glebelands, South Woodford, and probably the largest specimen of its kind. Also from the Glebelands collection came the rare, yellow-green Cymshapely flowers, heavily marked with soft red-rose on a mauve-tinted ground; O. Georgius Rex, with a splendid spike of thirty-two grand blooms over four inches across, with heavy crimson blotches on a whitish ground; Lælia purpurata Queen Alexandra, white; Lælio-cattleya Sylvia var. Princess Victoria Louise, with yellow flowers and ruby-tipped lip; Odontioda Diana, with grand rich red flowers, vermilion tinted; Brasso-cattleya Princess Elizabeth, pale silvery mauve; Miltonia Charlesworthi, a brilliant hybrid between M. Hyeana and M. vexillaria G. D. Owen, and with a wonderful crimson blotch at the base of the lip; Lælio-cattleya Golden Glory, Odontioda Lutetia, and beautiful examples of the brilliant O. Bradshawiæ, O. Charlesworthi, O. Chantecleer, and O. Keighleyensis.

A lightly arranged bank of orchids from Messrs. James Cypher and Sons, Cheltenham, merited attention, and indeed attracted it by reason of its beautiful masses of Oncidium Marshallianum and Renanthera Im-

CHELSEA SHOW—ROCK GARDEN.
Constructed by Messrs. Whitelegg and Page, Chislehurst.

-dorfei Undine; and C. Skinneri, with eight spikes. Of the odontoglossums we have only space to refer to O. illustrissimum Westonbirt var., with rose and red-brown flowers; A. armainvilliersense and Anthotes, O. crispum Zoroaster, A. Acme, and the finely-formed red-purple O. eximium King George.

A beautiful and very gracefully arranged group of orchids from Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate, was very greatly admired. Particularly pleasing was the central pyramidal arrangement of well-grown and good forms of Odontoglossum crispum, Odontioda Bradshawiæ, and O. Vuylstekæ, set over a groundwork of asparagus and moss. Oncidiums and rare miltonias were associated at one end, and cattleyas and Dendrobium Dalhousieanum at the other. A few of the choicest features of the group were Odontoglossum Queen of Gatton, with fifteen yellow and brown flowers; O. Vuylstekeanum, O. Phœbe splendens, Lælio-cattleya Boylei, the L. anceps hybrid with white, yellow-throated flowers; Odontoglossum Thompsonianum in bidium Woodhamsianum Fowler's var., with a pair of spikes.

Mons. H. Graire, St. Fuscien, Sains, France, sent over Odontioda Chelseaensis St. Fuscien with a spike of twenty large old-rose coloured flowers.

Messrs. Charlesworth and Co., Haywards Heath, had a bold and startling exhibit, the ends consisting of big mounds of fine varieties of Miltonia vexillaria from which arose spikes of white odontoglossums and Phalænopsis Rimestadiana. In the centre the fine old Lælio-cattleya Dominiana was massed in a big group, about a score of specimens being set up, with a background of coloured odontoglossums. In the bays between the miltonias and lælio-cattleyas, the odontoglossums and odontiodas were associated with Cymbidium Humbloti, Renanthera Imschootiana, Oncidium pulchellum, Dendrobium Phalænopsis, Cymbidium Pauwelsi, C. Alexandræ, etc. Of outstanding excellence were Odontoglossum Empress of India (see illustration), with a spike of nineteen large schootiana. All along the back Cattleya Mendeli, Lælio-cattleya Dominiana, L.-c. Fascinator, and C. Mossiæ were set up boldly amid ferns. In the foreground were miltonias and odontoglossums in abundance, with the white Phalænopsis Rimestadiana, the yellow Dendrobium Thwaitesi Veitchii variety, Masdevallia Veitchi grandiflora, Vanda teres, Cymbidium Alexandræ, and a mass of Cymbidium Mandiæ, Epidendrum bicornutum, Maxillaria Sanderiana, and the tall, orange-coloured Lælia Latona.

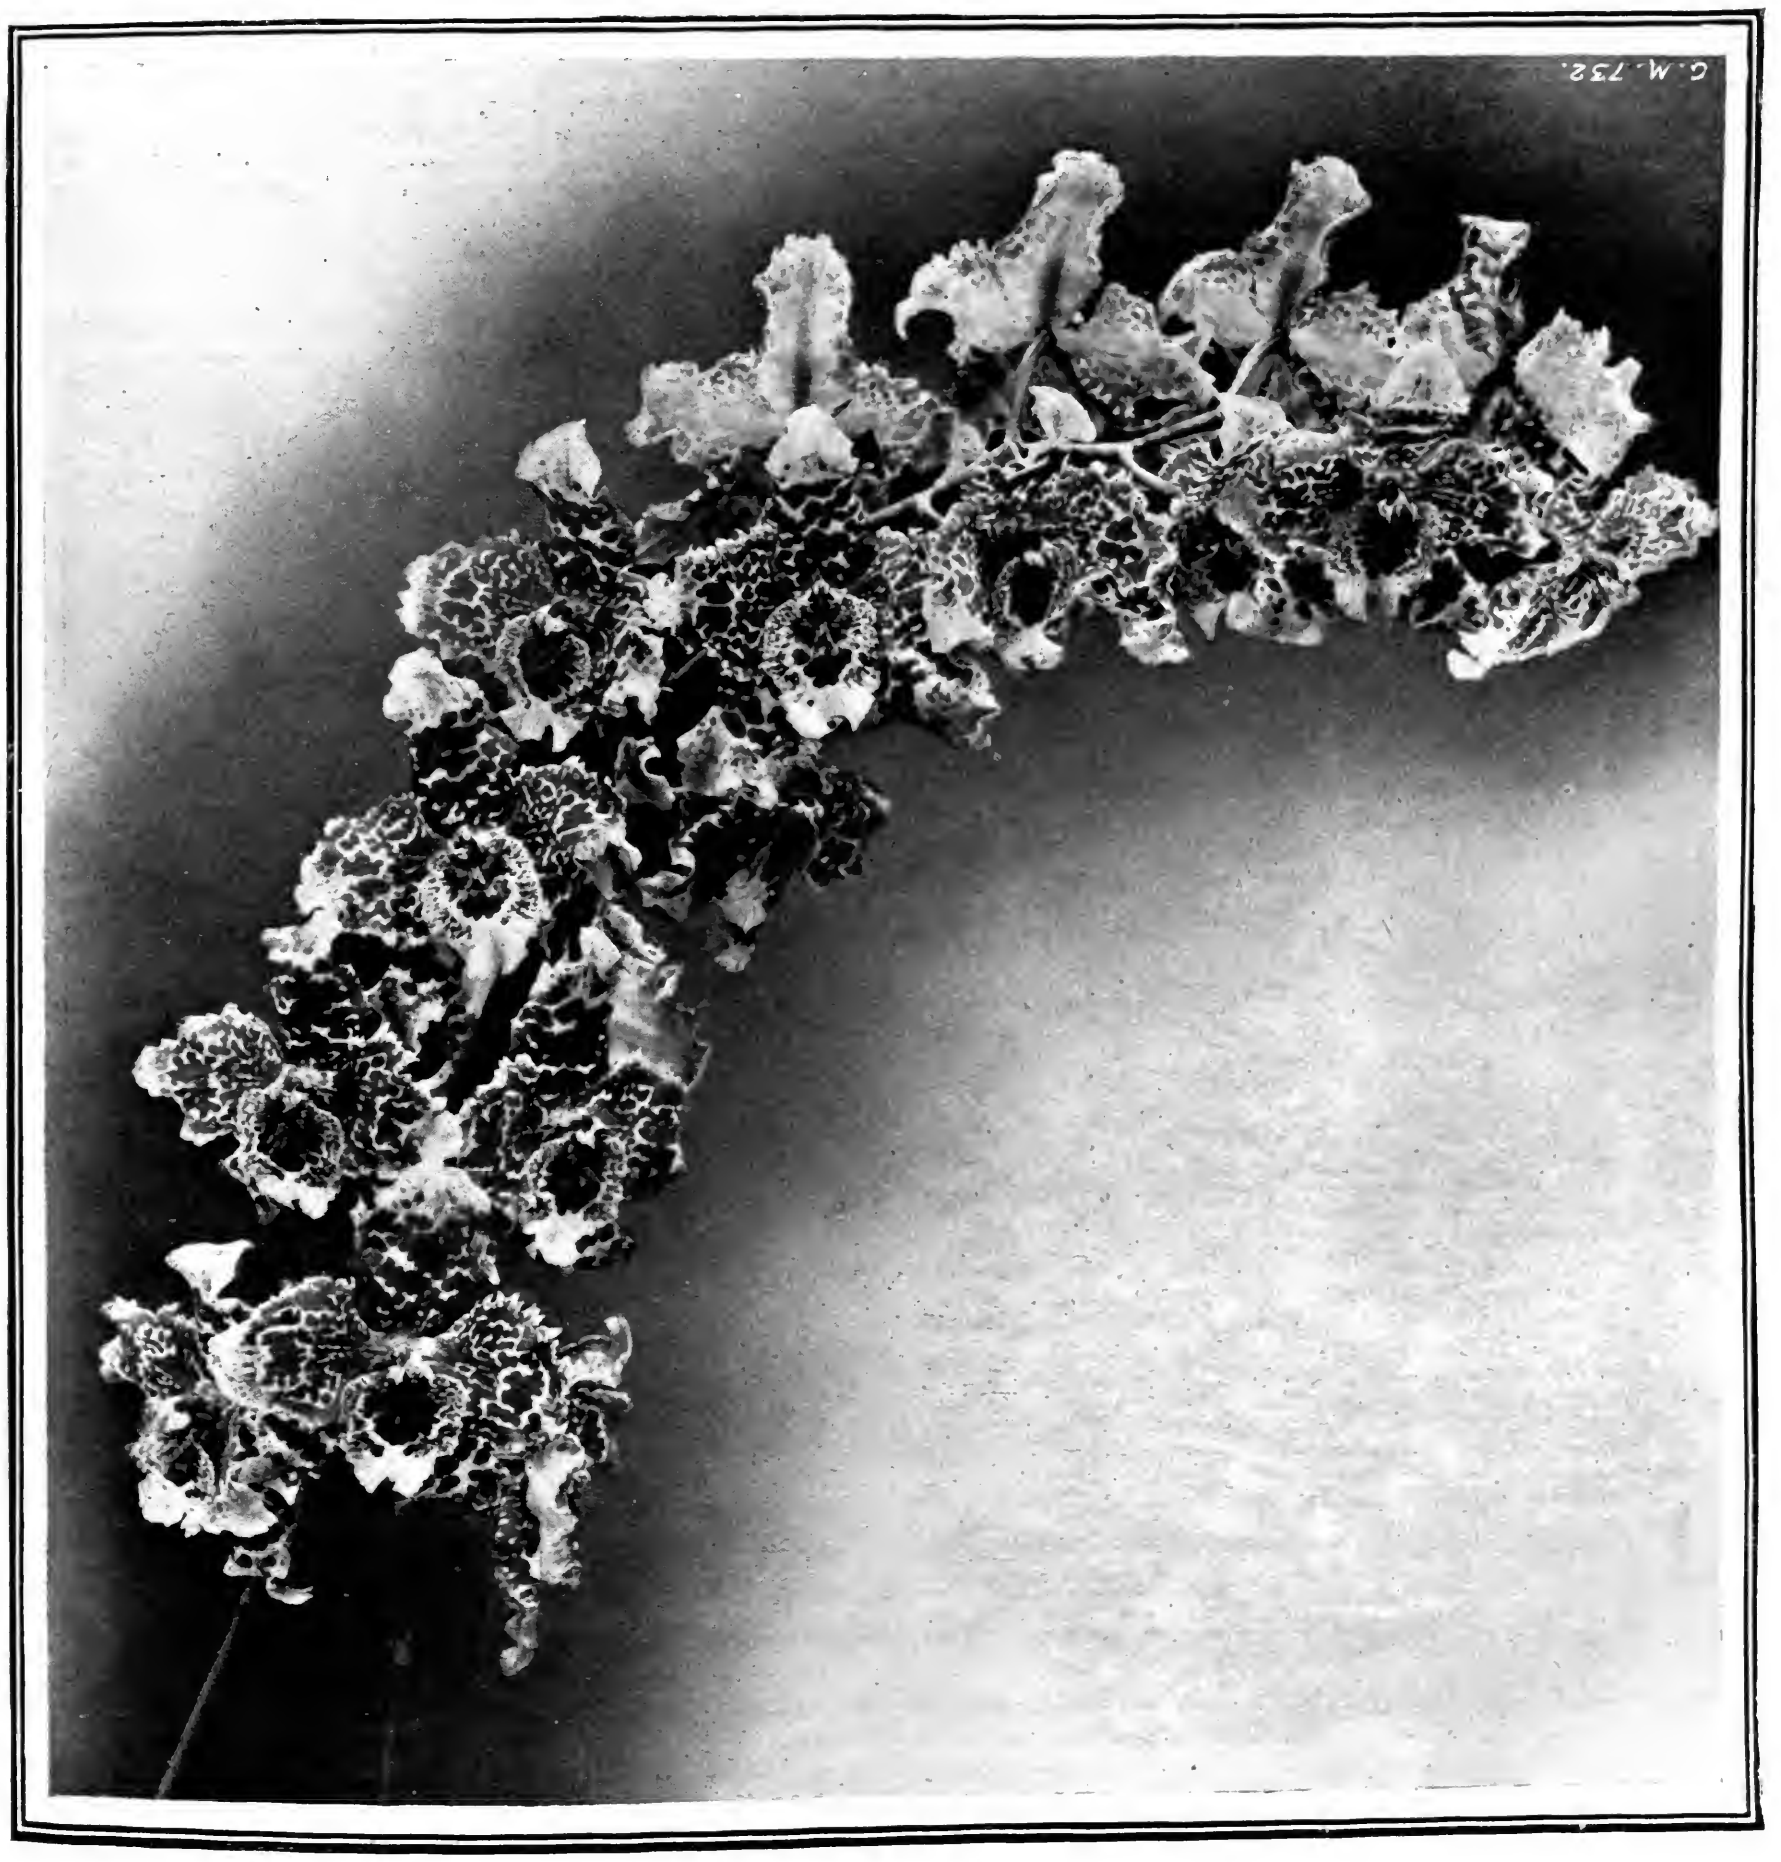
For elegance of arrangement, brightness, and the inclusion of many choice things, Messrs. Sander and Sons' group of orchids was of great excellence. We much admired the high light background, where Phalænopsis Rimestadiana, Cœlogyne Dayana, Renanthera Imschootiana, and Dendrochilum glumaceum were associated in high elegance masses on either side of a bold central group of cattleyas, Lælio-cattleyas, and Brassocattleyas, from among which rose spikes of Cymbidium Pauwelsi, C. Gottoianum

bellissimum, a lovely chaste variety, and various odontoglossums, odontiodas, etc. At the ends were masses of miltonias and odontoglossums. Picking out a few special subjects from this splendid collection we must note Brasso-cattleya Mrs. Leemann var. Diadem, with yellowish flowers, B.-c. mirabilis, the new Maxillaria Fletcheriana, L.-c. Imperator Regina, the wonderful Oncidium Cooksoniæ illustris, Cœlogyne pandurata, Miltonia St. Andre, with Odontioda Roger Sander, O. Lælia Sander, O. Deloscasæ var. Solon, all derived from Miltonia Warscewiczi, and an odontoglossum. Odontoglossum Conqueror, a sort of groundwork for fine forms of Cattleya Mossiæ, C. Dusseldorfei Undine, Odontioda Bradshawiæ, the lovely yellow Odontoglossum luteo purpureum Vuylstekeanum, O. Aireworth, and the pure white O. armainvilliersense. Dendrobium Bronckhardti and Lælio-cattleya Phœbe lent colour to the ends of this display.

Messrs. Armstrong and Brown, Tunbridge Wells, came out strongly with a large and beautiful exhibit set up in their best style. Masses of Cymbidium Lowianum marked the top corners, and fine spikes of Phalænopsis Rimestadiana arranged over Odontoglossum teresting green and black flowers; the quaint Bulbophyllum Ericessoni, Odontioda Chanticleer, Odontoglossum eximum Armstrongæ, with red-purple flowers on white ground; and Miltonia vexillaria G. D. Owen.

Mr. C. F. Waters, Balcombe, Sussex, had a low group that was pleasing to look upon after the many other high arrangements. He presented a host of light varieties of Odontoglossum crispum, forms of Lycaste Skinneri, Cattleya Mendeli, and C. Mossiæ, with a few renantheras, etc.

Cymbidium insigne towering up among bamboos formed the background of Mr. H.



CHELSEA SHOW—ODONTOGLOSSUM EMPRESS OF INDIA.

Flowers large, richly marked with rose-red on deep blush ground. Exhibited by Messrs. Charlesworth and Co., Haywards Heath.

O. crispum excelsior, fine white and shapely, O. perciltum Aerides Lawrenceanum, and Angræcum Sanderianum were other beautiful kinds on view.

Mr. Sidney W. Flory, Tracey's Nursery, Twickenham, contributed a rather flat bank of orchids, and the chief features of his display were good forms of Cattleya Mendeli, Vanda teres, Brasso-cattleya Queen Alexandra, heavily blotched odontoglossums, and a little set of the golden-veined Anæctochilus petola.

Messrs. Hassall and Co., Southgate, provided a graceful group, and carefully avoided the evils of overcrowding. Miltonias formed Thompsonianum formed the high central feature. Below the latter a grand lot of Odontioda Bradshawiæ, O. Rosefieldense, O. Charlesworthi, O. Vuylestekeæ, white odontoglossums and Miltonia Bleuana were beautifully grouped over ferns. A pair of good specimens of Cœlogyne Dayana were set high in the bays, and their long pendulous spikes hung over groupings of Lælio-cattleya Hyeana, L.-c. Mrs. Temple, L.-c. eximia, L.-c. Fascinator (a fine lot), Brasso-cattleya L.-c. Veitchi, B.-c. Leemannæ, and B.-c. Langleyense. In the foreground we were attracted particularly by Cattleya Skinneri alba, Cœlogyne pandurata, with its ever in-

Dixon's group of orchids, tall odontoglossums were also used at the back with choicer varieties, and some pretty odontiodas in front. Miltonias were well represented, and so were orange-coloured lælio-cattleyas.

Messrs. J. and A. McBean, Cooksbridge, had an extremely pretty exhibit that was also a large and handsome one. This firm grows odontoglossums grandly, and on this occasion used lovely spikes of light forms of O. crispum in great numbers, massing them at the back, ends, and centre, with grand groupings of Cattleya Mossiæ in the bays. Right in the front was a whole host of brilliant odontiodas and special odontoglossums.

Of the latter O. Vuylstekeanum, O. Clytemnestra, O. Mastiff, rich brown and white; O. King Arthur, rose and purple-brown; Cattleya Mendeli Mayflower, C. Mossiæ Dreadnought, Odontioda Lambeauianium, Odontoglossum Phœbe splendens, and O. Brightness, almost wholly of a rich red-brown colour.

The display made by Messrs. Stuart Low and Co., Enfield, was very attractive, and its outstanding feature was a stand of Phalænopsis Rimestadiana, Renanthera Imschootiana, and dendrochilums. Against a background of palms, Dendrobium Warderianum, D. thyrsiflorum, and Oncidium Marshallianum showed up finely, while in the valleys were D. formosum giganteum and Cattleya Mendeli. Oncidium concolor was very fine in the foreground, with miltonias, Odontioda Bradshawiæ, O. Lambeauianum, the dainty Cypripedium niveum, and the fragrant Cattleya citrina.

Another glorious exhibit was displayed finely by Messrs. Mansell and Hatcher, Rawdon, Leeds, the general design being three large mounds with two bays or valleys. At the ends Cymbidium Lowianum and white odontoglossums were set well above Lælio-cattleya Hyeana, L.-c. Aphrodite, L.-c. Fascinator, L.-c. Canhamiana, Cattleya Mossiæ, and C. Mendeli. In the centre cymbidiums were associated with the bright Renanthera Imschootiana, Cattleya Empress Frederick var. alba was a fine centre plant with beautiful yellow, brown marked lip. Oncidium pulchellum was very lovely all round the base of the central mound, while Miltonia vexillaria filled the valleys except where, in the foreground, we noted such choice things as Odiontioda Rosefieldense, O. Gaunti, rich vermilion, Odontoglossum crispum eboraicum, O. percultum, O. crispum Royal Gem, and the fine Miltonia vexillaria Chelseaensis.

Mr. E. W. Davidson, Twyford, contributed a nice lot of odontoglossums and lælio-cattleyas, and made up a very pleasing group of choice varieties of these and other orchids.

ROSES.

If there had been nothing else in the great show at Chelsea the roses alone would have repaid a visit, and the method of arranging the groups, which reminded one of the International Exhibition last year, was a great improvement on what one has been in the habit of seeing at the Temple. Varieties of the rambling types were the conspicuous feature, and these were represented largely in quite a variety of forms. Indeed, they went a long way to demonstrate the popularity of this comparatively modern section of the great rose family.

Messrs. W. Paul and Son, Waltham Cross, were represented by a beautiful group of roses. Weeping standards of many delightful varieties, which included Tausendschon, American Pillar, Blush Rambler, Hiawatha, Excelsa, Sylvia, Coquina, and Lady Gay looked down, as it were, on a groundwork of finely-grown pot plants, some of the most conspicuous of which were Madame Maurice de Luze, Marcella, Mrs. Joseph Welch, Sunburst, Portia, Arthur R. Goodwin, Entente Cordiale, and Antoine Rivoire.

A very effective group of roses, mostly ramblers was set up by Mr. George Prince, of Oxford. It would be difficult to imagine finer flowered specimens of Dorothy Perkins, Hiawatha, Lady Godiva, White Dorothy, and Minehaha than those represented in the group, while dwarf plants of Mrs. Cutbush, Jessie, Jeanne d'Arc, and others formed a pleasing ground work.

Roses in pots and roses cut made up the striking exhibit sent by Messrs. Frank Cant and Co., Colchester. Rambling roses of the Hiawatha and Dorothy Perkins types formed the background and sloping down in front of them were bold masses of Lady Roberts, Mrs. George Shawyer, and Mrs. John Laing. Specimen blooms in boxes reminded one of a summer rose show, and altogether the display was worthy of the high reputation of this firm.

Near at hand Messrs. Alexander Dickson, Newtownards, had a small but very choice exhibit of cut roses, which included Queen Mary, Mrs. Cornwallis West, Mrs. Campbell Hall, Verna Mackay, and Alexander Hill Gray.

Messrs. B. R. Cant, Colchester, filled a big space with roses. Ramblers were there in great profusion, both in pots and arranged in bamboo stands. Amongst the varieties of other roses which seemed to stand out most conspicuously were Elizabeth, Rose du Barri, St. Helena, very fine; Sunbeam, Sallie, a lovely rose; and Lady Reay.

Messrs. A. J. and C. Allen, Norwich, were exhibitors of a small group of roses, in which Sunburst was conspicuous, but the effect would have been better if there had not been so much material crowded into the space. A corner of one of the tables was occupied by a few roses which came from Messrs. A. Robichon and Fils, Orleans, France, and amongst them a new hybrid briar, of which Frau Karl Druschki was said to be one of the parents; but any attempt at taste in arrangement was conspicuous here by its absence, the whole exhibit having a very unfinished appearance.

Quite a pleasing little group of roses, interspersed with acers and ferns, was set up by Messrs. Stuart Low and Co., Bush Hill Park. In this group Ulrich Brunner, with long stems, was in good form, and the same remarks apply to Mrs. John Laing, Mrs. George Shawyer, Frau Karl Druschki, and the Lyon Rose. Varieties of the rambling section were freely employed in the formation of the group.

Weeping standards were the chief feature in the group exhibited by Mr. Charles Turner, of Slough, and amongst them the specimens of Lady Gay, Dorothy Perkins, and Blush Rambler were very well grown. The groundwork underneath was filled up with roses in pots.

Beautiful were the specimen ramblers and weeping standards in the group arranged by Messrs. W. Cutbush and Son, Highgate, and equally beautiful was the bed of dwarf polyantha roses that formed the groundwork.

Name.....

Address.....

Among the varieties were the white Yvonne Barbier, Baby Tausendschon, Mrs. W. Cutbush, Orleans Rose, Jessie, and Maman Turbat.

Novelty was the feature of the rose group exhibited by Messrs. Hobbies, Lim., Dereham. From one point you looked through a pergola of clustering ramblers, chains and posts enclosed the group, and on the tops of the latter cut blooms of roses were arranged. All the specimens were well grown, and the exhibitors are to be congratulated on their break away from the orthodox type of group.

Messrs. George Paul and Son, Cheshunt, made a big display. Weeping standard roses towered up above dwarf specimens, the wichurianas being much in evidence, and the finely flowered plants of Mrs. Aaron Ward, Hugh Dickson, Sunburst, Freda, and Richmond were much admired.

Messrs. George Mount and Sons, Canterbury put up a fine group of roses. The big specimens included White Dorothy, Lady Gay, Dorothy Perkins, and Hiawatha. Of great excellence were the blooms of Mrs. John Laing, Ulrich Brunner, Frau Karl Druschki, Lady Pirrie, Richmond, and Mrs. George Shawyer.

Throughout the whole period of the show crowds of visitors gathered round the display of blooms of Madame Edouard Herriot rose, which was shown in fine colour by Messrs. G. Beckwith and Son, Hoddesdon, who also showed a fine group of Willowmere. M. Hemeray Aubert, Orleans, exhibited plants of the pretty little crimson rose Ponceau.

CARNATIONS.

These formed a charming feature of the exhibition, and their popularity was unquestioned; indeed, they vied with orchids and roses for first place among the subjects staged in the big tent.

A very handsome group, consisting of finely grown Princess of Wales, and Old Blush malmaison varieties, were grouped in little mounds by Mr. W. Jennings, gardener to Leopold de Rothschild, Esq., Ascott, Leighton Buzzard. Between the carnation grouplets Mr. Jennings placed Statice profusa, the whole producing a fine effect.

Messrs. Wm. Cutbush and Son, Highgate, presented a very beautiful exhibit of carnations. Theirs was a circular design with a central mound of flowering plants of the red Lady Coventry, over which was arranged a large vase of a yellow ground fancy variety. Grouplets of Cecilia, Baldwin, Princess of Wales, The Queen, King Arthur, and the crimson Maggie Hodgson formed a lovely groundwork for tall vases of beautiful blooms of R. F. Felton, Lord Rothschild, White Wonder, White Enchantress, Mrs. Lucy Mackinnon, Edna, Marmion, and other leading varieties.

Messrs. Young and Co., Hatherley, Cheltenham, had a squarish group with a bed of moss and ferns. A high columnar stand of the yellow Cecilia occupied the central position, and round it were tall stands of Marmion, Duchess of Devonshire, White Enchantress, Mrs. Brodie Henderson, and Edith Waters. In smaller vases were capital blooms of Rose Enchantress, Rose Doré, Scarlet Glow, Regina, Mikado, Electra, Winsor, Britannia, Hon. Lady Neeld, Mrs. Greswolde Williams, Baroness de Brienen, and May Day. The whole was a most effective contribution, and one could see the grand central column of 200 Cecilias from afar.

Mr. C. Engelmann, Saffron Walden, adapted a novel method in the disposition of his group of carnations, for he made a groundwork of flowers, setting these in low vases on a bed of moss. He filled a large square space, and high in the centre were pyramidal stands with hundreds of blooms of Rosa, Lady Northcliffe, Sunstar, Elektra, White Mrs. Lawson, and White Wonder. My Rose—a lovely rose-pink, the inevitable crimson Carola, the brilliant Beacon, Triumph, Pioneer, and Emperor were varieties set in lower stands and vases, and the whole was a fine effort that further enhanced Mr. Engelmann's reputation.

Messrs. Stuart Low and Co., Enfield, put up a familiar-looking circular group of carnations, and they presented a very pleasing contribution, in which were fine blooms of Triumph, Baroness de Brienen, Fairmount, Empire Day, Princess of Wales, Lady Alington, Mrs. C. F. Raphael, and White Wonder in vases and stands of varying height. The flowers were grouped with ferns, asparagus, and palms. Mr. H. Burnett, Guernsey, had a somewhat small group for him, but he had lovely flowers of Mrs. C. F. Raphael, Beacon, Mikado, Marmion, Mrs. Tatton, White Wonder, etc., staged in tall glass vases.

Particularly effective was the lovely exhibit of carnations set up by Mr. A. F. Dutton, Iver, Bucks. Mr. Dutton filled a triangular space with large baskets of beautiful blooms, and everyone admired this dainty and novel display. Of course, Mrs. A. F. Dutton was finely represented, and so were such excellent varieties as Niagara, Britannia, Winsor, Mikado, Scarlet Glow, Rose Pink Enchantress, Triumph, May Day, and Enchantress. Mr. Dutton is to be heartily congratulated upon the beauty of his blooms and their arrangement.

Mr. S. Mortimer, Farnham, was represented by vases of Carola, Enchantress, Winsor, Victory, and other carnations, with two rows of the sweet-scented All-the-Year-Round stock in front of the vases. The very capital perpetual-flowering pink named Procapital perpetual-flowering pink named Procapital perpetual-flowering pink named Procap

fortnight too early for the bulk of even "May" flowers. In not a few instances the plants shown evinced signs of a degree of forcing that is resented vigorously by hardy flowers, and we are prompted to ask the question whether the best interests of even commercial horticulture are served by exhibiting flowers so far out of season as to mean their appearing altogether out of true characted. This protest refers, of course, to such border plants as should be seen at a July or Augnst show, and does not apply to those subjects that are simply given glass protection to ward off inclement weather. Taken altogether, for all our mild criticism, we readily acknowledge that hardy plants and flowers were very well shown by a large number of well-known growers.

The group of hardy plants and flowers arranged on the ground by Mr. James Box, Lindfield Nurseries, Haywards Heath, was replete with brightly coloured subjects of varied character, suitable for the most part for the general border, whilst in the foreground a choice assortment of primulas, sarracenias, viola species, and other dwarf growing, moisture-loving plants added to the interest of the exhibit. Incarvillea grandiflora was beautifully shown, and the neat yellow heads of Tritoma rufa, and tall spikes of Verbascum Ivanhoe gave relief to the brilliant scarlet geums and Anemone Rouge Ponceau, the latter being as attractive as a Darwin tulip with the addition of elegant foliage. Messrs. T. S. Ware, Lim., Feltham, put up big masses of irises, pæonies, lupins, and trollius, with a foreground of bedding violas in distinct, bright colours. They had also some fine primulas, and a patch or two of epimediums, plants which for beautiful foliage and small but graceful flowers are most useful for shady borders or nooks in the moist parts of a rockery.

Despite the early date, Kelway's delphiniums made a fine show, and an excellent background for the brilliant pæonies and pyrethrums that formed important features of the Langport firm's exhibit. The shimmering white petals of the large-flowered tree Pæony Queen Alexandra stood prominently in front of the group, Elizabeth, a big double flowered variety with rosy-salmon and buff tints, being another variety that pleased us. The delphiniums bore no labels, but blue, mauve, and purple were represented in a wonderful variety of shades.

A circular bed of Viola cornuta purpurea, arranged on the ground by Messrs. Gunn and Sons, Olton, Warwickshire, was a method of arrangement that showed the value of this fine purple flower for big, bold masses. A central mound of the tall white plumes of Saxifraga pyramidalis served to intensify the depth of colour in the violas. The same firm also showed a bed of phloxes, which, in spite of forcing, came out in good colour. Geo. A. Strochlein was specially bright, and Flambeau was also a good salmon-scarlet. Mr. Amos Perry's hardy ferns constituted a distinct feature, and contained many choice and very beautiful varieties of the most useful species. Polystichum angulare frondosum is so broad in frond and regular in division of its fronds as to make it absolutely distinct from most forms of the species, but P. angulare divisilobum laxum is one of fine parts and quite characteristic habit. The various crested forms of Athyriums and Lastreas were all most interesting, and Osmunda gracilis added to the dignity of the group.

The border and rock plants shown by Mr. Perry upheld the reputation of the firm for the excellence and extent of their collection. Lewisia cotyledon, with its pink and white starry flowers, and Viola cornuta Perry's Yellow were small, but choice, subjects, and the varied assortment of Iris germanica, tulips, and pæonies made bold splashes of bright colours. Messrs. G. and A. Clark, Lim., Dover, put up some fine things, such as eremuri, hybrid verbascums, an orange-coloured form of Genm Mrs. Bradshaw, named Mr. J. Bradshaw, and the glowing crimson flowers of Pyrethrum Mrs. Bateman Brown.

Messrs. R. Wallace and Co., Colchester, had a most effective group arranged in three mounds, the central one consisting of choice liliums, among which the pendant mahogany-coloured flowers of L. Dalhansoni, the buff-tinted L. excelsum, and bright yellow L. Hansoni were prominent. L. Marhan and its variety Elien Willmott were other two choice things, and the dwarf, brilliant orange L. tenuifolium Golden Gleam was chaste in the extreme. Early gladioloi, with eremuri, were the feature of one of the side mounds, while astilbes were freely used on the opposite side. Parrot and other tulips, salmon-pink tree pæonies, Primula Veitchi, with whorled umbels of rosy flowers, and a choice variety of violas made up a bright group arranged by Messrs. W. Artindale and Son, Sheffield, and Messrs. George Bunyard and Co., Lim., Maidstone, showed pæonies, lupins, and tulips, as well as miscellaneous border plants. Cytisus incarnatus purpureus was one very distinct and pretty plant of shrubby habit, and the lilac-blue flowers of Pentstemon Menziesi made a good show.

Messrs. Geo. Jackman and Son, Woking, occupied the same position as at the International with a big group of hardy plants, among which Verbascums densiflorum, phœniceum, and Ivanhoe, and the white-flowered Delphinium Moerheimi were spiked flowers of telling aspect. Dodecatheons, double meconopsis, Euphorbia pilosa major, and a colony of Cypripedium pubescens were among the less common subjects of dwarf habit in this interesting group. The massed annuals displayed on either side of a side exit of the tent by Messrs. Watkins and Simpson, Lim., London, showed the decorative value of the best selected strains of clarkias, nemesias, and schizanthus in no indefinite manner, whilst the firm's named antirrhinums once more emphasised the value of these homely flowers for bedding purposes.

Lupinus polyphyllus azurea and Verbascum caledonia on Messrs. G. Gibson and Co.'s stand evidently resented the forcing necessary to bring them out so early, for their colours were somewhat insipid, but the Bedale firm had on their stand some splendid saxifragas, violas, and aubrietias, as well as pink spiræas, dicentras, and white broom.

ALPINE AND KINDRED PLANTS EXHIBITED ON TABLES.

Mr. H. Hemsley, Crawley, built a rockery on staging which he furnished with alpine plants of many kinds. The drooping Onosma Bourgoei, the metallic-hued Sempervivum purpureum, the sombre flowers of Bowles' black viola, and the tiny white Androsace lactea, were a few totally differing but equally interesting little gems that helped to fill his stand. Mr. Hemsley also showed his blue and white forget-me-not named Marie Raphael, and many were the comments this quaint flower drew from the visitors. Mrs. E. Lloyd-Edwards, Bryn Oerog, near Llangollen, brought up her choicest hybrid saxifrages, such as S. sanguinea superba, surely the richest coloured of all, the white-flowered Queen May, and Rose Beauty with clear rosy-pink flowers. Aubrietia Lloyd-Edwards, a quaint yellow-flowered saxifrage, and Wolley Dod's variety of Cheiranthus montanus, were also shown by Mrs. Lloyd-Edwards, who had a painted garden scene as a background to her exhibit.

Polyanthuses and alpine auriculas from Messrs. Storrie and Storrie, Glencarse, Perthshire, were very charming. Messrs. Storrie have succeeded in selecting groups of auriculas that agree in colour so that yellow shades, lavender, and purple, amber and bronze may be had as desired from seed, and the flowers, although not of orthodox form from the florists' point of view, are large and effective for use in the garden. Mr. Howard Crane, Highgate, showed a variety of violas arranged in shallow bowls of sand, there being represented a range of colour extending from pure white through all the colours available in this family.

Mr. James Douglas, Edenside, Great Bookham, showed a collection of auriculas that would have done credit to a National Auricula Show. He had grandly flowered plants of Wm. Smith, a green edge that received an Award of Merit; Mildred Jay, an alpine purple-mauve shaded flower; and the ever good Phyllis Douglas, one of the most attractive of the blue-ground alpines. Prince Charming was a capital green-edge, and Canary Bird a good yellow. Mr. G. W. Miller, Clarkson Nurseries, Wisbech, had selected varieties of daisies, violas, and pyrethrums, his Viola cornuta, purple and mauve varieties, being very attractive. Messrs. Kent and Brydon, Darlington, showed alpine plants on an improvised rockery, and among the subjects displayed were Silene Veseylisti, Veronica chamædrys pedunculata, Aquilegia glandulosa, and Erinus alpinus carmineus. Euonymus radicans Kewensis, a miniature shrub, was very interesting, and the Asperula suberosa was well flowered. The whole exhibit was full of choice and rare things that delight the connoisseur.

Mr. C. H. Herbert's perpetual-flowering pink Progress was as attractive as ever, and he had two or three other varieties, showing possibilities of a range of colours in these continuous-flowering pinks. Sunset, Cottage Maid, Eclipse, and Delicata were the names of four separate and distinct-coloured varieties shown from Acock's Green. Among Messrs. Dobbie and Co.'s pansies we were particularly attracted by Mrs. C. Kay, a deep purple fancy, Sunburst—particularly bright, and Unicorn. Their violas included Edina, a rich navy blue, Redbraes Yellow, Virgin White, and Hector Macdonald, a white-centred blue-banded variety. Mr. Stuart Maples, Stevenage, had a small rockwork exhibit, containing plants of Chrysogonum virginiacum, Oxalis enneaphylla, Myosotis rupicola, and Achillea serbica, besides a number of other useful alpines in suitable arrangement.

Messrs. J. Piper and Sons, Bayswater, showed some choice alpines on a table rockery in the big tent, where we saw Dianthus gloriosus, Æthionema armenum Warley variety, Lychnis Lagascæ, and several primulas in choice assortment. Violas, shown by Mr. W. R. Tranmer, Alma Nurseries, Cottingham, Hull, included Alma—a purple, Maggie Mott, Moseley Perfection, and a number of other varieties that are recognised as the best of their respective colours.

Quite a nice selection of alpines were shown by Messrs. Thompson and Charman, 11, Adam Street, Adelphi, W.C. The very choice Campanula Stepheni nana, and the free-flowering Lewisia Columbiana were easily noticeable, but there were many other very attractive and lovely subjects on this stand.

Mr. Geo. Underwood, Leicester, showed violas in variety, a few among many varieties that we liked being Evelyn Bell, Darkie, General Baden Powell, and Gladys Finlay. A good white cornuta was simply labelled V. cornuta alba, and was very much admired. Primula Cockburniana, P. Veitchi, Achillea tomentosa, and Habranthus pratensis were shown among other things in baskets by Messrs. Whitelegg and Page, Chislehurst.

Novelties in Chinese hardy plants were the feature in Messrs. Bees' stand, brought from Sealand Nurseries, near Liverpool. Roscoea cautilioides, Senecio abrotanifolia, and Dracocephalum bullatum were evry nice. Celmisia spectabilis argentea was a new plant from New Zealand, and Primula vittata, P. Bulleyana, and P. Beesiana were only a few among the many choice Chinese primulas shown. Pedicularis siphonantha, a really unique plant, with charming rosy-cerise flowers and quaint aceæna-like foliage, was undoubtedly one of the best novelties in the show. Enthusiasts were very much interested in the remarkable collection of primulas shown by Dr. MacWatt, Morelands, Duns, Scotland, who, as everyone knows, can show primulas as few people can. Among the rarest were P. deflexa, P. Munroi, P. grandis, and P. Parryi. The whole exhibit was full of novelty and worth, and there was but little in the show of more absorbing interest to those who love and study the primroses of both hemispheres.

Mr. Reg. Prichard, West Moors, Wimborne, showed Campanula Stevensi nana, one of the dwarfest and best of the dwarf campanulas; Helichrysums bellidioides, and Linum capitatum, as well as a variety of alpine plants of quite good quality.

Messrs. Reamsbottom and Co., Geashill, Ireland, had their St. Brigid anemones in a wonderful variety of colour, the blues and mauves and the brilliant scarlets being helped by the whites and paler pink shades. Primula pulverulenta and a hybrid between it and P. Cockburniana called Yarm variety were shown by Mr. W. Laurenson, Yarm-on-Tees. The hybrid is a promising plant of vigorous growth, with fine terra-cotta flowers. Messrs. Phillips and Taylor, Bracknell, Berks, had a group of bog and water plants on one side of the big monument. Primulas pulverulenta Bulleyana and japonica were associated with Trollius Orange Globe and Spiræa Peach Blossom, while gunneras, polygonums, anchusas, etc., made up the principal portions of a good show. Mr. J. Macdonald, Harpenden, made another remarkable display of grass for lawns and golf links. Dried specimens of a great variety of grasses, with botanical names, made a feature of educational value, as also did little patches of growing grasses of varied character grown in soil and on soft, porous felt.

A big crowd gathered round Mr. G. Reuthe's stand, the hardy plants from the Foxhill Nurseries, Keston, embracing a host of charming little rock plants, and quite a collection of Himalayan rhododendrons, which were both graceful in form and of pleasing colours.

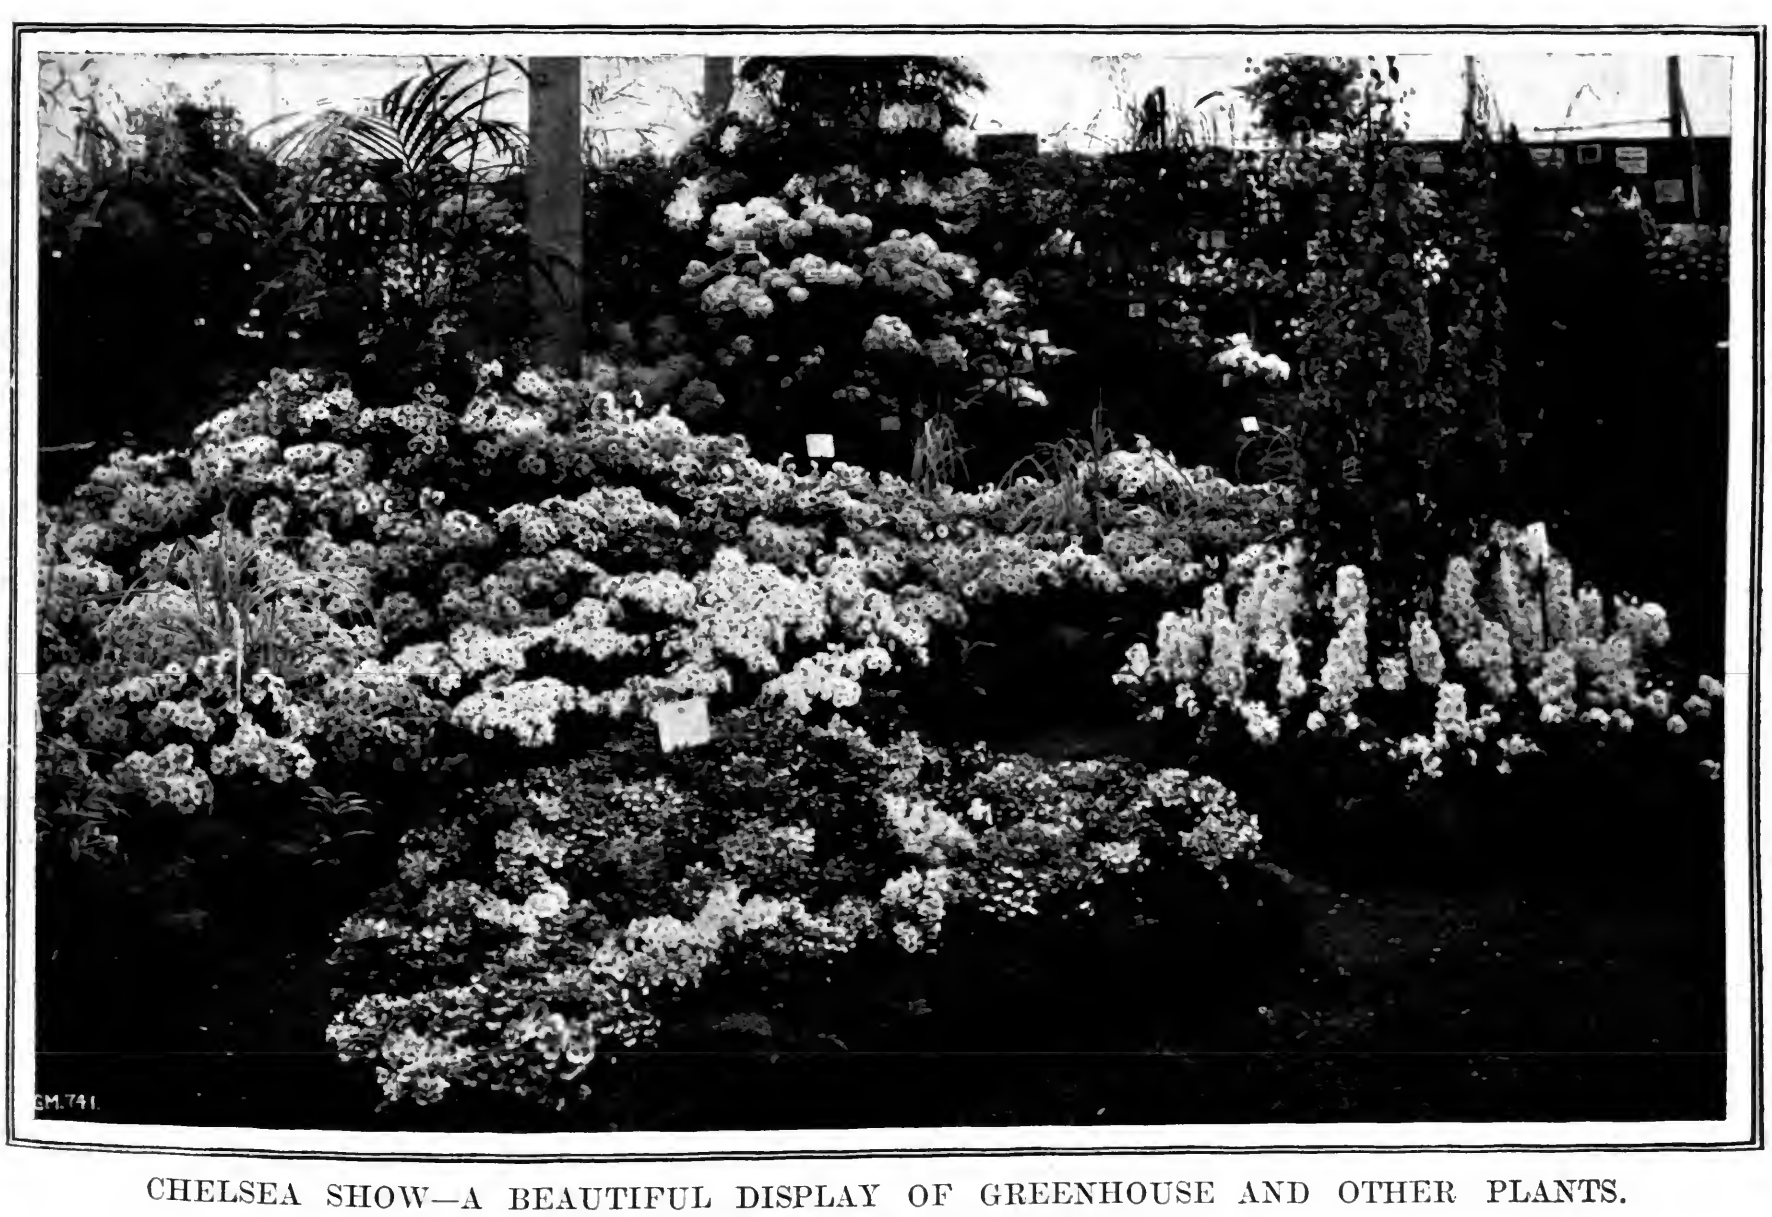
ROCK AND FORMAL GARDENS.

Undoubtedly the rock and formal gardens were, as a whole, finer than in 1912; few were so extensive as last year, but it was evident that many lessons taught by the International Show had been taken to heart, and the rock gardens were more like real rock gardens, and less like mere displays of rocks and alpine plants.

Passing through an iron gate with lions mounted on the pillars on either side, you went by way of a paved walk into an old English garden, arranged by Messrs. Carter and Co. From the low terrace wall a grinning gargoyle spurted water into a semi-circular pool, and the stone-edged borders round about were thickly planted with azaleas and rhododendrons. Little stone men played with dummy cards on a round stone table, or, at least, they were supposed to play, and you mounted the steps to an upper terrace and paved garden. Here a little fountain played under an elm that was permanent, and here again the borders beyond the pavement were furnished with flowers. From the paved garden you looked into a heather-thatched tea house, which looked as old as the armour that hung on the walls. From a leaded window in this structure you looked out over a garden that seemed to belong to a past and gone page in history, where the feminine fashions of modern London seemed somewhat out of place. It was hard to believe that this creation was all the work of the last few weeks.

You hardly could realise that you were in the Chelsea Hospital grounds when you turned a corner and your eyes rested on the weathered Welsh stone which played such an essential part in the rock garden arranged by Messrs. R. Wallace and Co., of Colchester. Away in the distance water tumbled down a rocky cascade into a pool below, and the green turf, dotted here and there with stones, sloped gently to the water edge. Scotch firs at the background seemed to add a still more natural appearance to the cascade, and, while just enough alpine flowers were planted in the crevices between the stones, anything approaching extravagance was studiously avoided. Then, to find contrast, you turned to the left across an expanse of grass and looked over a loose stone wall into a sunk garden, where a kind of stone-built summer-house, covered in with Horescombe tiles from near to Bristol, looked as if it ought to have been in a garden on the Cotswold Hills to have been quite at home. You entered the old English sunk garden by means of stone steps, and wandered round it on a paved footway, admiring the flowers that filled the borders under the shelter of the walls, and you wondered how the pool of water in front of and underneath the stone-built tea house managed to get there. Then, to leave the garden, you mounted other steps, at the top of which there was a stone garden seat, and the figure of a lady supporting an old-world sundial, and then you passed out—and remembered that, after all, you were in the grounds of the Chelsea Hospital. It only remains to be said that Messrs. Wallace's fine effort will be remembered for many a day to come, and we cannot close this all too inadequate description of it without according a word of praise to Messrs. Wallace's expert, Mr. Dillistone, who was responsible for designing these charming gardens.

Messrs. Pulham and Son, 71, Newman Street, Oxford Street, W., had a rock and water garden on an imposing scale, with a neat garden house on the rising ground, from which the whole of the design could be viewed comfortably. A large irregular pool occupied a considerable part of the length of the exhibit, with low rocks rising from the grassy bank on the one side, bolder rocks rising from the other side of the water, then a narrow, rough paved pathway and a steadily rising wall of rocks beyond, with a beautiful little ravine near the summer-house, where a small rocky bridge spanned the rocky watercourse which supplied the pool below. In this cool, shady ravine were ferns and other shade-loving plants. This corner was one of the prettiest of ideas, and was a surprise to all who passed along the pathway to the summer-house. Among the higher rocks were iberis, phloxes, saxifrages, veronicas, cotoneasters, sedums, cytisus, rock cistus, daphnes, etc.; while round the pool we made note of irises, spiræas, bamboos, ferns, trollius, funkias, moisture-loving primulas, etc., with iberis, lithospermums, alyssums, etc., on the rocky mounds. There was something decidedly bold about the scheme of rock garden for which the Guildford Hardy Plant Company was responsible. From the front you looked on a bed of hardy primulas, and surmounting a piece of rockery



CHELSEA SHOW—A BEAUTIFUL DISPLAY OF GREENHOUSE AND OTHER PLANTS.
Arranged by Messrs. Sutton and Sons.

ROYAL SHOW

BRISTOL,
July 1st to 5th, 1913.

74TH ANNUAL EXHIBITION of HORSES, CATTLE, SHEEP, PIGS, POULTRY and FARM PRODUCE; JUMPING, HORSE-SHOEING and BUTTER-MAKING COMPETITIONS, AGRICULTURAL EDUCATION, FORESTRY and HORTICULTURE.

HORTICULTURE
ENTRIES CLOSE MAY 31st
(Live Stock entries close May 20th).

Prize Sheets and Entry Forms will be forwarded on application to

THOMAS McROW, Secretary.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND,
16, Bedford Square, London, W.C.

£600 Cash Prizes. 8 Silver Cups.
THE OPPORTUNITY OF THE YEAR
AT BIRMINGHAM
The Great Midland Show.

On July 18th and 19th. The Royal Horticultural Society and National Hardy Plant Society will send Deputations to make additional Awards.

TAKE SPACE AT BIRMINGHAM.
William C. Carradine, F.R.H.S., Secretary, Birmingham.

WOLVERHAMPTON
GREAT FLORAL FETE,
JULY 8th, 9th, and 10th, 1913.
Over £900 in Prizes.
Schedules on application to the Secretary (post free), R. F. AMPHLETT, 80, Darlington St., Wolverhampton.

GRAND YORKSHIRE FLOWER SHOW AND GALA.
JUNE 18th, 19th, and 20th, 1913.
£800 OFFERED IN PRIZES.
£275 for Orchids, Stove, and Greenhouse Plants.
£175 for Pelargoniums, Carnations, Begonias, etc.
£225 for Roses, Cut Flowers, etc.
£125 for Fruit and Vegetables.
GOLD and SILVER MEDALS for TRADE EXHIBITS.
Entries close 11th JUNE.
For Schedules apply to FRED AREY, Secretary, Davyhall Chambers, York.

HANLEY PARK, STAFFORDSHIRE
JULY 2nd and 3rd, 1913.

SEVENTEENTH
GREAT ANNUAL FLORAL FETE.
£500 in Prizes, Silver Cups, Gold and Silver Medals.
SILVER CHALLENGE CUP, VALUE £10 10s. 0d., OFFERED FOR "TRADE EXHIBIT."
(For particulars see page 7 in Schedule.)
Valuable Special Prizes offered by the Principal Firms in England.
Schedules post free on application to
WM. POULSON,
Secretary.
Town Hall, Hanley.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

beyond were showy-looking geums. Twisting paved walks, with plants growing between the stones, wound in and out amongst the mounds, and at every turn you came across something of special interest. Perhaps amongst the many things that were represented nothing attracted more notice than the little group of the orange-coloured Habranthus pratense.

A diminutive pool with water lily leaves floating on the surface, and surrounded by grey Welsh stone, was the first feature of interest in the rock garden arranged by Messrs. Barr and Sons, London. Beyond this and either sides there were intersecting paths flanked with more rock work and more flowers, and away at the back the garden seemed to lose itself in a woodland glade of bluebells and forget-me-nots. It is hardly necessary to say that the pockets between the stones were furnished with all the gems of the alpine section, with azaleas behind, and anchusas lifting up their blue heads at intervals here and there.

GREENHOUSE PLANTS.

In the centre of the great tent Messrs. Sutton and Sons, Reading, set out a formal flower garden, consisting of a central circular raised bed of very bright and graceful clarkias; Scarlet Beauty shining finely here. Round this were four sets of six beds each, one large and five small ones in each set. These were filled with the firm's specialities, such as stellate and cactus-flowered cinerarias, dwarf nemesias in all brilliant hues, fragrant East Lothian stocks, glorious double begonias, a blaze of colouring; streptocarpus, white, blue, and rose; gorgeously oriental-looking calceolarias, one of which, by reason of its distinctness and beauty, so greatly interested Her Majesty Queen Alexandra that she was graciously pleased to accept a spray of flowers. There were also elegant alonzoas, a glorious lot of rose and white, and mauve Primula obconica, smothered in blooms of fine quality, and one large bed of showy schizanthuses. A little semi-circular bed of large-flowered crimson and white nemesias mixed was one of the prettiest and most striking of the many combinations in this interesting and very effective garden.

The wonderful exhibit from Messrs. Webbs', of Stourbridge, was composed of four huge banks, one consisting of calceolarias, another schizanthuses, and a third cinerarias, and a fourth of begonias and gloxinias. Brilliant in the extreme were the colours shown in the groups, and in front were boxes of green grass, masses of the white Hydrangea Madame Moullière, and Primula obconica gigantea. The brilliancy of the flowers, as a whole, was softened by the interspersal of maidenhair ferns, while a soft green background of muslin added effect. This beautiful display would have been still more effective if the tent roof at this point had been higher. Messrs. Watkins and Simpson, London, set up an interesting display of clarkias, schizanthuses, nemesias, and petunias.

Messrs. Carter and Co., Raynes Park, made up a veritable flower garden in their brilliant exhibit, which filled a large space, and was made up of mounds of stellate and cactus cinerarias, schizanthuses, and others, with masses of gloxinias, white and pink stocks, verbena Miss Willmott, petunias, calceolarias of brilliant colours, florists' cinerarias, salvias, and other things, with miniature lawns of the greenest grass dotted about in between, margined with white streptocarpus. The whole scheme of the exhibit was novel and original, the arrangement of the plants left no room for criticism, while good cultivation was the hall mark of every plant represented. A very fine collection of amaryllis was shown by Messrs. Robert P. Ker and Sons, Aigburth Nursery, Liverpool. Many of the colours represented were very beautiful, and amongst the varieties that attracted attention were Magnificent, The Queen, White Lady, Pink Beauty, Monarch, and Scarlet Gem. The flower stems were short and sturdy, and the plants were pleasingly arranged over a groundwork of maidenhair fern.

MEDALS AND AWARDS.

Gold Medals. — To Sir George Holford, K.C.V.O., C.I.E., Westonbirt, Tetbury, for orchids; to Messrs. Charlesworth and Co., Haywards Heath, for orchids; to Messrs. Sander and Sons, St. Albans, for orchids; to Messrs. R. Wallace and Co., Colchester, for rock and formal garden; to Mr. J. Wood, Boston Spa, for rock garden; to Messrs. Jas. Carter and Co., Raynes Park, for flowering plants and vegetables; to Messrs. J. Veitch and Sons, Chelsea, for trained fruit trees, for stove and greenhouse plants, and for flowering shrubs, etc.; to Messrs. Sutton and Sons, Reading, for flowering plants; to Messrs. R. L. Russell, Richmond, for stove plants, ivies, and shrubs; to Messrs. Blackmore and Langdon, Bath, for begonias, etc.; to Messrs. Frank Cant and Co., Colchester, for roses; to Messrs. R. and G. Cuthbert, Highgate, for azaleas; to Messrs. Dobbie and Co., Edinburgh, for sweet peas, etc.; to Mr. C. Englemann, Saffron Walden, for carnations; to Messrs. W. Paul and Sons, Waltham Cross, for roses and flowering plants; to Messrs. J. Piper and Sons, Bayswater, for shrubs, etc.; to Messrs. J. Waterer and Sons, Bagshot, for flowering plants; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Messrs. Alex. Dickson and Sons, Newtownards, for tulips; to Hon. Vicary Gibbs, Elstree, for vegetables; to Messrs. W. Fromow and Sons, Chiswick, for Japanese maples; to Messrs. T. Rivers and Son, Sawbridgeworth, for fruit trees and citrus fruits in pots; and to Messrs. W. Cutbush and Son, Highgate Nurseries, for carnations.

Farrer Cup.—To Messrs. Bees, Lim., Liverpool, for rare alpines.

Davidson Cup.—To Messrs. Charlesworth and Co., Haywards Heath, for the best cattleya, not a hybrid, in the show (C. Percivaliana var. Mary Regina).

R.H.S. Silver-Gilt Cups. — To Messrs. J. Backhouse and Son, Lim., York, for rock and water garden; to Messrs. Barr and Sons, Covent Garden, for rock and water garden; to Messrs. J. Piper and Son, Bayswater, W., for rock and water garden; to Messrs. J. Veitch and Sons, Chelsea, for tulips and general exhibits; to Messrs. Jackman and Son, Woking, for clematises, shrubs, and plants; and to Messrs. G. Bunyard and Co., Maidstone, for apples.

R.H.S. Large Silver Cups.—To Mr. Maurice Prichard, Christchurch, for alpine, garden, and herbaceous plants; to Messrs. Sutton and Sons, Reading, for vegetables, etc.; to Mr. L. R. Russell, Richmond, for foliage and flowering plants; to Messrs. Paul and Sons, Cheshunt, for roses and azaleas; to Mr. Charles Turner, Slough for roses, carnations, lilacs, etc.; to Messrs. E. Webb and Sons, Stourbridge, for calceolarias and flowering plants; to Messrs. Young and Co., Cheltenham, for carnations; and to Mr. Amos Perry, Enfield, for herbaceous and alpines.

R.H.S. Silver Cups.—To Sir Jeremiah Colman, Bart., Gatton Park, Reigate, for orchids; to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Stuart Low and Co., Bush Hill Park, for orchids; to Messrs. J. and A. McBean, Cooksbridge, for orchids; to Messrs. Pulham and Son, Newman Street, for rock garden; to T. S. Ware, Lim., Feltham, for rock garden; to Messrs. J. Cheal and Sons, Crawley, for formal garden, alpines, and shrubs; to Messrs. Jas. Carter and Co., High Holborn, for formal garden; to Hon. Vicary Gibbs, Elstree, for pelargoniums; to Miss Troyte-Bullock, Yeovil, for pelargoniums; to Leopold de Rothschild, Esq., C.V.O., Leighton Buzzard, for carnations and statice; to Messrs. W. Cutbush and Son, Highgate, for flowering plants, etc.; to Messrs. Ben Cant and Sons, Colchester, for roses; to Messrs. J. Hill and Son, Lower Edmonton, for ferns; to Hobbies, Lim., Dereham, for roses; to Mr. J. MacDonald, Harpenden, for grasses; and to Messrs. G. Mount and Sons, Canterbury, for roses.

R.H.S. Standard Cup.—To E. H. Davidson, Esq., Borlases, Twyford, for orchids; to Messrs. Mansell and Hatcher, Rawdon, for orchids; to the Craven Nursery Company, Clapham, Yorks, for rock garden; to Messrs. Cunningham, Fraser, and Co., Edinburgh, for alpine plants; to Mr. Clarence Elliott, Six Hills Nursery, Stevenage, for rock garden; to Mr. G. Reuthe, Keston, for rock garden and herbaceous plants; to Messrs. Whitelegg and Page, Chislehurst, for rock garden and alpines; to Messrs. G. Beckwith and Sons, Hoddesdon, for roses; to Mrs. B. Barrett, Castlethorpe, for schizanthus; to Mr. A. J. Bruce, Chorlton-cum-Hardy, for sarracenias; to Miss Litkie, Garden, near Hulbert, Duns, for primulas; to Mr. Reginald Prichard, Wimborne, for alpines; and to Mr. Geo. Prince, Longworth, for roses.

Silver-gilt Hogg Medal. — To Messrs.

Laxton Bros., Bedford, for strawberries and fruit trees.

Silver-gilt Knightian Medal.—To the King's Acre Nurseries, Hereford, for fruit trees.

Silver-gilt Flora Medal.—To Messrs. Hascall and Co., Southgate, for orchids; to Messrs. Barr and Son, Covent Garden, for tulips, etc.; to Messrs. Stuart Low, Bush Hill Park, for carnations, etc.; to Messrs. Phillips and Taylor, Bracknell, for herbaceous, etc.; to Messrs. Hogg and Robertson, Dublin, for tulips, etc.; to Mr. Bell, Guernsey, for carnations; to Mr. J. Box, Lindfield, for hardy plants; to Mr. Burnett, Guernsey, for carnations; to Messrs. G. and A. Clark, Dover, for hardy plants; to Messrs. Jefferies and Son, Cirencester, for tulips; to Messrs. T. S. Ware, Feltham, for herbaceous plants, etc.

Silver-gilt Banksian Medal.—To the Guildford Hardy Plant Nursery, Guildford, for rock garden; to Messrs. Artindale and Son, Sheffield, for hardy and water plants; to Messrs. Allwood Bros., Haywards Heath, for carnations; to Messrs. Artindale and Son, Sheffield, for hardy and water plants; to Messrs. Bakers, Wolverhampton, for hardy alpine and bog plants; to Messrs. Fletcher and Son, Chertsey, for American plants; to Messrs. Gibson and Sons, Bedale, for herbaceous plants; to Messrs. Kelway and Son, Langport, for herbaceous; to Messrs. Ker and Sons, Liverpool, for amaryllis; to Mr. A. Needham, Kelmscott, for tulips; to Mr. R. C. Notcutt, Woodbridge, for flowering and foliage plants; to Messrs. Watkins and Simpson, Covent Garden, for annuals in pots.

Silver Knightian Medal.—To the Thatcham Fruit Farm, Newbury, for vegetables.

Silver Flora Medal.—To Mr. S. W. Flory, Twickenham, for orchids; to the Burton Hardy Plant Company, Christchurch, for rock garden; to Messrs. R. H. Bath, Wisbech, for tulips and carnations; to Mr. C. Blick, Hayes, for carnations; to Mr. C. Bourne, Bletchley, for tulips; to A. P. Brandt, Esq., Bletchingley, for fancy pelargoniums; to Messrs. H. Cannell and Sons, Swanley, for cannas, pelargoniums, etc.; to Messrs. Carter Page and Co., London Wall, for herbaceous; to Mr. J. Douglas, Great Bookham, for carnations; to Mrs. Edwards, Llangollen, for alpines; to Messrs. Godfrey and Son, Exmouth, for pelargoniums, etc.; to Messrs. Gunn and Sons, Olton, for herbaceous; to Mr. A. Hemsley, Crawley, for alpines; to the Misses Hopkins, Shepperton, for herbaceous; to Messrs. E. W. King and Co., Coggeshall, for sweet peas; to Rev. H. Buckston, Hutton Hall, for calceolarias; to Mrs. Rolls Hoare, Horsham, for scented pelargoniums; to Robert Sydenham Limited, Birmingham, for sweet peas; to Messrs. Thomson and Charman, Adelphi, for hardy plants; to Messrs. Robt. Veitch and Son, Exeter, for calceolarias; to the Wargrave Plant Farm, Liverpool Street, E.C., for tulips, herbaceous, etc.; and to Mr. Carlton White, Bond Street, for clipped box and topiary work.

Silver Banksian Medal.—To Mr. H. Dixon, Wandsworth, for orchids; to Mr. C. F. Waters, Balcombe, for orchids; to Messrs. R. Tucker and Sons, Oxford, for rock garden; to Messrs. A. J. and C. Allen, Norwich, for roses; to Mr. E. C. Bowell, Cheltenham, for alpines; to Mr. H. H. Crane, Highgate, for violas; to Messrs. John Forbes, Lim., Howick, for herbaceous plants; to Mr. H. J. Jones, Lewisham, for pelargoniums; to Messrs. Kent and Brydon, Darlington, for flowering plants; to Messrs. B. Ladhams, Lim., Shirley, for hardy plants; to Mr. W. Lawrenson, Yarm-on-Tees, for primulas; to Mr. W. A. Manda, St. Albans, for foliage and plants; to Mr. G. W. Miller, Wisbech, for herbaceous; to Mrs. S. Mortimer, Farnham, for stocks and carnations; to Messrs. Reamsbottom and Co., Geashill, for anemones; to Messrs. W. H. Rogers and Son Lim., Bassett, for alpines, etc.; to Mr. J. D. Webster, Chichester, for carnations; and to Messrs. W. Wells and Co., Merstham, for carnations.

Bronze Medal.—To Messrs. Barrie and Brown, 39, King William Street, E.C., for herbaceous plants; to Messrs. W. and J. Brown, Peterborough, for lilacs, roses, etc.; to Mr. T. E. Dawes, Syderstone, for rhubarb; to Mr. R. d'Enncourt Day, Sutton Scolney, for Spanish iris; to Mr. H. N. Ellison, West Bromwich, for ferns and palms; to Mr. Stuart Maples, Stevenage, for alpines.

AWARDS TO HORTICULTURAL SUNDRIES.

Silver-Gilt Flora Medal.—To Mrs. Edith Fisher, E. Molesey, for water-colour drawings of gardens.

Silver-gilt Banksian Medal.—To Messrs. J. Carter and Co., Raynes Park, S.W., for seed-testing experiments; to Castles' Shipbreaking Co., Lim., Millbank, S.W., for garden furniture; to Messrs. Drew, Clark, and Co., Leyton, for diamond extension ladders; to Messrs. Sutton and Sons, Reading, for botanical and scientific exhibits; to Messrs. Wood and Sons, Wood Green, N., for pergola, garden houses, etc.

Silver Banksian Medal.—To Messrs. Pulham, 71, Newman Street, W., for garden furniture; to Messrs. G. and W. Purser, Lim., Hatton Garden, E.C., for spraying appliance; to Messrs. D. Roberts and Son, Tottenham, N., for tubs for shrubs; to Messrs. Wm. Duncan Tucker and Sons, 27, Cannon Street, for greenhouses, etc.; to the United Brass Founders and Engineers Co., Manchester, for spraying machines; to Messrs. Watkins and McCombie, 19, Paternoster Row, E.C., for horticultural illustrations; to Messrs. J. P. White and Sons, Lim., Pyghtle Works, Bedford, for garden furniture; to Miss Edith H. Adie, 9, Brechen Place, S.W., for oil paintings of garden subjects; to the Four Oaks Spraying Machine Co., Sutton Coldfield, for Knapsack sprayers; to Messrs. Green and Nephew, Lim., 107, Queen Victoria Street, E.C., for flower glasses; to Messrs. Headley Bros., 13, Devonshire Street, Bishopsgate, E.C., for garden books and pictures; to the Potter's Art Guild, Compton, Guildford, for terra-cotta garden furniture; to Messrs. R. Wallace and Co., Colchester, for plans of new gardens; to the Acme Patent Ladder Co., Earlsfield, for ladders, steps, etc.; to Messrs. Benton and Stone, Lim., Birmingham, for syringes, etc.; to Messrs. T. Crowther and Sons, Fulham, for iron gates, vases, etc.; to the Dryad Works, Leicester, for Dryad cane furniture; to the En Tout Cas Co., Lim., Syston, Leicester, for garden seats and trelliswork; to Messrs. A. W. Gamage, Lim., Holborn, London, for garden houses, chairs, etc.; to Messrs. H. Hartjen and Co., Noble Street, E.C., for spraying machines; to Messrs. J. H. Heathman and Co., Parsons Green, S.W., for various ladders, engines, etc.; to Messrs. Bolckow, Hughes, and Co., Blyth, for teak wood garden furniture; to Messrs. Charles P. Kinnell, 65, Southwark Street, S.E., for boilers; to Messrs. Liberty and Co., Regent Street, W.; for garden furniture; to Messrs. Maggs and Co., Queen's Road, Bristol, for teak wood garden seats; to the Patent Safety Ladder Co., Peterborough, for extension ladders.

Bronze Banksian Medal.—To the Leyton Timber Co., Lim., Deptford, for rustic garden furniture; to the London Provincial and Export Co., Wandsworth, S.W., for garden furniture; to Messrs. Thos. Sayer and Co., 45, Wilson Street, E.C., for garden furniture; to Messrs. Vipan and Headley, Leicester, for garden seats, etc.; to the Selborne Society, Hanwell, W., for bird nesting boxes; to Messrs. Barr and Sons, Covent Garden, for garden requisites; to Messrs. Blake and Mackenzie, Liverpool, for flower pots and seed testers; to Mr. Robert Hughes, Potter's Bar, for water-colour drawings of gardens; to Mr. J. Pinches, Camberwell, S.E., for horticultural (acme) labels; to Robert Sydenham Limited, Birmingham, for rustic table decorations; to Messrs. Cooper, Pegler, and Co., Christopher Street, E.C., for spraying machines; to the Economic Fencing Co., Billiter House, E.C., for wood fencing and trelliswork; to Messrs. Fenlon and Son, 8, Tudor Street, E.C., for new hotwater boilers; to the Hardy Patent Pick Co., Sheffield, for garden forks, spades, etc.

ORCHID COMMITTEE AWARDS.

First-class Certificate. — To Cattleya Empress Frederick alba, from Messrs. Mansell and Hatcher, Rawdon, Leeds; to Odontioda Chanticleer Orchidhurst var., from Messrs. Armstrong and Brown, Tunbridge Wells; to Lælio-cattleya Britannia Westonbirt var., from Lieut.-Colonel Sir George Holford, Tetbury, Gloucester; to Lælio-cattleya Sylvia, Princess Victoria Louise, from Messrs. Charlesworth and Co., Haywards Heath; to Miltonia Charlesworthi, from Messrs. Charlesworth and Co., Haywards Heath; to Lælio-cattleya Fredk. Boyle, Gatton var., from Sir Jeremiah Colman, Reigate; to Odontoglossum Queen of Gatton, from Sir Jeremiah Colman, Reigate; and to Odontoglossum Othmarschem, from Baron Bruno Schröder, Englefield Green.

Award of Merit.—To Odontoglossum eximium Armstrongæ, to Brasso-cattleya Excelsior, and to Lælio-cattleya Aphrodite splendens, from Messrs. Armstrong and Brown, Tunbridge Wells; to Oncidium McBeanianum, to Cattleya Mendeli May Queen, to Odontioda Charlesworthi Perfection, and to Cymbidium Gottianum superbum, from Messrs. J. and A. A. McBean, Cooksbridge; to Lælio-cattleya Ganymede, Holford var., from Lieut.-Colonel Sir G. Holford, Tetbury, Glos.; to Odontoglossum illustrissimum Westonbirt var., from Lieut.-Colonel Sir G. Holford, Tetbury, Glos.; to Odontioda Chelseaensis var. St. Fuscien, from Mons. Graire, Amiens, France; to Odontoglossum Georgius Rex, from Messrs. Charlesworth, Haywards Heath; to Brasso-cattleya Vilmoriniana, var. Etna, from Messrs. Sander and Sons, St. Albans; to Odontonia Lælia Sander, from Messrs. Sander and Sons, St. Albans; to Oncidioda Cooksoniæ var. illustris, from Messrs. Sander and Sons, St. Albans.

Cultural Commendation.—To Sobralia macrantha alba, from J. Gurney Fowler, Esq., Woodford; to Miltonia vexillaria virginale, and to Miltonia vexillaria Snowflake, from Lieut.-Colonel Sir G. Holford, Tetbury, Glos.; and to Cattleya Mossiæ Mahomet, also from Westonbirt.

FLORAL COMMITTEE AWARDS.

First-class Certificate. — To Nephrolepis exaltata Willmottæ, from Messrs. H. B. May and Sons; to Cupressus Lawsoniana Fletcheri, from Messrs. Fletcher; to Meconopsis Delavayi, from the Edinburgh Botanical Gardens.

Botanical Certificate.—To Olearia Chathamica, from the Rev. A. T. Boscawen.

Award of Merit.—To Campanula Stevensi nana, from Mr. R. Prichard; to Pentstemon Davidsoni, from Mr. C. Elliott; to Auricula William Smith, from Mr. J. Douglas; to Calceolaria Clarefield Gem, from Mrs. Litkie; to Rose Nancy Perkins, from Mr. Perkins; to Rose Irish Fireflame, from Messrs. Alex. Dickson and Sons; to Rose Mrs. Campbell Hall, from Messrs. Alex. Dickson and Sons; to Saxifraga Grandfieldi, from Sir Everard Hambro; to Begonia Lena, from Messrs. Blackmore and Langdon; to Roscoea cautilioides, from Messrs. Bees, Lim.; to Rose White Tausendschon, from Messrs. Wm. Paul and Son; to Sarracenia Brucei, from Mr. A. J. Bruce; to Aster Falconeri, from Messrs. Barr and Sons; to Cytisus Andreana prostrata, from Mr. L. R. Russell; to Styrax Wilsoni, from Miss Willmott, V.M.H.; and to Lonicera tragophylla, from Messrs. J. Veitch and Sons.

*** The sections devoted to trees and shrubs, stove and greenhouse plants, tulips, sweet peas, fruits and vegetables, and sundries, are unavoidably left over, as also is a portion of the Rock and Formal Gardens section, until our next issue (May 31), which will also contain descriptions, with illustrations, of the new plants.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

THE COOL HOUSE.—The various species and hybrids of the odontoglossums are now giving a fine display of bloom. The dull weather which has been prevalent has prolonged the freshness of the flowers, but, on the other hand, it has checked plants in an advanced state of bud development expanding their flowers. I have previously pointed out the injury likely to be caused by keeping the flower spikes two long on the plants, and I will only mention that the fact of the flowers retaining their beauty for a longer period does not lessen the liability of the plants to suffer from the strain caused by flowering. With a continuance of the present conditions outside, no doubt many exhibitors will find considerable difficulty in having their plants in full bloom in time for the summer shows, and where plants are required it is best to give them a little warmer conditions to assist them to expand a few days before they are required. It is advisable that all cool orchids that have been treated in this manner should have the cool house treatment two or three days before they are required for use. This enables them to regain any loss of vigour caused by the warmer treament.

ONCIDIUM MACRANTHUM.—There is no oncidium more worthy of cultivation than O. macranthum, for it is most tractable grown in the cool house, and does well under the same conditions as are suited to Odontoglossum crispum; that is to say, a temperature ranging from 50 to 55 deg. normal winter conditions, with about 55 to 58 deg. in summer. The greatest difficulty will be found in keeping the house at the summer temperature mentioned, but every effort should be made to do so. The temperature of the cool house is not so great a consideration to its occupants as obtaining the suitable conditions of the atmosphere. A pure but practically saturated atmosphere is essential. The plants are in practically an active state of growth at all seasons of the year, and therefore require liberal root moisture, and thus annual repotting is desirable. This is best done when the new roots make their appearance, from the base of the newly-developing growth. We find they require liberal pot-room. The pots used should be well drained, and a fairly open compost with a liberal amount of sphagnum meets their requirements; this is made firm about the roots and base of the plants. The flowers are usually produced during the late spring and summer months. The long rambling spikes are best trained by having four neat stakes placed at even distances around the edges of the pot, so that the flower scape may be displayed to the best advantage after they expand. There are no orchids more serviceable for exhibition than O. macranthrum in a high state of development, or for general decorative effect. —H. J. Chapman, Oakwood Gardens.

STOVE PLANTS.

ACHIMENES that are growing freely and rapidly approaching the flowering stage will benefit by an occasional application of plant food and soot water. Allow plenty of room between the pots, and neatly stake and tie the individual plants. Grown in baskets they are very pleasing, if in the process of planting the corms have been so placed that some must grow through the moss at the sides, these being allowed to hang naturally, while the growth of the others are carefully tied out. As the flowers develop the plants may be removed to a somewhat cooler temperature, and every effort made to prolong the flowering season.

NEPENTHES.—These interesting stove plants are seen at their best when growing in baskets. It is not advisable to unnecessarily disturb them at the roots, but when a shift is required the present is a suitable time for their receiving it. They grow well in a mixture of Osmunda fibre or coarse orchid peat, sphagnum moss, and well broken charcoal. Carefully make this material firm about the roots, which must not be damaged, with the fingers, or by the aid of a dibber. sever when roots have formed, and pot up basket will derive benefit from having the spent surface compost removed and replaced by a top-dressing of new material. Subsequently they will require a humid atmosphere, to be shaded from sunshine, and when growing freely plenty of water. Propagation may be effected by cuttings, or, better still, by half-severing the stem under a joint, binding round a little of the compost within a handful of moss. Completely sever when roots have formed, and pot up or put in baskets, and keep the young plants very close until they are established.

BEGONIA GLOIRE DE LORRAINE.—This begonia is also adapted to basket culture. Prepare wire baskets by lining them with fresh green moss and filling with a compost of fibrous loam two parts, peat and leaf-mould one part each, a little dried cow dung, and sufficient sand to keep the compost open. The earlier rooted plants may now be used in filling the baskets. Turn them out of their pots and place several round the sides and one in the centre, the number to be used depending upon the size of the basket. Plant fairly firm, leaving sufficient space at the top for watering, it not being always convenient to remove the basket for dipping. Give a start in the stove, afterwards, if desired, they may be suspended from the roof of a cooler house. Those to be grown in pots should be shifted on as becomes necessary. Plants to be grown in small pots for late flowering may now be raised from cuttings.

OTHER BASKET PLANTS.—Among the other stove plants that may be grown in baskets are Asparagus Sprengeri and decumbens, and several of the crested and plumose varieties of nephrolepis, including Amerpohli, Marshalli, and todeaoides. Planted firmly in a similar compost to that above recommended, in baskets lined with moss, they are not only useful in decorations, but also provide quantities of foliage for associating with cut flowers.

VENTILATING AND FIRING.—In bright, warm weather ventilate early and fairly freely in the daytime; a little air may also be admitted with advantage on mild nights. Dispense as far as possible with fire-heat, checking the fires early in the morning in bright weather, and avoiding the too free use of them at night, always, however, being prepared for the dull or wet day and cold night.—H. Prime, Hatfield House Gardens.

THE FLOWER GARDEN.

SUMMER BEDDING.—This important work can now be proceeded with safely, excepting in the northern and cold exposed districts, where a commencement is usually deferred until the end of the month. In the general way a somewhat definite idea is formed at the end of the previous season as to the arrangement of the beds in the following year, and stocks of the various subjects which will be required are worked up. Variation in the schemes from year to year increases the attractiveness of summer bedding when tastefully carried out, and this should not be a difficult matter with the many beautiful plants available. When due thought and attention have been given in this respect, transferring the plants to their summer quarters is very much simplified, and can be executed in a methodical manner, saving much time and worry. The beds will, as a general rule, have been occupied by spring flowers, some of which impoverish the soil considerably, and steps must be taken to enrich the soil. On the other hand, many require well-decayed manure; this must be done with due consideration of the requirements of the kinds that are to occupy the different positions. Planting some kinds in ground that has been liberally manured would produce disappointing results, especially in the case of pelargoniums, and some plants grown for their brilliantly-coloured leaves: these are usually seen to their best advantage in poor soil. On the other hand, many require well-manured soil, among them being begonias, fuchsias, heliotropiums, stocks, asters, and nicotianas. Large specimen plants grown as pyramid and standard form enter largely into most bedding arrangements of the present day. These, on being transferred to the open, are most liable to damage from winds, and as planting proceeds, each one must be securely staked and tied. This takes up much time at such a busy period, but it must not be neglected.

DAHLIAS.—In most gardens dahlias form a distinct feature and have quarters allotted to them. When such is the case the ground has been well dug and manured, and so needs but little preparation at the present time. It will, in fact, be only necessary to move the surface, and work it down to receive the plants. They make useful additions to herbaceous borders, and are often used in an effective manner; their freshness is very appreciable when many of the other inhabitants are beginning to die down, and with their wide range of colours it is possible to so arrange them as not to be obtrusive in any colour scheme. When used in this manner it is a good practice to work in plenty of rotten manure when preparing the sites, and also to use some fresh soil to work round the roots when planting.

TERRACE SPECIMENS. — Agapanthus, myrtles, etc., growing in vases and tubs for furnishing terraces are now growing very freely, and should be very liberally supplied with water and applications of artificial and liquid manure. These subjects readily respond to good treatment.—T. B. Field, Wych Cross Place Gardens.

Dalechampia Roezliana.—When it was first introduced in 1867, this dalechampia was spoken of as a rival to the poinsettia, to which indeed it is nearly allied. In both of them the showiest portion of the inflorescence is not the flowers themselves, but the bracts which subtend them. This dalechampia forms a plant of rather upright growth, and the flowers are borne on the upper part. The floral leaves or bracts are of a bright rosy-pink colour, a decidedly pleasing tint. There is a variety (alba) with white bracts. Seeds often ripen from which young plants can be readily raised, while cuttings also strike without difficulty.—K.

NOTICE.

READERS experiencing difficulty in obtaining "THE GARDENERS' MAGAZINE" at any bookstall or newsagent should write to the

PUBLISHING MANAGER,
148-9, Aldersgate Street,
London, E.C.,

who will give the matter immediate attention.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

PROPAGATION OF THE COMMON BROOM.—P. E. W., Beaulieu: Will you please tell me how to propagate the Common Broom?—The Common Broom may be readily increased by means of seeds sown thinly in drills in the open ground. The seeds ripen freely, and should be sown as soon as ripe; seedlings should be transplanted in spring. It is also possible to increase stock by layering, or by making cuttings of flowerless shoots during August or early September, placing these in fine sandy soil, in a cold frame or under a hand-light in a shady position. The varietal forms, such as Andreanus, pendulus and sulphureus, must be increased by cuttings if they are to be kept true, or be grafted upon the type form.

ORIGIN OF THE GHENT FLOWER SHOWS.—A. P., Bristol: I have been very greatly interested in your descriptive and illustrated account of the recent great show at Ghent, the more so because, passing through Belginm while it was held, I called at Ghent and saw the exhibition. I congratulate you upon the promptness with which you presented the account of this wonderful display, but I should be greatly obliged if you will tell me, briefly, through your columns, how the Ghent shows originated.—About the year 1622 Bishop Triest, long known for his love of flowers and art, formed a brotherhood of gardeners at Ghent, with St. Amand and Ste. Dorothee as the patron saints. In addition, a society of amateurs was founded at Ghent in 1669 by Abbot Reyntkens, who was devoted to horticulture, and wrote a book thereon, which was published in 1675. These two fraternities did excellent work in the encouragement of horticulture, but, as in the case of all the other organisations, they were suppressed by the decree of August 18, 1792. But the number of gardeners in the employment of the large landed proprietors and the wealthy amateurs rapidly increased, and little by little commercial cultivators, half florists and half market gardeners, became established about Ghent. It was chiefly along the Conpure that the establishments of the latter were met with. Even after the great changes in this part of Ghent the horticultural establishments remained. At the commencement of the 19th century there was, on the right-hand side of the river, and at the point where the passage of the Conpure joined the paved roadway, a public-house, bearing the sign, "In Frascati." It was occupied by a gardener, and his fellow gardeners, of whom there were considerable numbers in the neighbourhood, were the principal customers. A goodly number of amateurs also visited the house for the purpose of meeting those having tastes similar to their own. It was at one of the meetings at this inn that the Société Royale d'Agriculture et de Botanique had its origin. On October 10, 1808, Frans Van Cassel, who had returned from England a short time previously, described to his friends what he had seen in England, and he proposed that a society should be formed at Ghent for the purpose of organising exhibitions of flowers, etc., with a view to assist the development of commercial horticulture and a love for flowers in the city. The proposition was received with enthusiasm, and at a subsequent meeting Avocat Lebèque, one of the principal judges and a distinguished amateur horticulturist, was requested to prepare the rules. Of the forty-seven persons who assisted at the foundation of the society, eighteen were gardeners, and the other founders included architects, doctors, lawyers, hosiers, plumbers, painters, and a police commissioner. To render the exhibition interesting and useful, each member was required to send two pots containing plants, flowers, or shrubs, or pay a small fine. Members could send more than two pots, but not more than six. The arrangement of the exhibition was made by five specially appointed commissaires, and the members had to accept without murmur the position in which their plants were placed, or pay a fine. In carrying out its programme the society held its first exhibition at "In Frascati," February 6, 1809. This proved most gratifying to the promoters, and the subsequent shows were so successful that in 1815 it was found necessary to provide more room for them. It was then arranged to hold them in the garden of "In de Zaal Flora," a public-house in the Rue de la Caverm, and a spacious building was specially erected for the purposes of the shows. Three years later the King evinced a warm sympathy with the objects of the society, and the committee asked him to permit them to add Royale to the title, and grant them a coat of arms, and he at once granted the requests. The coat of arms was composed of a watering-pot, spade, rake, and other gardening tools, with the motto, "Veneficia mea. Quirites; haec, sunt." Since then the society has made great progress, and for many years it held its exhibitions at the Town Hall, and then at the Casino where it made its home. Now it has the huge building in which the recent quinquennial exhibition was held.

GERMINATION OF MUSTARD AND CRESS.—A. H., Newcastle: Will you kindly let me know the shortest possible time in which mustard and cress can be secured ready for use from the time of sowing. Of course, I am aware different temperatures give different results. This may seem a rather silly question, but I have been told

The Alpha No. 3 obtained First Award for Hand Sprayer at the R.H.S. Trials, Wisley, April 23rd, 1913.

The finest Garden Sprayer in the World.

As used in Windsor Castle Gardens.

It is proof of the superiority of the Alpha that it has the approval of the Royal Gardeners, and is used throughout the gardens of Windsor Castle. It also bears the hall mark of quality conveyed in the expressed satisfaction of the Royal Horticultural Society, who regard it as being one of the simplest and best machines they have ever tested. During last year many thousands of these handy little machines were sold for many different purposes, to which they admirably suit, but by far the greater quantity were sold into the gardens of this and other countries, where they are giving the most efficient service.

ALPHA SPRAYER,

No. 3, 3-Quarts Capacity, Price 17/6

is an important item in every well-equipped garden. It is always ready to be charged for any spraying purpose, with thick or thin fluid, either of which it distributes with force and fineness. The Alpha is the simplest possible machine. It has not an attached pump, either internal or external. The air which provides the distributive energy is compressed in the machine by means of an ordinary cycle foot-pump, attached to and detached from the machine exactly as to a cycle tyre. The all-steel body is protected internally against the corrosive action of chemicals by a lining of lead, further reinforced by a coating of bitumen mastic.

YOUR SEEDSMAN

either has Alphas in stock to supply your immediate requirements, or can get an Alpha for you in 24 hours, therefore insist on the Alpha and refuse imitations.

AWARDED 18 GOLD AND SILVER MEDALS.

Send for the Alpha List if you want a larger machine. Alphas are made in varying capacities up to 40 gallons and more, and also ask for the new Carmona Plant Food Book on plant feeding, and Set of Art Post Cards.

Address requests to—

ROBINSON BROTHERS Ltd.,

Manufacturers of Guaranteed Gardenalities,

:: :: WEST BROMWICH. :: ::

that my predecessor could have mustard and cress ready thirty-six hours after sowing; if there is an express method I should like to know about it.—We do not know what is the shortest possible time in which mustard and cress can be had fit for use after sowing, but, given suitable conditions, and a thorough soaking of the seeds in warm water previously, so that they are just about to germinate when spread upon moist, warm flannel or felt stretched over a box of soil placed over hot-water pipes or in a close propagating frame, there is no doubt thirty-six hours would not be far short of the mark.

PERPETUAL CARNATIONS FOR NEXT WINTER.—J. H., Leicester: I have four dozen perpetual-flowering carnations now blooming freely in six-inch pots, but I want them to flower next winter, from September onwards. Please tell me what I should do with them to secure good blooms at the date suggested.—Unless there is an abundance of room two-year-old plants are not likely to prove so successful for next winter's flowering as young stock struck early in the present year. Carnations do not respond readily to a severe cutting-back process, such as one might practice upon pelargoniums and similar subjects; consequently they will steadily become taller as the season advances. Remove the flowers as soon as they expand, cutting the stems back to where new growths appear. Pot next month and keep the plants in a cold frame or cool house; pinch back some of the earlier growths so as to render bloom production as curious as possible. We strongly urge you to purchase a few young plants for flowering next winter, and treat them as advised in our columns, because these will give you the finest flowers. The larger and older plants will flower freely, but the flowers will be smaller, and, as already suggested, they will occupy considerable space.

HELPFUL BOOKS FOR THE R.H.S. EXAMINATION.—W. E., Cheshire: Will you please tell me what books would be most useful for a gardener to study for the purposes of sitting for the Royal Horticultural Society's examination in horticulture?—We have answered similar questions on several occasions, but we are rather pressed for space this week, and a full answer would be somewhat lengthy. However, write to the Secretary, Royal Horticultural Society, enclosing a large stamped envelope for reply, and ask for full particulars concerning the society's general examination in horticulture, together with a list of the books suggested as useful for those studying for this examination. We suggest that now, or subsequently, you obtain the papers set at the previous examinations conducted by the R.H.S.; these can be obtained for 2s., and they will prove very helpful to you in your studies, especially if you work at them in your spare time, and get some competent horticulturist to check your answers.

GARDENING ENGAGEMENT.

Mr. J. Davies, for six and a-half years gardener to C. P. Palmer, Esq., Brynheulog, Neath, has been appointed gardener to H. Cuthbertson, Esq., Darran Court, Neath.

Chrysanthemums.—The whole of the stock should now be growing in cold frames. Early attention must be paid to potting on the various batches until they are finally placed in their flowering pots. Attend to the "stopping" of the decorative kinds at the proper time, and give them as much space as is practicable, as overcrowding is favourable to the development of "rust." If healthy cuttings are available it is a good plan to strike a batch now for flowering in six-inch pots. Both the large-flowering and decorative kinds are useful for furnishing the outsides of large groups, when grown in this manner. Spray the whole of the plants with an insecticide occasionally to keep them free from aphis.—E. Harriss, Lockinge Gardens.

CATALOGUES RECEIVED.

CHRISTOPHER BOURNE, SIMPSON, FLETCHLEY.—A dainty and beautifully-illustrated catalogue of daffodils with descriptions of all the finer sorts, and very useful lists of varieties classified according to prices.

V. LEMOINE AND SONS, RUE DU MONTEL, NANCY.—Two very interesting catalogues have reached us from Nancy, one dealing largely with florists' flowers and including novelties in pelargoniums, and the other devoted chiefly to shrubby plants and novelties and rarities, notably among deutzias, hydrangeas, and philadelphuses.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

TUESDAY, May 27.—Messrs. J. Waterer and Son's Rhodendron Exhibition at Horticultural Hall, 4 days.

Bath and West of England Show at Truro, 5 days.

The following dates of exhibitions have been recently announced:—

Epsom Horticultural Society, Rose Show, June 26, at Woodcote Grove; Summer Show, August 4, at Epsom College.

Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.

Ealing Horticultural Society, July 9.

Weybridge Horticultural Society, July 10, at Barbam Lodge, Oatlands Drive.

Edgware Horticultural Society, July 12.

Dulwich Summer Show, July 17, at St. Barnabas Parish Hall; Chrysanthemum Show, November 12 and 13, at the Baths, Goose Green.

Ulverston Rose and Sweet Pea Show, July 18.

Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.

Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.

Tunbridge Wells Flower Show, July 23 and 24.

St. Quintin Horticultural Society, July 24, in the Gun Club grounds Wood Lane, W.

City of London Rose Show, July 26, at Cannon Street Hotel.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Humus.

The presence of humus, or the remains of matter derived from previous generations of vegetation, in the soil is of such recognised imporance to the gardener and agriculturist, that a little consideration of its production and general distribution, and presence, cannot be out of place. Primarily it represents the product of one of those natural successive processes by which life is contantly maintained on the earth's surface. Age after age we see vegetation pass through its phases of reproductive growth and decay. Every spring we see a renewal of active growth and the production of an infinite quantity of fresh vegetative material clothing the world with verdure, and not only providing for its own vital needs, but also for those of the animal world which is entirely dependent upon it. Every autumn we see a return of much of this material to the soil whence it sprang, and we know that in the process of decay an equal quantity becomes available as raw material for future growth. We also know, however, that indedependently of this supply to the root systems, the great bulk of the new growth owes its existence to the carbonic acid gas in the atmosphere, and certain earthy salts in the soil, which, by the potent action of the sunbeam on the green colouring matter of the foliage, the chlorophyll grains are broken up and recombined to form the infinite number of compounds, boons and banes, and the structural material of the plants concerned. Humus, therefore, by itself would appear to provide but a small portion of the nutritive material, but its beneficial effect in the soil is twofold. In the first place, there is no doubt that as it is mainly composed of carbon, its decomposition in the soil results in the restoration of much of its gaseous ingredients to the air, and, in the second place, it renders the soil more open and friable, and thus of easier access to the penetrating roots. Thus it is that alluvial soils brought down by rivers and tributary streams are practically ideal ones for cultivation. Without the general admixture of vegetable debris they would form impermeable clays; with it they are, as we have said, the richest soils we know of. If we follow up such streams to their sources in the hills we shall speedily appreciate how this beneficial admixture is brought about. We shall find in the mountain glens, rock formations which, under the influence of frosts, are constantly being split up, a process which is also facilitated by the expanding and spreading roots of the vegetation which there prevails. The stream itself, from time to time, becomes a torrent, which, invading its boundaries, undermines and brings down into its bed both the disintegrated rock and the vegetation it has borne. These materials are then again attacked by the water, and carried downwards towards the inevitable sea. On the way the rocks are gradually broken up, ground up, and reduced to gravels, sands, and even impalpable mud, while the vegetable debris is rotted and reduced on a similar scale. When such a stream reaches the low-lying valleys and flat lands, which, in times of "spate" or winter storm they invade and overflow, the fine admixture of ground rocks and vegetable remains, freed from the onward impulse of the flood itself, are, to a large extent, deposited to form another layer of the alluvial which has already formed the flat expanse peculiar to such deposits. Below such deposits there are usually found others of gravel, which represent an earlier stage of the stream's history. As regards the annual deposit of the shed foliage, we are probably as yet but on the threshold of discovery as to how it is disposed of so as to reassume its function as a material for future growth. It is but of late years that we have obtained a glimpse of the functions of bacteria in the soil, friendly and hostile. We know by actual experience how an unswept garden pervaded with liberal heaps of dead leafage soon becomes bare of it by means of the worm, which drags the leaves into its burrows, devours them wholly or partially, and thus immediately turns them into rich material available for root absorption. This may be considered probably as the shortest cut to reassimilation. Fungi also play a potent rôle, but, in all probability, it is the microscopic bacterial world which, in the long run, plays the chief one in completing the vegetative cycle.

MR. JOHN A. GRIGOR.

Mr. John A. Grigor, of Sea Park Gardens, Forres, N.B., is widely known as a particularly successful grower and exhibitor of sweet peas and chrysanthemums, but his successes in these directions are but outward and visible signs of his capabilities; and, after all, they are evidences that Mr. Grigor rides a hobby or two while engaged in the wider practice of general gardening. Mr. Grigor's father was thirty years head gardener at Fairfield, Aberdeen, so he commenced his horticultural career under parental guidance, subsequently serving his apprenticeship at Kingskussie Gardens, Aberdeen, and afterwards acting as journeyman at Ching Castle, Dupplin Castle, and Eglinton Castle. The latter Ayrshire seat was Mr. Grigor's farthest south, as from thence he went northward, and held the position of foreman at Drumtochty Castle, Fordoun, for two years, following this up with two and a-half years at Bruckley Castle. The latter is a fine place and from it Mr. Grigor secured the position of head gardener to A. M. Gregory, Esq., at

Maryhill, Elgin, where he laid out a new garden, and took up chrysanthemum culture as a hobby, and with great success. Three and a-half years at Maryhill were followed by six years as head gardener to Sir David Stewart, at Banchory House, Aberdeen, where, as an all-round gardener, Mr. Grigor made a good reputation for himself, and gave every satisfaction to his employer. At present, Mr. J A. Grigor is head gardener to Mrs. Dunbar-Dunbar, at Sea Park, Forres, and it was shortly after settling down here that he made sweet peas a hobby: for a couple of years he cultivated these flowers experimentally, but with such success that in 1911 he practically had matters all his own way when he competed at Aberdeen, Perth, Banff, Edinburgh, and Inverness; four silver cups fell to his share, as well as other awards. In 1912 he led in the Scottish class at the National Sweet Pea Society's exhibition in July and won five first prizes with five exhibits at Perth, one of them being the Scottish Cup offered by the N.S.P.S. for competition among members resident in Scotland. Besides cups for sweet peas and chrysanthemums Mr. Grigor also holds trophies of his skill as a cultivator of fruits and vegetables.

The King's Medal for Roses.—The King has presented a gold medal for competition at the annual exhibition of the Isle of Wight Rose Society, of which Lord Tennyson is the president.

Presentation to Mr. George P. Berry.—On the eve of his departure to take up his duties as General Inspector of Horticulture in England, under the Board of Agriculture, a number of Mr. George P. Berry's horticultural friends in Edinburgh met him in the Royal British Hotel on the 23rd inst., in order to wish him Godspeed and to present him with an address giving expression to their appreciation of what he had done to advance horticultural interests during the time he had occupied the post of senior lecturer in horticulture in the Edinburgh and East of Scotland College of Agriculture, to be followed by a more tangible token of the esteem in which he is held by them at a later date. The chair was occupied by Mr. David King, the president of the Scottish Horticultural Association, who presented the address, and amongst others present were Mr. Alex. M'Callum, M.A., LL.B., director and secretary of the Edinburgh and East of Scotland College; Mr. C. Comfort (Mr. Berry's oldest friend), Mr. Massie, Mr. Whytock, Mr. Fife, Mr. Scarlett, Mr. Todd, Mr. Phillips, Mr. Richardson, and a number of other gentlemen with whom Mr. Berry had been intimately associated during his stay in Edinburgh.

Fine Warm Weather.—The Chelsea Show was favoured with good weather, and consequently with a record attendance, but it was not until Saturday, May 24, that really warm, summer-like weather began, though a change was imminent on the Friday evening. A brilliant Saturday was followed by a still more brilliant Sunday, when glorious summer weather was experienced over a greater part of the country, and cloudless blue skies were the order. In the Metropolis a shade temperature of 80 degrees was common, and in some districts 82 degrees were registered, while in full sunshine the register was up to 120 degrees. Monday, May 26, was equally fine and equally hot, but a slight breeze made the heat more bearable. Tuesday provided another fine, hot day with light breezes. On Tuesday evening, however, a thunderstorm broke over the home counties, and was very severe in some parts of the Thames Valley and in Essex. In the Reading district and in South Oxfordshire fruit and other trees were badly damaged by hail, while at Castle Hedingham a large number of glass-houses were wrecked by hailstones, many of which weighed twelve to the pound. In few places, however, did the storm do harm; indeed, the rain was welcomed by gardeners and farmers after the four hot days. Wednesday, as we go to press, the day is beautifully fine, but there are clouds and a breeze to temper the heat of the sun. The storm of Tuesday night has cleared the air, and freshened up trees, shrubs, and all garden and farm crops.

Fruit Crops in Kent.—The season is now so far advanced that it is possible to estimate with some degree of accuracy the fruit supplies for the coming season. In Kent the prospects are decidedly satisfactory, notwithstanding the damage that was done by spring frosts to the blossom produced early in the flowering season. The crops of apples and pears have the promise of proving highly satisfactory. Early cherries and plums suffered much from frosts, but later varieties were but little injured, and good crops may be anticipated. The gooseberry crop is somewhat uneven, but currants are likely to give an abundant yield, the black varieties, in many districts, being more promising than for some years past. Strawberries promise a heavy crop, the plants being in a robust state of health and producing strong flower trusses.

Wild Flowers of Mahableshwar.—At the meeting of the Royal Horticultural Society at Vincent Square, Westminter, on Tuesday, June 3, at three o'clock, Professor O. W. Müller, M.A., I.E.S., of Elphinstone College, Bombay, will give a short lecture on the "Wild Flowers of Mahableshwar," India, illustrated by water colour drawings by Mrs. Müller.

Window Gardening at Sheffield.—The Sheffield Corporation has voted the sum of £100 for the purpose of promoting window gardening and flower culture generally in the city. The Bowling Greens Sub-Committee will organise the competition, and £5 will be offered as the first prize in each ward.

American Gooseberry Mildew.—According to a report presented to the quarterly meeting of the Kent County Council this destructive disease continues to extend in the gooseberry plantations in Kent. The total area in the county known to be infected is 3,995 acres, and of the area over which the American Gooseberry Mildew has spread, 1,502 acres are in the Maidstone district, 1,350 acres in the Swanley district, and 443 acres in the Sandwich district. The area of the gooseberry plantations that are quite healthy in Kent is 1,461 acres.

Royal Botanic Gardens, Kew.—An addition has been made to the Royal Gardens, Kew, by the purchase of Gumley Cottage, a Georgian house, on the east side of Kew Green, which was built early in the reign of George III. for the accommodation of the Court during his Majesty's long stay at Kew. The house is to be used chiefly for microscopic work.

Newcastle Horticultural Society.—For several years past this society, which is one of the oldest in the provinces, has been greatly hindered in its work by having a balance on the wrong side, owing chiefly to unfavourable weather on the occasion of its summer shows. The deficit at the close of last year was £400, and it was decided by the executive to make a strenuous endeavour to clear the deficiency. The results have fully justified the effort, for already the deficiency fund amounts to £276, and we hope the executive will be able to obtain a sufficient sum to strike a balance before the date of the exhibition.

Street Hawkers of Fruit and Flowers.—At the annual conference, in Glasgow, of the National Federated Associations of Fruiterers and Florists, a resolution was passed urging all Corporations to seek power to register street hawkers. The President (Mr. Boyes, of Leicester) said it was necessary they should make the Home Secretary understand that there was on foot a movement demanding fresh legislation relating to this matter. In supporting the proposal, Mr. McGinnes said that in Liverpool they had, as the result of street trading, miles of empty shops, and that city was losing £30,000 in rates owing to 2,000 shops being shut.

Visits to Altrincham Gardens.—For some years past the Altrincham Gardeners' Association have included in their annual programme visits to notable gardens in the district, and these have been found at once interesting and instructive. This year the first visits were made to the gardens of Dunham Knoll, the residence of Mr. T. Haslam, and of Glenfield, the residence of Lady Crossley, and occupied a long afternoon. At Dunham Knoll the display of polyanthuses, tulips, and wallflowers in the flower garden, and the finely-grown calceolarias and schizanthus in the conservatory, proved highly interesting to the visitors. Polyanthuses were also in a high state of development in the flower garden of Glenfield, and in the conservatory the perpetual carnations were a great source of attraction.

Chelsea Pensioners' Gardens.—It may be of interest to those of our readers who found time to see the gardens of the Pensioners of the Royal Hospital when visiting the Royal Horticultural Society's exhibition at Chelsea that the small gardens were formed by Lord John Russell in 1841 when he was Paymaster-General. He held that office four years, during which time, as he acknowledged, "the work was all done by the cashiers and the only official act of any consequence performed was the giving allotments of garden ground to 70 old soldiers."

Edinburgh Royal Botanic Gardens Guild.—The first meeting of this Guild will be held in the Lecture Hall of the Royal Botanic Gardens, Edinburgh, at 8 p.m., on Wednesday, June 4, for the purpose of electing a president, vice-presidents, committee, secretary, and treasurer. The number of replies from old members of the staff is considered encouraging, and it is hoped that all who can possibly attend will endeavour to be at the meeting.

Wild Flower Show at Glasgow.—During the past six years it has been the custom at this season to supplement the beautiful displays of cultivated flowers in the People's Palace, Glasgow, with contributions of native plants. Much interest is taken in wild flowers, which have labels attached bearing both the common and scientific names, and large numbers of visitors, who but a few years ago were unacquainted with native plants, have become familiar with a considerable number of the wildings growing within a radius of several miles of Glasgow. A few days since we found on the tables flowers of about sixty species, among them being cowslips, broad-leaved garlic, lesser celandine, bluebells, wood anemones, primroses,

golden saxifrage, marsh andromeda, the wild hellebore, wood violets, and the greater stitchwort.

Eradication of Plant Diseases.—At the Rome meeting of the General Assembly of the International Institute of Agriculture, measures for preventing the spread of plant diseases received full consideration. As the outcome of the discussion a committee was appointed to draw up a series of resolutions that would represent the views to which expression had been given. As the result of the work of this committee the following resolutions were submitted to the General Assembly by whom they were unanimously adopted: (1) The General Assembly recommends that the Governments of the countries adhering to the International Institute of Agriculture should, if they have not already done so, create a Government service of phytopathology. (2) Recognising the utility of an international agreement upon the means of preventing the diseases of plants, it is of opinion that the assembling of an international commission of specialists is indispensable: and it expresses a wish that the Government would be willing to follow up the initiative it has already taken in this question, by inviting a meeting of the international commission as soon as possible, during the month of May, 1914, at the latest. (3) It is of opinion that at each General Assembly of the Institute the specialists of the various Governments should meet in a separate commission to discuss the results of their researches ad studies in the diseases of plants. (4) It begs that the countries adhering to the International Institute will at once begin to study the various questions which the International Commission of Phytopathology will have before it, basing their study upon the materials which the International Institute of Agriculture will be able to furnish.

Model Town Garden Competition.—We are informed by the organising secretary of the Ideal Home Exhibition, which will be held at Olympia from the 9th to the 25th of October next, that amongst the competitors for the Gold Cup offered by the "Daily Mail" for the best and most practical model of a garden, suitable for a town and city house, are Messrs. James Carter and Co., of Raynes Park; Messrs. J. Cheal and Sons, of Crawley; and Messrs. W. H. Cook, Lim., of Orpington.

Sale of the Byrkley Lodge Orchids.—The collection of orchids belonging to Sir William Bass is to be sold under the hammer of Messrs. Knight, Frank, and Rutley at Byrkley Lodge, near Burton-on-Trent, early in July next.

The Fairchild Sermon is, in accordance with the custom that has obtained for 184 years, preached at St. Leonard's Church, Shoreditch, on Whit Tuesday, and to horticulturists is of considerable historical interest. Thomas Fairchild, whom the sermon commemorates, was a son of John Fairchild, of Alwine, Wilts, and was born in 1667. When fifteen years of age he was apprenticed to a clothworker, but having no liking for that avocation, he devoted his attention to gardening. He became a nurseryman and market gardener at Hoxton in the early part of the eighteenth century, and attained the position of one of the foremost nurserymen and market gardeners of his time. He was greatly interested in the scientific aspects of horticulture as well as being well versed in the practice of the gardening art, and first became known among scientists by a paper contributed to the Royal Society's "Transactions" (Vol. XXXIII., p. 127) on the "Different and Sometimes Contrary Motion of the Sap in Plants." His garden and vineyard at Hoxton were of much interest, and with reference thereto, Bradley writes in his "Philosophical Account of the Works of Nature" of "That curious garden of Mr. Thomas Fairchild at Hoxton, where I find the greatest collection of fruits that I have yet seen, and so regularly disposed, both for order in ripening and good pruning of the several kinds, that I do not know any person in Europe to excel him in that particular; and in other things he is no less happy in his choice of such curiosity, as a good judgment and universal correspondence can procure." Fairchild corresponded frequently with Linnæus, and in addition to his experiments relating to the flow of sap in plants, he devoted considerable time and attention to the investigation of sexes in plants. Dr. Pulteney refers to Fairchild as follows: "My plan does not allow me to deviate so far as to cite authors on the subject of gardening unless eminent for their acquaintance with English botany. Some have distinguished themselves in this way; and I cannot omit to mention with applause the names of Fairchild, Knowles, Gordon, and Miller." Fairchild published "The City Gardener" in 1722 at the price of one shilling, and in his will he left a sum of £25 for a sermon to be preached annually at the church mentioned above on Whit Tuesday "On the wonderful work of God in the Creation." It should be added that Fairchild died in 1729, and was interred in the old burial ground in Hackney Road, now an open space close to Shoreditch Church.

The Japanese Larch.—Fifteen years since ten plots at Cockle Park were planted for the purpose of demonstrating several important points in forestry, and have proved most useful. According to last year's report, which has been recently published, the most remarkable feature of these demonstration plots has been the highly satisfactory growth of the Japanese larch on poor clay soil. They have outstripped the European larch in growth, and are free from aphis attacks and larch canker, which are so injurious to the European species.

RHODODENDRONS AT WESTMINSTER.

Messrs. John Waterer and Sons, of the American Nurseries, Bagshot, Surrey, held an exhibition of rhododendrons at the Horticultural Hall during the past week.

The popular Pink Pearl rhododendron still holds its own as one of the most lovely of hardy-flowering shrubs, and it was massed here in grand style. It has a rival, however, in Alice, which bears finely-formed trusses of lively rose-pink flowers, and carries these boldly on shapely plants that possess an ideal habit for bedding. A fine lot of this variety filled the central position in the main group, opposite the entrances. Its blooms are scarcely so large as those of Pink Pearl. Another lovely new variety is Corona, which is heavily flushed with coral pink over blush pink, and offers a quite new effect in hardy rhododendrons. Bagshot Ruby is yet another new-comer, and its blooms are of a rich glowing red shade that has suggested its title. Gomer Waterer is not so new, but it is a grand modern variety with superb trusses of large blush white flowers, and the plants have a very fine habit.

Such brilliant red and scarlet varieties as Prometheus, Doncaster, Michael Waterer, and Brilliant provided breadths of rich colouring in the display, and the white George Hardy, delicate blush-coloured Mrs. E. Stirling, and white, maroon-blotched Francis B. Hayes served to accentuate the glowing colours of the other varieties.

WINDOW GARDENING.

Window gardening has of recent years come in for some share of the increased attention given to gardening generally, and it has much to recommend it where the plants so grown do not shut off any desirable view of the garden proper. In living rooms on the ground floor it may easily happen that a row of even moderate-sized zonal pelargoniums, if standing on the window-sill, or on a level with it, will conceal a good deal of the garden from the view of those sitting at the table or anywhere away from the window. If the outlook is towards the road, or our neighbour's house on either side, this is all to the good, but not otherwise. In the case of first-floor windows on the contrary, we cannot usually see much of the garden, in any case, unless we are near the window, and therefore no plants of the height ordinarily used for this purpose can do much in the way of shutting out the garden. Nothing is more delightful than a bank of flowers to look at when one wakes on a spring or summer morning; besides which one can have the windows wide open at the bottom, as many hygienically-instructed people do nowadays, without being unduly exposed to the public gaze before one gets up.

When entering on the tenancy of a house one has to take such arrangements as exist, but when fitting them up for ourselves it is a debatable question what course we shall adopt, though one is very much restricted in the choice of boxes or balconies by the construction of the windows and window-sills, and the general design of the house. The time and labour, too, which one is prepared to spend upon this department of the garden is a very important consideration, but when the plants have been put in position, it is to be assumed that some lady member of the household will regard them as her own particular province, as with pot plants indoors and cut flowers. A good wide window-sill lends itself naturally to movable boxes of flower-pot ware, pottery, or wood, and when this plan is adopted it is very convenient to have a duplicate set of boxes, so that the winter occupants may be ready to put in when the summer ones come out, or the latter ready to put in when the spring plants are beginning to look untidy. This is not absolutely necessary, but it avoids intervals between the seasonal displays when the plants would otherwise look coddled—a thing to be avoided above everything in window gardening. Moreover, a box on the first-floor window-sill is exposed to a great deal of wind, and possibly sun also, and plants newly put in are apt to suffer and look uncomfortable for some time after being planted, and in some cases never look so thrifty and vigorous again.

The alternative to this method is to keep the plants in pots, a more laborious method and one entailing a good deal more attention in the way of watering, as pot plants, if well rooted in the pots, will sometimes need watering once a week, even in midwinter, if the prevailing winds lie the other side of the house, so that the rain does not help them. But this method has the advantage of enabling us to replace any plant that is not doing very well with practically no trouble beyond that of keeping a sufficient reserve supply. By this means, if we do not mind taking the trouble, we need only put plants in when at their best, and only selected ones then.

A row of pots on the bare, open window-sill is, of course, out of the question, even at the back of the house, unless there is another row in some kind of trough, basket, or balcony in front, which will conceal the pots in it, and the plants in which hide

the pots on the sill. We usually see the most effective displays in window-gardening arranged on this principle, tier rising above tier, and when the front row consists of hanging plants and the back row of fairly tall ones, a beautiful bank of flowers may be produced. But a very presentable effect may be obtained from just a narrow balcony able to hold one row of pots only, and placed just sufficiently below the window-sill for the plants on the latter to show well above them, and yet have their pots concealed by plants of even medium height.

A mistake that is often made in window-gardening of this latter kind is in putting the plants in pots which are too small, not only for their proper development of growth, but to enable them to stand up in some measure against the violence of the winds they will have to endure. Many think that a large pelargonium will grow in a forty-eight pot, and so it will, but it will need watering twice a day in hot weather, its growth will be restricted, its period of flowering shortened, and the size of its trusses lessened, while every little wind will blow it over, so that it leans on its neighbour, or, if the pot is standing in a saucer, blow it out of the upright, so that the pot has to be set level before it can be effectively watered, a business which, when multiplied by twenty or fifty, takes time, and is decidedly annoying when you have the can in your hand ready for watering.

Still, though we should put our plants in larger pots than we would if they were to grow in a house, where the atmosphere is moist instead of excessively drying, it is not advisable to give them unduly rich soil, or the two things together will cause such vigorous growth that we shall have more leaf than flower, and this increased leafage wil loffer more surface to the wind. This is especially true of zonal pelargoniums.

Alger Petts.

RHODODENDRON CILIATUM.

This is a pretty Himalayan species, hardier than many from that region. It forms a dwarf, compact bush, and produces its bell-shaped blush-coloured flowers in great profusion. In sheltered spots out of doors it is very effective, but this is not its only claim to recognition, as it forms a delightful feature in the greenhouse, and, furthermore, has proved to be of great value to the hybridist, as it has played a part in the production of many beautiful garden forms, particularly among the tender kinds.

The valuable R. præcox resulted from the crossing of R. ciliatum, and the hardy R. dahuricum, which will often bloom out of doors in the depth of winter, while R. præcox is not far behind it. This last-named was raised over fifty years ago by the late Mr. Isaac Davis, of Ormskirk, but its merits were some years in gaining recognition; indeed, when it was submitted to the Floral Committee of the Royal Horticultural Society it only gained a Second Class Certificate. There is nothing to prevent it, even after this lapse of years, being put forward for the higher honour. R. ciliatum has, in conjunction with the primrose-tinted R. Dalhousiæ, given us R. Countess of Haddington, one of the most popular of greenhouse kinds. Association with R. Edgeworthi yielded R. Princess Alice, intermediate in appearance between its parents, but with the delicious fragrance of R. Edgeworthi itself. Since then a great many other ciliatum crosses have been raised. W.

IRIS TINGITANA.

This iris, which is a native of Tangiers, whence it was introduced into this country in 1872, resembles a glorified Spanish iris. The blossoms are very lovely, the standards being violet-blue, and the falls a delicate French grey, which colour is set off by the gleaming yellow of the central blotch. The flowers measure five inches across and with the falls spread out ten inches. The width of the falls is about two inches, and the height of the standards is four inches.

Although this iris has been known in England for over forty years, it is but little grown, and apparently very few are able to flower it satisfactorily. Numbers of letters appear from time to time in the gardening press deploring this species' persistent refusal to bloom. These failures have not been confined to beginners who have but just taken up the cult of gardening, but many of our most noted horticultural experts have had to admit like ill-success. The late Sir Michael Foster stated that he had never flowered it in the open. Mr. Archer-Hind informed me that he had only flowered it once in thirty years; the late Rev. Henry Ewbank, of Ryde, allowed that for fifteen years it had not bloomed with him, and the late Mr. Wolley Dod said that he had grown it for twenty years without having flowered it, and wrote, "I must confess myself quite at a loss to know what its requirements are," while Mr. Irwin Lynch, in his "Book of the Iris," states that it is not worthy of cultivation, presumably by reason of its shy blooming qualities.

In the face of all these records of failure in the growing of this iris, it is very satisfactory to be able to record an unqualified success. Some years ago, when Mr. Elwes paid me a visit, we got on the subject of tender plants, and he said he thought it useless to employ the same soil in this country as that in which they thrived in their native land. Plants which in their homes grow in sand would not flourish in that material in England, but required richer soil to make up for the change of climate. I carefully considered this view, and, having heard that Iris tingitana grew in sand, determined to take Mr. Elwes's advice. I had grown this iris for some years with complete want of success, while it was left in the ground during the winter, but with an infrequent flower when it was lifted after the foliage had died down and replanted in the late autumn. I had, however, invariably grown it in sandy soil.

In preparing the new bed a deep layer of manure was placed eight inches below the surface, and with the upper soil was mixed an equal proportion of old mushroom bed manure, so that it was extremely rich. The bulbs were put in at a depth of three inches, and completely surrounded by silver sand. The next year there were twenty-nine flower-spikes from thirty bulbs, and another year eleven out of twelve bloomed, and for years this iris has flowered superbly. However, this year there are no flowers, probably owing to the bulbs not being properly ripened during the wetness and darkness of the preceding summer. The bulbs are invariably lifted when the foliage has died down, and are kept in a dry drawer until the end of October, when they are replanted. If they are left until the middle of November the tops will have begun to grow, but this does not appear to affect their blossoming.

The blooming season of Iris tingitana is very erratic. Perfect blossoms are sometimes produced as early as January, and from that date they flower until the end of April. Last year they were at their best in the third week of April. Some time ago I received a letter from a correspondent asking if I would inform him how I succeeded in flowering this iris. I sent full cultural particulars, and in the following year was glad to receive a letter from him saying that he had followed my instructions implicitly, with the result that his irises flowered very well. Anything that will tend to induce this lovely iris lay asides its shy-flowering habit and become an abundant bloomer is well worthy of note. Wyndham Fitzherbert.

TRIAL OF POWDER SPRAYERS AT ASHTON

Under the auspices of the Royal Agricultural Society, a competitive trial of hand-worked powder sprayers took place at the National Fruit and Cider Institute, Long Ashton, near Bristol, on Friday, May 23. For the probable reason that makers have not paid as much attention to dry as to liquid machines, there were not many entries. Only six competed, and the judging was in the hands of Mr. C. S. Martin, late manager of the Toddington Orchard Company, and Mr. Young, of Wisbech.

For the purpose of the trial powdered lime, flowers of sulphur, and Bordeaux powder were used, and the first appliances to be used were those furnished with wheels. Messrs. Weeks and Sons, Maidstone, entered a somewhat complicated dry powder sprayer mounted on two wheels, and so arranged that it works automatically as it is drawn along, and is turned by hand when it is stationary. The same firm also sent another machine of similar type, but travelling on one wheel.

Messrs. F. Randell, Lim., North Walsham, sent a machine of a quite different design. This sprayer was mounted on small wheels, and it appeared very rigid when at work. The power is obtained by means of a pump, the upward and downward strokes of which play their parts in the working of the machine. The hopper containing the powder is fitted with an agitator to keep it moving.

Messrs. D. T. Gralton and Sons, Newleake, Boston, Lincolnshire, sent a machine which distributes the powder by means of a fan arrangement, and made under the same patent as their dry potato sprayer. There were good points about this sprayer, but it was not very portable, and it suffered for the want of an agitator.

Having carefully tested the wheeled apparatuses, the judges proceeded to test the merits of the knapsacks, and eventually gave the first prize to one of German make called the "Grun," and exhibited by Messrs. Moellenkamp and Co., 85, Farringdon Street, London, E.C. This machine is furnished with a round tank, and is easily carried on the back. The adjustments for regulating the amount of powder distributed are simple and ingenious, and powder that is lumpy is ground fine before it is sent out.

Messrs. Pilter and Co., 22, Bush Lane, Cannon Street, London, E.C., took the second prize with a machine called the "Pilter," which is largely used in Indian tea gardens and rubber plantations. This sprayer, which is carried on the back, is easily worked. Another competing knapsack was sent by Messrs. H. Hartjen and Co., Noble Street, London, E.C. It has a mechanical grinder, a bellows lever, and an arrangement for graduating the amount of powder distributed. There did not seem to be very much to choose between the three knapsack sprayers, and any of them would be useful for dry potato spraying in gardens, and sulphuring strawberries, roses, and other plants.

Parsnips.—From seeds sown early in March the plants will be forward enough for thinning. After completing this operation, hoe the ground between the rows, and apply a light dressing of soot when the plants are damp.—W. Messenger, Woolverstone Park Gardens.

NEW PLANTS AND FLOWERS.

ROSES.

Mrs. J. Campbell Hall. This fine, large, light cream-coloured tea-scented rose we have previously described, and now illutsrate it. A.M., R.H.S., May 20. Messrs. Alex. Dickson and Sons, Newtownards.

Irish Fireflame.—An exquisitely beautiful single rose, and forming an addition to the series of lovely single varieties that has emanated from Newtownards. The bronzy-green leaves form a fine setting to the lovely golden flame-coloured blooms. The buds are redder than the open flowers. A.M., R.H.S., May 20. Messrs. Alex. Dickson and Sons, Newtownards.

White Tausendschon.—Those who admire and prize the beautiful climbing rose Tausendschon will be glad to welcome its white counterpart. Apparently as free in growth and flowering as the type, this bears large, rounded blooms of purest whiteness. A.M., R.H.S., May 20. Messrs. Wm. Paul and Son, Waltham Cross.

ODONTOGLOSSUM QUEEN OF GATTON.

A strikingly beautiful odontoglossum, and a finely-grown one, its spike carrying fifteen fully expanded flowers. The ground colour is nankeen-yellow, this showing at the tips of the sepals and petals, and as veinings through the blotches and spots of rich red-brown. The lip is white, spotted with rose-purple and red, and with a little yellow tinting on the apex. The largest flowers were three inches across. F.C.C., R.H.S., May 20. Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

ODONTOGLOSSUM GEORGIUS REX.

A regal orchid, its yard-long branching spike bearing thirty very fine blooms. Each flower was about four and a-half inches across, with white, rose-tinted ground colour; on the petals the greater part of the surface is occupied by rich red-brown colouring, but on the sepals this rich colour is broken up into blotches and spots. The lip is broad and rounded, pale yellow, with golden disk and fine central deep red-brown

ROSE MRS. J. CAMPBELL HALL.

A new, large-flowered tea-scented variety, with creamy-white flowers. A.M., R.H.S., May 20. Messrs. Alex. Dickson and Sons, Newtownards.

markings. A.M., R.H.S., May 20. Messrs. Charlesworth and Co., Hayward's Heath.

ODONTOGLOSSUM EXIMIUM ARMSTRONGÆ.

This striking variety has a distinct and fairly wide margin of pure white around its red-purple colouring, and in most of the blooms these colours were very well defined. There were nine fine flowers on the spike exhibited. A.M., R.H.S., May 20. Messrs. Armstrong and Brown, Tunbridge Wells.

ODONTOGLOSSUM ILLUSTRISSIMUM WESTONBIRT VAR.

This bold and beautiful variety had eight very handsome flowers of good shape and large size. The sepals and petals are chocolate-red, rose tipped with darker rose shading round the apices, and whitish edges to the segments. The lip is deep chocolate-red with a broad white apex. A.M., R.H.S., May 20. Lieut.-Colonel Sir George Holford (grower, Mr. H. Alexander), Westonbirt, Tetbury, Gloucester.

ONCIDIODA COOKSONIA ILLUSTRIS.

This is a lovely form of one of the most modern hybrids, produced by crossing an oncidium with an odontioda. The spike was slightly branched at the apex, and carried ten brilliant orange-scarlet flowers, with an under-lie of yellow, the latter colour showing through towards the tips of the petals, and on the three-lobed lip. The latter has a prominent yellow crest. One of the most outstanding orchids in the show. A.M., R.H.S., May 20. Messrs. Sander and Sons, St. Albans.

ODONTIODA CHANTICLEER ORCHIDHURST VAR.

In colouring this must stand as one of the most brilliant of the odontiodas, and one of the finest forms. It carried fifteen open flowers, besides several buds. The colour is deep orange-red with a yellow crest. About two inches across, the blooms were of quite rounded form, and their setting on the spike was good. F.C.C., R.H.S., May 20. Messrs. Armstrong and Brown, Tunbridge Wells.

ODONTIODA CHARLESWORTHI PERFECTION.

A superb variety, carrying a dense spike of rounded flowers of wonderful substance, the segments being thick and fleshy. The colour is not easy to describe, but brilliant red—almost blood-red—about fits it. The lip has more scarlet in it, and the bold crest is rich yellow. A.M., R.H.S., May 20. Messrs. J. and A. McBean, Cooksbridge.

ODONTIODA CHELSEAENSIS VAR. ST. FUSCIEN.

This is the finest form of O. Chelseaensis yet exhibited, and the well-grown plant produced a spike of twenty flowers and buds. Each flower was 2½ inches across, and of a bright pink, rose-tinted shade, with buff-pink tips to sepals and petals. The pale yellow lip is bright pink in the centre, and has a rosy apex. A.M., R.H.S., May 20. Mons. H. Graire (gardener, Mons. de Voss), St. Fuscien, Sains, France.

ONCIDIUM McBEANIANUM.

A fine hybrid between O. macranthum and O. superbiens, and combining the freedom and other good qualities of both parents. The spike is of great length and branched. The flowers are about three inches across, the sepals light greenish-brown, and the petals pale yellow with brown bars and spots. The small lip has a small purplish crest. A.M., R.H.S., May 20. Messrs. J. and A. McBean, Cooksbridge.

ODONTONIA LÆLIA SANDER.

This is one of a very distinct series of hybrids. This form is the result of crossing Miltonia Warscewiczi with Odontoglossum amabile. It shows the influence of M. Warscewiczi very markedly in the broad lip and the shining rich brown markings on it. The sepals and petals are also bright brown, tipped with white, and the lip has also a wide white apex, and a bold golden-yellow crest. A.M., R.H.S., May 20. Messrs. Sander and Sons, St. Albans.

CATTLEYA MENDELI MAY QUEEN.

With broad, white petals and sepals, and a bright purple apex to the fringed, frilled, and daintily yellow-throated lip, this chastely beautiful variety was much admired, and the more so because the plant carried one spike of three and another of four large blooms. A.M., R.H.S., May 20. Messrs. J. and A. McBean, Cooksbridge, Sussex.

CYMBIDIUM GOTTIANUM SUPERBUM.

A further improvement is the series of hybrids derived from Cymbidium insigne. As shown, it carried a pair of large, bold blooms, four inches or more across, white, faintly tinged with pink, and with a rose-pink flush along the back of the dorsal sepal. The lip is white, spotted, and lightly barred with red-brown, and with a light yellow crest and stain of yellow on the front lobe. A.M., R.H.S., May 20. Messrs. J. and A. McBean, Cooksbridge.

LÆLIO-CATTLEYA APHRODITE SPLENDENS.

A very fine form, its broad petals pure white at the base, but gradually shading to pale rosy-mauve at the apex. The narrow petals are similarly coloured, and this shading is delightfully effective. The large, almost circular, lip is intense royal purple with creamy throat, that is veined with purple. A.M., R.H.S., May 20. Messrs. Armstrong and Brown, Tunbridge Wells.

LÆLIO-CATTLEYA BOYLEI GATTON PARK VAR.

L.-c. Boylei was produced by crossing Lælia anceps with Cattleya Trianæ, and it has the growth and extending spike of L.-anceps with broader cattleya-like flowers. In the Gatton Park variety the flowers are almost pure white; in the wide open lip the delicate blush-pink, frilled apex emphasises the beauty of the light yellow throat. F.C.C., R.H.S., May 20. Sir Jeremiah Colman, Bart. (gardener, Mr. J. Collier), Gatton Park, Reigate.

LÆLIO-CATTLEYA BRITANNIA WESTONBIRT VAR.

This glorious lælio-cattleya formed the central feature of the Westonbirt collection of orchids at the Chelsea Show, and it was figured in our issue of May 24. A grand plant it carried seven wonderful flowers with broad soft lilac-mauve petals and paler sepals, and a broad, well-expanded lip of richest purple hue with golden throat and pale mauve margins. F.C.C., R.H.S., May 20. Lieut.-Colonel Sir George Holford, Westonbirt.

LÆLIO-CATTLEYA GANYMEDE HOLFORD'S VARIETY.

This brilliant orchid was represented by a fine plant which bore two spikes, each 2½ft. long, measured from the base of the pseudobulb; one carried eight and the other seven flowers, each with a spread of six or seven inches. The petals are soft yellow, orange tinted; the broader petals rosy-orange, and a lovely shade; the lip deep yellow in the throat, with a ruby-coloured apex and rim. A.M., R.H.S., May 20. Lieut.-Colonel Sir George Holford, Westonbirt.

LÆLIO-CATTLEYA SYLVIA VAR. PRINCESS VICTORIA LOUISE.

A charming hybrid from L.-c. Phœbe and L.-c. Ascania. Only two of its half-dozen flowers were expanded, but these were sufficient to show what a fine appearance a large plant in bloom would have. The broad sepals and petals are of a light chrome yellow shade, and the frilled lip is of similar colour, with deeper yellow interior, and some bright crimson and purple markings across the squarish apex. F.C.C., R.H.S., May 20. Messrs. Charlesworth and Co., Haywards Heath.

MILTONIA CHARLESWORTHI.

A very distinct and beautiful miltonia derived from M. Hyeanum crossed with the fine M. vexillaria var. G. D. Owen. The large flowers are of a very pretty shade of rich old rose, with a butterfly-like blotch of dark maroon at the base of the broad lip; the lower sepals bore also a maroon mark at the base. F.C.C., R.H.S., May 20. Messrs. Charlesworth and Co., Haywards Heath.

MECONOPSIS DELAVAYI.

An interesting little plant, with somewhat spathulate, dark green leaves that are scarcely more than half an inch across at their widest part, and are three to four inches long. From the centre of a tuft of leaves the flower appears at the end of a peduncle from four to six inches long. As shown the flowers seems pendulous at the end of the stem; they are an inch and a-half broad, and rich blue-purple, with a central cluster of blue-purple stamens, tipped with golden anthers. A Chinese species, and probably the newest plant at Chelsea. F.C.C., R.H.S., May 20. Professor I. Bayley Balfour, Regius Keeper of the Royal Botanic Gardens, Edinburgh.

SAXIFRAGA GRANDFIELDI.

A capital saxifrage of garden origin. It has sturdy clustering rosettes of stout, white-edged leaves and spikes of white flowers. The spikes are about a foot or so high, branching loosely and carrying three or four shapely flowers, each about half an inch broad, at the ends of the branches. One large flower terminates each spike, but it is almost hidden by the shorter upper branches. One may hazard that S. pyramidalis was one parent of this useful garden plant. A.M., R.H.S., May 20. Sir Everard Hambro (gardener, Mr. Grandfield), Hayes Place, Kent.

STYRAX WILSONI.

A particularly elegant and graceful shrub from China. It has slender, wiry branches that flower freely upon the side twigs, the pure white pendant blossoms appearing in twos and threes in alternate clusters. On one branchlet about five inches long we counted twenty-six of these dainty blooms. The pale yellow anthers add to the beauty of this very pretty shrub. At Great Warley this shrub has proved hardy during a period of four years, but at Kew a good-sized plant has had its branches cut back by severe weather, but did not succumb. A.M., R.H.S., May 20. Miss Willmott, V.M.H. (gardener, Mr. C. Fielder, V.M.H.), Warley Place, Great Warley.

OLEARIA CHATHAMICA.

This is a rare shrub collected some time ago in the Chatham Islands by Captain Dorrien-Smith. As shown it was a yard or so high, branching along the upper half, and producing white, downy branches with alternate lanceolate green leaves, with crenate-serrulate margins, and white downy undersides. Most of the branches bore a terminal flower-head slightly over two inches broad, with about three dozen palest lavender ray flowers around a cluster of purple florets, the reddish-brown stigmas being slightly exserted. Botanical Certificate, May 20. Rev. A. T. Boscawen, Ludgoan Rectory, Long Rock, Cornwall.

CAMPANULA STEVENSI NANA.

A dense-growing variety scarcely three inches high, and forming a close matt of narrow-leaved growths, studded with inch wide, erect bells of a bright rosy-lilac shade, with the finest veins of a deeper hue. A useful rock garden plant. A.M., R.H.S., May 20. Mr. Reg. Prichard, West Moors, Wimborne.

NEPHROLEPIS EXALTATA WILLMOTTÆ.

One of the loveliest ferns imaginable, and one extremely difficult to describe. The fronds are divided most minutely, and somewhat curled, so that a plant looks like a lot of the most exquisite moss piled up by fairy fingers. All the ladies fell in love with this beautiful plant, and with one accord they referred to it as "cool-looking and mossy." It is a sport from N. Marshalli compacta. F.C.C., R.H.S., May 20. Messrs. H. B. May and Sons, Edmonton.

SARRACENIA BRUCEI.

A very handsome sarracenia, with tall, erect pitchers, green below, but with a crimson rim and deep crimson veinings in the

throat. The wide frilled lid is white and pale green, with heavy reiterating crimson veins. A most interesting hybrid, evidently from S. Drummondi and S. Atkinsoni. A.M., R.H.S., May 20. Mr. A. J. A. Bruce, Chorlton-cum-Hardy, Manchester.

CUPRESSUS FLETCHERI.

A very neat pyramidal conifer that grows only about fifteen inches or eighteen inches high, and is of sturdy, compact habit. It grows densely, and is of elegant appearance, and should prove a very useful shrub for large rock gardens and for grouping in the pleasure grounds near the house. F.C.C., R.H.S., May 20. Messrs. Fletcher Bros., Ottershaw Nurseries, Chertsey.

CALCEOLARIA CLAREFIELD GEM.

This is one of the most beautiful of herbaceous calceolarias that should become very popular for greenhouse and conservatory decoration, rivalling C. Clibrani in grace and brilliance. The foliage is narrower, but otherwise very like that of the popular florists' varieties, but the branching clusters of intense yellow, crimson dotted flowers rise about a yard high. Plants in 48 and 32-sized pots become perfect sheaves of brilliant blossoms and possess an elegance quite wanting in the dense compact sorts. A.M., R.H.S., May 20. Mrs. Litkie (gardener, Mr. Hulbert), Clarefield, Pinkney's Green, Maidenhead.

AURICULA WILLIAM SMITH.

A green-edged show auricula, bearing a large truss of bloom. The wide green edge is divided from the central white paste by a blackish zone. A fine grower, and of high quality. A.M., R.H.S., May 20. Mr. Jas. Douglas, Great Bookham.

ROSCOEA CAUTILOIDES.

A hardy Chinese plant, introduced in 1907. Its erect growths produce two or three sheathing leaves and from the centre extends a spike carrying several flowers at the apex. Though individual blooms are not long lived, there is a little succession to carry on the effect. The blooms have a quite orchid-like appearance, the large bilobed lip being the chief attraction of the pale yellow flowers. A.M., R.H.S., May 20. Messrs. Bees, Lim., Liverpool.

BEGONIA LENA.

A pendulous, tuberous-rooted begonia that makes a fine basket plant, flowering most freely and producing elegant, fair-sized, soft red, semi-double flowers. A.M., R.H.S., May 20. Messrs. Blackmore and Langdon, Twerton-on-Avon, Bath.

ASTER FALCONERI.

A very fine aster, growing about a foot high, as shown. The soft green leaves are stem-clasping, pointed, and hairy; the stems are also hairy. Each growth is surmounted by a flower head four and a-half inches across, and of a pretty mauve-blue shade. A yellow disk adds to the beauty of this Himalayan plant. It is quite hardy, and should prove very useful for the rock garden and for the border. A.M., R.H.S. May 20. Messrs. Barr and Sons, King Street, Covent Garden, London.

PENTSTEMON DAVIDSONI.

A lovely shrubby species growing only two or three inches high, and of prostrate habit. The neat, small, rounded leaves are closely set and greyish-green. Compared with the size of the plant and leaves, the flowers are large, being two-lipped, an inch and a-half long, tubular, and of a pretty old rose shade of colour. P. Davidsoni comes from the Rockies, and was first found by Mr. Elliott in a private garden in Surrey, and apparently has been but recently introduced to cultivation from its native habitat. A.M., R.H.S., May 20. Mr. C. Elliott, Stevenage.

LONICERA TRAGOPHYLLA.

A Chinese species of robust growth, and one that produces long, tubular, light yellow flowers that are sweetly fragrant. The flowers are about four inches long, and some of the clusters carry eleven blooms. A.M., R.H.S., May 20. Messrs. Jas. Veitch and Sons, Chelsea.

LADY GARDENERS.

Having for the past ten years conducted the examinations of the pupils of the Practical School of Gardening in connection with the Royal Botanic Society of London, I may be allowed to offer a few remarks on the question of the general efficiency of lady gardeners. At the Lyceum Club, on the occasion of the first dinner of the Agricultural and Horticultural Section, the well-known writer, Mrs. Flora Annie Steel, in replying to the toast of "Open-air Women," gave a charming account of her gardening experiences, and dwelt at some length on the subject of women gardeners.

But the adaptability of women as gardeners did not appear to me to be fully considered by any of the speakers, and as this point has been frequently discussed in the gardening press of late, I would like to add my quota to the subject. Roughly speaking, about one-half of the pupils who have presented themselves for examination during the past ten years were women, but of late the number of the latter has been decidedly on the increase.

The examination, which is conducted on both practical and theoretical lines, consists of a general knowledge of gardening operations—making and inserting cuttings, grafting and budding, seed sowing, pruning, trenching and ground levelling, dealing with insect pests, etc., while the list of questions to be answered in a given time relates to the laying out and planting of a garden, plants for various soils and sites, the cultivation of vegetables, fruit and flowers, and the best means of dealing with various soils—in fact, everything that pertains to the vegetable or flower garden, from the purchase of the ground to its final cropping.

Though the general all-round efficiency of the pupils, both men and women, after a three-years' course of instruction is parcularly good, yet, I must admit that the theoretical part is more ably carried out by the women than the men. Not only is the scope of the question more fully considered, but, generally speaking, a greater amount of detail and careful preparation is to be found in the papers of the women. With reference to the practical operations they can, as a rule, be more efficiently carried out by the men, but here again the work of the women is far and away beyond reproach. Whether lady gardeners will succeed as heads of large establishments where men are principally employed, I am not prepared to say, but there is no reason why, as advisers, both public and private, or in the management of the smaller gardens and grounds, they should not do equally well with men; indeed, at the present time, several important posts in connection with gardening and the laying out of new grounds are being ably filled by women.

The occupation, too, is a healthy one, and for this reason alone many women have been induced to join the ranks of the gardening profession.

A. D. WEBSTER.

NEPHROLEPIS EXALTATA WILLMOTTÆ.

A beautiful, moss-like fern, with finely-divided foliage. The most dainty of all the exaltata varieties. F.C.C., R.H.S., May 20. Messrs. H. B. May and Sons, Edmonton

See page 394.

Mulching.—Late planted shrubs, either deciduous or evergreen, should be given a good mulching of some moisture-retaining material if such work was not carried out as planting proceeded; rotten manure is best for this purpose except in the case of the delicate kinds of American shrubs, when a dressing of peat or leaf-mould will be more suitable. Grass mowings can be used when nothing better is at hand, but it requires to be moved occasionally, otherwise the surface settles down and becomes impervious to water. Some inhabitants of the flower garden will be greatly assisted if mulched with manure, especially pæonies and delphiniums. Mulching becomes a most important operation when circumstances do not permit watering to be carried out in an efficient manner.—T. B. FIELD, Wych Cross Place Gardens.

NOTES FROM KEW.

Though many of the bulbs and forced shrubs that have for some time formed a bright and attractive feature in the large greenhouse at Kew are now practically over there is no lack of flowers in that ever-popular structure.

The practice generally prevails of arranging the plants in groups or masses of one particular kind, and in this way the beauty of the different subjects is seen to the best advantage.

Calceolarias.

One of the most striking things is a large semi-circular bank of Calceolaria Clibrani, the plants being about four feet high, and as much through. This calceolaria is certainly most valuable for greenhouse or conservatory decoration, as not only can large plants be obtained, but they are light and elegant in contour compared with many of the garden forms. A group of smaller examples in another part of the structure serves to show its beauty when grown in this way.

Calceolarias of the herbaceous section, with flowers large in size and brilliant in colouring, are also numerous, while a pretty shrubby species, C. violacea, is also flowering freely. This, which forms a fair-sized bush with slender shoots, has rather small helmet-shaped flowers, in colour white or nearly so, and plentifully spotted with purple.

Many subjects that one would naturally expect to see at this season are freely represented, namely, carnations, cinerarias, hippeastrums, Primula sinensis, Primula obconica, pelargoniums of different sections, spiræas, eupatoriums, stocks, and nemesias.

Uncommon Plants.

These include the comparatively new Rehmannia Kewensis, Erlangea tomentosa, and Statice Suworowi; Arctotis aspera and Arctotis aureola, shrubby composites with whitish and golden-yellow flowers respectively; the rose-coloured Oxalis floribunda, valuable as a basket plant; the strange and gorgeous Strelitzia Reginæ; Impatiens Oliveri, a giant mauve-coloured balsam; several begonias, Coleus shirensis, with long spikes of purple flowers; Eupatorium ianthinum, with large heads of lavender-coloured blossoms; Kalanchoe Felthamensis, a hybrid kind of taller growth, and with deeper-coloured flowers than the well-known Kalanchoe flammea; and a large batch of Primula malacoides, which shows this charming species at its best.

ODONTOGLOSSUM GEORGIUS REX.

A large-flowered hybrid of the O. Lambeauianum section. Ground colour white, tinted rose, and heavily blotched with deep red-brown, almost crimson. A.M., R.H.S., May 20. Messrs. Charlesworth and Co., Haywards Heath. See page 393.

Hard-wooded Plants.

A great many of these contribute their share to the floral display, notable among them being several heaths, namely, Erica persoluta alba, white; E. propendens, lilac; E. Wilmoreana, rosy-red; E. candidissima, white; and E. ventricosa, a kind of purplish-red. This last-named species is, from its dense growth and profusion of flowers, well suited for growing as small plants. The sense of smell reveals the presence of a few belated flowers of Boronia megastigma, while other members of the same genus still in flower are B. elatior, B. heterophylla, and B. fastigiata. Indian azaleas are now for the great part over, but there is a fine batch of that pretty little rich-coloured variety Hexe, grown, as it so generally is, in quite small pots.

Another pretty hard-wooded plant is the Australian Aotus gracillima, whose long, slender arching shoots are densely packed for some distance with small pea-shaped flowers, in colour red and yellow.

Climbing and Pillar Plants.

The roof of the greenhouse is always more or less gay with climbing plants, and just now many of them are in a very attractive condition. Abutilons are very showy, even though Abutilon insigne, which has been in bloom for a long time, is nearly over. Others now in full flower are Boule de Neige, white; and Golden Fleece, yellow, as well as the slender-growing A. megapotamicum variegatum. There are two quite distinct kinds of this grown at Kew, one being apparently the type, and the other a garden form.

Loose growing fuchsias are also very pretty, while two pillar plants stand out in a conspicuous manner. They are Streptosolen Jamesoni, which botanists tell us is really a Browallia. In its warm, reddish-orange colour it is, however, very distinct from any of the generally grown kinds of Browallia. The other pillar plant is Lantana salviæfolia, which is often bedded out in parks and gardens under the name of Lantana delicatissima. It is, however, rarely seen as a pillar or roof plant, though it has been long grown in this way at Kew, and has for years gained many admirers.

Despite the number of new roses, that good old variety, Gloire de Dijon, is by no means out of the running, as a large plant secured to the roof and laden with blossom will testify.

An uncommon and beautiful climber that fully merits a note to itself is Lathyrus pubescens, which is trained up one end of the greenhouse. Good examples have often been shown at Kew, but it is decidedly uncommon in gardens. The flowers, freely borne in clusters, are of a lavender shade, a very pleasing tint.

K.

Prunus sinensis flore plena.—This is usually seen grown as a subject for forcing, but given a specimen on its own roots and planted in a sheltered position, it forms a delightful little outdoor shrub. The comparatively large, double flowers clothe the rather upright shoots for some distance. It is often increased by grafting, but plants on their own roots can be readily increased by layers.—W.

Salsafy and Scorzonera, if properly cultivated, are very acceptable additions to winter vegetables, and for the main crops seeds may be sown at the present time with the full assurance of success. Ground manured for a previous crop and deeply stirred will prove suitable. Apply a surface dressing of burnt refuse and soot, which should be well raked in; draw the drills fifteen inches apart, and an inch deep, sow thinly, and eventually thin the plants to six inches apart.—W. MESSENGER.

CAMELLIA RETICULATA.

The Queen of Camellias should commend itself to everyone having large conservatories or winter gardens to furnish, as in leaf and flower it is one of the most lovely members of a once popular genus. C. reticulata is almost hardy, as it succeeds in the open in favoured parts of the country, and only requires the protection of an unheated greenhouse, in colder parts, to grow it to perfection. Good specimens may be grown either in pots, or planted out against a wall, although the natural habit and greatest beauty are displayed when one is planted out and forms a bush free from all restraint. Like other members of the genus, it does best in a good holding compost of loam and peat, with some sharp sand added, the whole being well mixed previous to using. When potting or planting, the soil should be firmly rammed, as camellias, being extremely hard-wooded, are rarely satisfactory in loose soil. Watering also calls for careful attention at all seasons, and when actually required should be given in quantity, so as to saturate the body of soil.

The foliage of Camellia reticulata is distinct, being long and pointed, and having the margins finely toothed in a regular manner. It is in the flowers, however, that its great beauty lies. These are of immense size, semi-double, of anemone form, and coloured a glowing shade of rich pink, relieved by the soft contrast of the golden anthers that protrude amidst the petals. When grown under cool conditions, it flowers towards the end of March or early in April, and remains effective for three or four weeks. A feature of interest is that it blooms in a quite small state, as plants only 15in. in height will not infrequently carry half-a-dozen flowers.

THOMAS SMITH.

Coombe Court Gardens.

THE BEST AUBRIETIAS.

The ever-increasing popularity of aubrietias, as spring bedding and rock garden subjects, is but a fitting tribute to the value of this group of hardy plants for decorative purposes. Whether as a carpeting subject for beds, as an edging plant, or for creating beauty upon an old wall, or in drifts down the rock garden, few groups of early-flowering plants can equal, and certainly none surpass, a really good selection of aubrietias.

My list of the best aubrietias may be freely criticised, but I wish to say that my choice is based simply upon my own observations of recent years.

Many observers have put it on record that Lloyd Edwards is the best deep-hued aubrietia. This is a good useful variety, very neat in growth, but it is hardly the equal of the renowned Dr. Mules, as grown here. Dr. Mules is indispensable, and with it I would bracket Excelsa, Duke of Richmond, Invicta, and Hokkaido, as especially fine varieties of very rich colouring.

Rather lighter in hue, having more of a reddish tone in the purple, are Lady Constance, the earliest of all aubrietias, and the fine Eastern Beauty, a direct descendant of Dr. Mules. In the reds Bonfire leads at present; it is a fine glowing colour. Mars is also very good, while Vivid, Boatswain, and Prince John are among other notable forms. These are superior to Fire King, and of better colour than the larger-flowered Alfred Wilcox, both of which have rendered good service.

Of the pinks, Bridesmaid, a very pale variety; Moerheimi, a good round-flowered neat grower. Charming, a sterling, bright pink; and Princess, rather paler, are all extremely good, while Lilac Queen, a rosy-lilac, is near enough to be included in this section.

It is a difficult point to decide within the group of what I will term blue sorts, i.e., those varieties with flowers having blue as the dominant colour, and not sufficiently deep to merge either into purple or violet. Perkinsi may be noted here; also Prichard's A1; both are good. Heroine is a strong-growing, exceptionally early novelty of great merit.

Lavender is a first-rate form, the best of the lavender shades; the seedling Fairy comes very near in colour, but is quite distinct.

The best six, in my opinion, taking the whole group through are Lavender, Bonfire, Invicta, Excelsa, Dr. Mules, and Eastern Beauty, though one could possibly select another half-dozen very near to these.

Clacton-on-Sea. P. S. HAYWARD.

A SWEET-SCENTED BORDER.

Borders near paths, dwelling-room windows, or even in odd corners, may be made most charming by sowing thinly, seeds of the following kinds of annuals now: Mignonette should form the ground-work, and Shirley poppies, still more thinly grown, should be seen above the mignonette. An edging of night-scented stock, Mathiola bicornis, will complete the border. For many years I formed some borders in this way, and they were always greatly appreciated. The mignonette must be thinly sown; then the plants branch out and continue to flower throughout the season. The poppies are still more thinly grown, so as to prevent any overcrowding. If there is crowding the plants do not last long enough. GEO. GARNER.

CUPRESSUS LAWSONIANA FLETCHERI.

A dwarf, greyish-green variety, of compact habit and of retinospora-like appearance. Grows about 18 inches high. F.C.C., R.H.S., May 20. Messrs. Fletcher Brothers, Ottershaw Nurseries, Chertsey. See page 395.

SWEET PEAS.

Culture under Glass.

The cultivation of sweet peas under glass has extended to an enormous extent during the past few seasons, and, judging from the results obtained by experienced growers, glass culture is likely to increase for some time to come, especially for market supplies, at least until the inevitable happens—the price falls so low that it does not pay well enough to warrant the outlay. Unfortunately, the amount of light and sun during the early months of the year is not sufficient to allow sweet peas to bloom much before the first week in May, although last season we had them in good condition some fourteen days earlier, but it must be remembered that we had an exceptional amount of bright weather during April. This season has been very different, and the growth has kept soft and been somewhat more inclined to bud dropping than ever. I have noticed this before, that growers might note that, although they may sow very early—even in August, it does not follow that they will obtain correspondingly early supplies of flowers. Strong early plants kept very hard are a decided advantage, and mid-September sowings are most likely to give good results. Plants raised at that period were quite tall and strong enough by the first or second week of April to carry good flowers if the weather conditions had been such as to allow them to retain their buds.

It is not always want of light that induces the plants to shed their buds; too generous treatment in the early stages, and a temperature in excess of requirements are both potent factors, and, although at no time must the plants be hurried, it is especially desirable to keep them steady just as the first flower buds are pushing.

This stage has, however, been passed for the present season, and the plants are now flowering quite freely, and to keep them growing freely and giving good long-stemmed flowers, the plants may be treated quite liberally. When in pots it is astonishing the amount of water and manure they will take, and during really hot weather a good damping down with the hose will help them materially.

In good lofty houses the plants, if hard, will stand a good deal of sun, but it is best to give a little shade now to keep down the temperature somewhat. Referring again to bud dropping, when looking through a large house of sweet peas quite early in April, I noted several odd plants that had not dropped a bud; they were evidently rogues (white) that had cropped up here and there among two or three varieties, and if a strain of this character could be worked up, it would mean much to the grower of these flowers under glass, as they were well in bloom three weeks in advance of any of the others (some twenty varieties).

CALCEOLARIA CLAREFIELD GEM.

A very graceful herbaceous calceolaria, carrying branching head of fair-sized golden, red-dotted flowers. A.M., R.H.S., May 20. Mrs. V. Litkie, Clarefield, Pinkney's Green, Maidenhead. See page 395.

Varieties for Glass Culture.

The question of varieties under glass is, if anything, more important than out of doors; last season I was very much impressed with the variety Annabelle Lee, and, after seeing it again this year, I should venture to say it is one of the very best under glass. The colour, rosy-lilac. Lady Miller was seen in good form early last year, but out of doors it disappointed me. After growing it, and seeing it growing under glass, I would strongly recommend anyone to give it a big share of the space at their disposal. It is aptly described as apricot on cream, with just sufficient pink in it to warrant it being termed cream-pink. The raiser, when discussing it late last autumn, said: "Man, it's the grandest pea you ever saw!" and I admit it—under glass.

In the brighter shades Inspector and Thomas Stevenson are good enough for anything, and they keep their colour well. With such varieties as these, the crimsons and scarlets are not wanted under glass, they appearing quite dull by the side of them. Ruby Palmer, a new variety, may prove an acquisition in this class, as it appears to be a self crimson without any sign of blue or magenta in it, which so many is very obnoxious. Melba, Barbara, and Stirling Stent are, of course, very fine, and it is simply a matter of choice which of these three or Inspector is grown. Mrs. Routzahn is another sweet pea in the pale shades which does well, and it certainly is deeper in colour under glass than out of doors, a point which should at once recommend it to growers.

There is not a great demand for flowers of a maroon colour, but the variety Brunette is so rich, and of such good form, that it should sell well, the red-maroon shade harmonising so well with some of the creams and cream-pinks when colour contrasts are desired. Elfrida Pearson, Doris Usher, and Hercules are so well known that it is quite unnecessary to more than mention their names, and either ought to satisfy the most exacting as a pink variety. New Marquis, Blue Picotee, and Mrs. McIlwrick are three new varieties that are worth noting.

Sweet Peas in the Open.

Sweet peas generally are growing well out of doors, and in many instances are stronger than usual, and what is wanted now is fairly warm and dry weather to steady them down a little. Staking, where not completed, should be pushed forward with all possible speed, also the thinning and regulating of the shoots (especially of autumn-sown plants) must be proceeded with, although this advice is hardly necessary to the sweet pea enthusiast, as in many instances this is done almost too soon. I defer it as long as possible to secure a good root action.

As mentioned, the plants are, in most cases, very strong, but the flower beds are not as early as in some seasons, and in very few collections will blooms open before the first week in June, at least where they were sown in October. Last season the first blooms out of doors were cut here on May 18, but I very much doubt if any will be fully open by the end of the month—the usual date being the 25th.

Market growers are taking the cultivation of sweet peas much more seriously than they were a few years ago, and it would not surprise me in the near future to see them on the market quite up to the best exhibition standard, and I might add that under better methods of cultivation they ought to be quite as remunerative, or even more so, than when grown on the old haphazard system. This change has been largely brought about by the many splendid exhibits that have been put up at the horticultural shows by our sweet pea specialists from time to time, thus emphasising the great amount of good that exhibitions do to the trade of this country.

THOMAS STEVENSON.

ASPARAGUS: ITS LITERARY AND CULINARY ASSOCIATIONS.

(Continued from page 332.)

Mode of Culture.

And now having taken the literary and culinary sides, I should like to give you the other side, viz., the cultivation of the plant for the market, its native habits, etc. Loudon, in his "Encyclopædia of Gardening," about 1835, gives us much interesting information on this score. He says that asparagus belongs to a class of esculents which may be considered as comparatively one of luxury. It occupies a large proportion of a gentleman's garden, often an eighth part, but enters sparingly into that of the cottager. A moist atmosphere is congenial to asparagus, which is a seashore plant. Asparagus officinalis, L. English botany, t. 339, Asphodeliæ, B.P. Asperge, French; Spargel, German; Aspergie, Dutch; Asparago or Sparagio, Italian; Esparrago, Spanish. It is a perennial plant, found in stony or gravelly situations near the sea, but not very common. It grows near Bristol, in the Isle of Portland, and sparingly in Seaton Links, near Edinburgh. The roots consist of many succulent round knobs, forming together a kind of tuber, from which numerous erect round stems arise, with alternate branches, sub-divided into alternate twigs, not unlike a larch fir tree in miniature. The leaves are very small, linear, and bristle-shaped, the flowers of a yellowish-green, and odorous, are produced from June to August, and the berries of a yellowish-red. The whole plant has a very elegant appearance. Many of the steppes in the South of Russia and in Poland are covered with this plant, which is there eaten by the horses and oxen as grass. It is cultivated, to a great extent, in the neighbourhood of Paris, and to a large size in the neighbourhood of Ulm and Augsburg, on the banks of the Danube, where the soil is a calcareous sand, three or four feet deep, and the subsoil always saturated with water. In the neighbourhood of London it is cultivated to a greater extent than anywhere else in the world, and chiefly at Deptford and Mortlake. Some growers at these places, and especially the latter, have above one hundred acres each. The most celebrated grower of that day (about 1835) was Grayson, of Mortlake, who produced shoots nearly half an inch in diameter.

Coming down to later times, we find that the cult flourishes in East Anglia, and amongst our greatest growers we may mention Mr. Harwood, of St. Peter's Street, Colchester. He generally carries first honours at the Royal Horticultural Society's Spring show, and treasures the memory that our late King Edward VII. so admired the exhibit at the Temple Show that the happy grower was sent for. Mr. Harwood is not only one of the greatest and most successful growers of the day, but also a raiser of new varieties. His plan is to grow the plants flat at first, and when they are two years old they are taken up and planted in the new bed. Soil, sandy loam, eighteen inches in depth over the plants. All asparagus beds should be well manured in November. Salt should not be used as it makes the earth cold, and tends to keep the asparagus back. Some bundles shown at the Temple Show weighed sixteen pounds, and were comprised of only one hundred heads. The best sorts to grow are Giant Reading, Connover's Colossal, Batavian, and Argenteuil.

In this country asparagus is frequently forced, but seldom with much success, the heads being usually small and stringy, without sufficient succulence. For this purpose an asparagus bed is dug up, and the plants transferred to a place heated with manure, where they come up in a fortnight or three weeks; but as the roots are always much injured by the operation of transplanting, the little success that attends this method is easily accounted for. In many parts of the North of Europe, especially about Riga, a far better mode is adopted. The forcing takes place in the asparagus beds themselves without disturbing the roots; the trenches are filled with the hot manure, and the beds are covered with the same material about six inches deep. If the weather is very severe the beds are also covered with frames, but this is rarely necessary in England. Treated thus, asparagus is as fine as if it waited till May to make its appearance. But when this method is practised the heads cannot be cut down at the natural time in the same season.

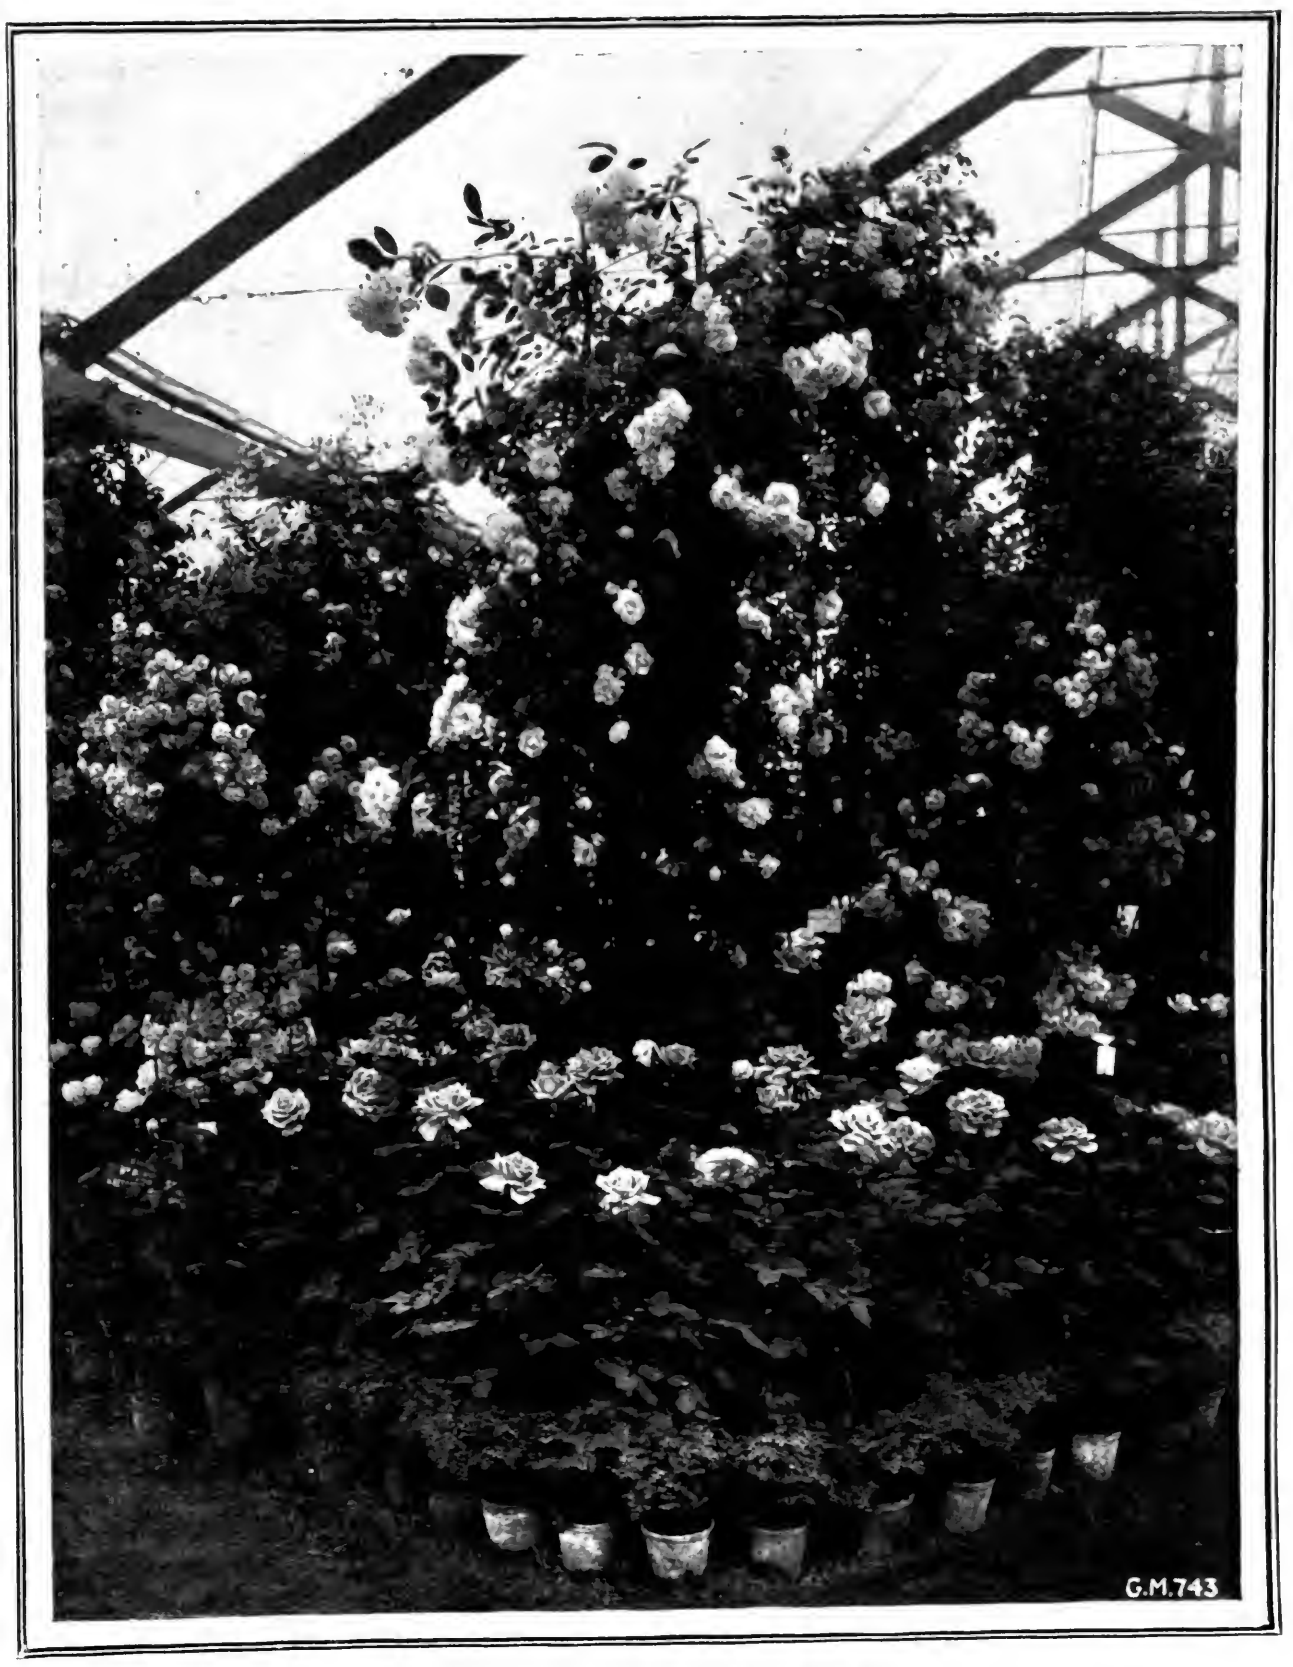
In order to recover from the effects of forcing the plants must be allowed to grow as freely as possible during the succeeding summer, so that they may form a new supply of food for the support of the heads of the succeeding spring. When it is wished to have exceedingly large heads of forced asparagus, pieces of bamboo, or any other hollow tubes, should be put over the shoots when they first make their appearance. The latter will acquire a length of eighteen inches without losing their tenderness.

H. C. Philbrick.

WORMIA BURBIDGEI.

An evergreen stove shrub well worthy of consideration for its foliage alone. The elliptic-shaped leaves are large, dark green, and of a stout leathery texture. The flowers are borne in an unbranched panicle, and are about three inches across; the colour is bright yellow. The individual blooms do not remain long in beauty. They are composed of five petals, and bear a somewhat close resemblance to some of the hibbertias; indeed, the wormia is a member of the same order, namely Dilleniaceæ. The specific name perpetuates the memory of the late Mr. F. W. Burbidge, so long identified with Trinity College Gardens, Dublin. In the years 1877 and 1878 he visited Borneo, the main object being the introduction of Nepenthes Rajah, which was successfully accomplished, while many new plants were found, notably this Wormia. It was first distributed in 1885.

K.



ROSE WHITE TAUSENDSCHON.

A pure white variety of the popular rose-coloured multiflora rose Tausendschon. A.M., R.H.S., May 20. Messrs. Wm. Paul and Son, Waltham Cross.

See page 393.

STORY OF A LOCAL PLUM.

If you happen to be passing along the Severn side in April, below Gloucester, where the river broadens out into an estuary, you may see on either side of the stream sloping hillsides and flat lands planted as orchards that are living masses of pearly white plum blossom. Should you happen to be in the same country again in August, you will see plum picking in full swing in the orchards. You will meet spring drays and carts laden with hampers of fruit, and at the station yards you will observe tons of plums from the Severn side being packed off to the mining valleys in South Wales, and the big manufacturing centres in the Midlands and the North. There will be nothing unique about either the first picture nor the latter, except that the plums in bloom in April are of a variety belonging to the Severn Vale, and at picking time you will probably find no fruit just like them in any other county in England.

The plum referred to is a local variety known as the Blaisdon Red, and, so far as I am aware, it is confined to the district where it has established itself, nor have I ever seen the name in any nurseryman's list. Yet in its own district the Blaisdon Red is the most profitable plum that is grown, taking one season with another. Intermingled with it you find Victorias, Prolifics, Czars, and the rest of the recognised commercial varieties, which occasionally bring in more money, but, taking the average of years, there is nothing pays like the Blaisdon Red, and the fruit-growers in the Vale of Severn are jealously proud of the plum, which they look upon as being peculiarly their own. As the name implies, the plum is red, not very large, and of prune shape, but it is excellent for preserving and cooking, it travels well, and will stand the wet of even a summer like the last without suffering much damage. In fact, it is just the plum for handling in big quantities for market supplies and meeting the requirements of the masses.

Propagation is not a difficult matter, for Blaisdon Red, like the Pershore of Worcestershire, grows on its own roots. Suckers are thrown up by fruiting trees very freely, and the latter are taken up and planted to make fresh orchards. The trees are grown entirely as standards, which have an upright habit, compact, yet bushy, and after young specimens have been cut back to form the head little or no pruning is required. The great point in favour of the Blaisdon Red is that if any variety bears this will, with the result that it is a very bad season indeed when there are no Blaisdons; and though in glut years they may be worth very little in comparison, still their reputation sells them in the South Welsh markets that are not far away, and in the heaviest of plum years there is probably as little waste with Blaisdons as in any other of the many plums that are now in cultivation.

Now the story of this local plum is quite an interesting one, and its establishment in the Severn Vale is within the memory of a few persons still living. Not long ago I was in a little village on the banks of the Severn, but on the opposite side of the river from the place where the Blaisdon Red originated. There I met an old gentleman, who claims the credit for being the first to bring Blaisdon Red across the river. He established an orchard of his own, which, he says, has paid better than any other piece of land on his farm during a fifty years' tenancy; but there are numerous other orchards in the village and district, all fruitful and profitable, while the cottagers and small occupiers, who mix up fruit-growing with salmon-fishing, look to Blaisdon Reds to help pay the rent. In fact, the introduction of Blaisdon Red from the other side of the river a good many years ago has gone a long way towards making this a fruit-growing district of some importance.

The old gentleman referred to had peculiar reasons for being interested in the plum under notice, for it originated in the garden of his parental home in the tiny little village of Blaisdon, on the outskirts of the Forest of Dean. Strangely enough, too, it was the death of an apricot that brought about the existence of the Blaisdon Red plum. This apricot occupied a place on a wall, and it displayed that bad habit of apricots of dying back, a branch at a time, until there was nothing left. Then out of the stock below the ground, upon which the apricot was no doubt originally worked, there sprang up a plum growth, which was allowed to remain and take the place of the old apricot. It was regarded as having a touch of novelty, but in course of time, when it fruited, the plums were found to be good. Other suckers came up, and were duly taken off and planted. There were not so many varieties of plums grown then as there are now. Nurseries were not so numerous, nor trees so cheap, so the folk about Blaisdon begged a few grafts from the original tree, which were freely given, and in this way, as well as from suckers, the variety became distributed, and became public property, as it were.

In telling this story, the old gentleman, who remembers the first Blaisdon Red tree and described the place where it grew, had only one regret, i.e., that his family did not keep the stock in their own hands, and plant every available inch of land they could get with it, for the purpose of establishing orchards. Had they done this they might have reaped a rich harvest before anyone else got a start; but it is easy to be wise after the event, and they did not know the treasure they had in the variety that Nature presented to them.

On the other hand, the accidental introduction of the Blaisdon Red plum has added considerably to the fruit-growing wealth of a district and a community of growers. Had the old root of the disappointing apricot been grubbed out, as it well might have been, the Blaisdon Red plum would never have originated, and without it the locality where it is now grown so largely might never have been a plum-growing district at all. Further, from a financial standpoint, hundreds of pounds that have gone into the pockets of fruit-growers in the Vale of Severn and round about would never have found their way there if an apricot tree in an old-fashioned country garden had not died back and sent up a plum sucker from its stock below the ground. Such, then, is the story of Blaisdon Red, the best all-round plum that is at present grown in the Vale of the Severn. H.

LABOUR AND WAGES.

I was much interested in the remarks made by Mr. James Day on page 188 with reference to work and wages, as this is one of the greatest worries that gardeners have to contend with in many places in the rural districts, for there are few classes of labour so ill paid as that of the garden labourer. Farm labourers in many instances (I know from personal experience) are far better paid than the men who work in the gardens, as they are able to earn extra money at various times of the year by what is termed piece work. As an example, a good hedger will earn from £1 to 25s. a week during the short days in winter, and the same may be said of a hay trusser; while in the summer time much of the work in many places is done by the piece.

Garden men have no such privileges; their wage is the same the whole year round, from 14s. to 16s. per week, out of which they have to pay 2s. 6d. or 3s. 6d. for rent. If there are any labourers who deserve an increase in wages, they are the garden labourers. Their work at times is by no means easy; digging, for instance, for weeks together. Mowing and such like, is quite as trying as much of the work for which a much higher wage is paid. Every gardener in the rural districts knows full well the difficulty he has in procuring suitable men, especially in places where the hours of labour are from six in the morning to six at night, with no short time on Saturdays. Young, strong men prefer to go to towns where the hours are shorter and they have their Saturday afternoons to themselves.

It is now very difficult to obtain young men to work in the houses, as few intelligent, smart young fellows care to be tied in the way they are, and lead such a monotonous life as falls to the lot of many in some of the out-of-the-way places. True the case is somewhat altered since bicycles have come within the reach of most people, but during the winter season the roads are bad, so that it is difficult to get about on them. When young men of the present day apply for a situation they usually enquire the hours of labour, if there is any Sunday duty, and if so, was it paid for. Also whether there is half-day on Saturday, how much holiday is allowed, etc.; and if they find such things are not in accordance with their views they at once decline the place, or, if they accept are not satisfied, and are soon gone again, knowing full well they can obtain higher wages with less restrictions in gardens that are within a comparatively short distance of towns.

Gardeners in such places are put to great disadvantage, not being able to procure the pick of men as they should be able to do where a more generous scale of wages is provided. If employers would take into consideration that it was to their interest to assist the young men by providing them with books and papers, also by having a suitable room in the village where they could meet and enjoy themselves, there would be an immense improvement. In the rural districts houses in many instances are very scattered, and there is no meeting-place except the village inn, which is by no means an ideal spot either for convivial gatherings or for raising the status of a young gardener or improving his knowledge. Near towns the case is quite different, as there are usually all kinds of amusements and entertainments going on, where the young can go and enjoy themselves, or where those who are more studiously inclined can attend suitable technical classes and so improve their knowledge in many and varied subjects. The wages men receive in the rural districts will not admit of many luxuries of this kind; even where young men are disposed to follow a studious career, they have great difficulty in obtaining the necessary books to enable them to do so, and unless a man has a superior knowledge of the business or profession he is called upon to follow he cannot hope to reach the goal of his ambitions. H. C. PRINSEP.

EXHIBITIONS AND MEETINGS.

GREAT FLOWER SHOW AT CHELSEA.

(Concluded from page 385.)

ROCK AND FORMAL GARDENS.

Planted out in beds, with grass walks between them, the azaleas, acers, rhododendrons, and other flowering and ornamental subjects, shown by Messrs. J. Cheal and Sons, Crawley, produced a surprisingly beautiful effect, the splendid condition of the plants and the taste evinced in their arrangement being worthy of the high reputation enjoyed by the firm. From this point in the exhibit a paved pathway led one into a garden of the old English type, with its imitation well in the centre, and beds ding plants, edged with lavender. Out of this restful enclosure a paved pathway led on to feature number three, which was a tastefully-arranged rock garden, made of a calcareous stone from Swanage, which only wanted a bit more weathering to make it look quite in keeping with the hardy primulas and other plants that filled the crevices. The Crawley's firm's exhibit did not enjoy the best of positions, but few people missed it, and all who saw it added their meed of praise.

It is by no means uncomplimentary to any other exhibitor to say that the most natural looking rock garden in the show was that arranged by Mr. J. Wood, of Boston Spa, Yorks. It was truly a rock garden, nothing else but rock and water; and, as you looked at it, you felt that instead of being brought all the way from Yorkshire, Nature had put the stones there, thrown them up by some upheaval in the past, and left the craggy points in some places, and the edges of the strata emerging from the ground in others. You could also imagine that the rocks had been weathered and washed where they lay by the storms of passing generations, leaving just enough soil in the pockets and crevices for the pretty little alpines to grow in. In reference to the latter, there was nothing out of the ordinary, but every clump of plants was in its right place, looking as if they had grown there from the days of infancy. There was a suspicion of newness about the rockery set up by Messrs. T. S. Ware, Feltham, but otherwise it was attractive, and the big patches of aubrietias, azaleas, and violas made a good display, and the semi-aquatic plants round the edges of the ornamental pool in the centre looked quite at home.

Enormous were the stones used by Messrs. J. Piper and Sons, Bayswater, in the formation of their rock and water garden, but what is more to the point, they arranged them to such good effect that they looked as if they had occupied their positions for years. Even the London sparrows seemed quite at home as they hopped from stone to stone. A very natural-looking pool that twisted in and out was crossed by stepping-stones, and a paved way led up to a stone seat, set, as it were, in the side of a face of rock. Water trickled musically down a cascade, and lost itself in the pool below. In the crevices between the stones grew, or seemed to grow, batches of suitable plants, and in the sunlight the colours of crimson primulas were reflected in the water. At one point an ornamental purple wistaria drooped over the pool, at another a white one; while at one corner there was a compact little representation of a bog garden that seemed to have been dropped in just the right place.

Enclosed by a yew hedge and paved with stones of all shapes, Mr. R. C. Notcutt, of Woodbridge, made a garden of hardy mollis and other azaleas and rhododendrons. The former, which filled a raised bed in the centre, were interspersed with Japanese maples, and the whole effect was very pleasing. Messrs. R. Tucker and Sons, Oxford, set up an arrangement of rockwork with the usual steps and paved ways. A batch of blue gentians at one corner was very pleasing, and popular rock plants were dispersed about.

ROCK GARDEN EXHIBIT AT CHELSEA.

Arranged by Mr. J. Wood, Boston Spa, who was awarded the gold medal. One of the most natural pieces of rock-work yet displayed.

Mr. Clarence Elliott, Six Hills, Stevenage, used his position to great advantage, skirting a low bank with easy rockwork, rendered gay by colonies of Primula sibirica, P. involucrata, Gentiana acaulis, iberis, aubrietias, and Daphne cneorum. On a rocky bed near by were saxifrages and sedums in the open sunshine, with aquilegias, anemones, and dwarf pines. On the larger, bolder part of this rock garden Mr. Elliott had a superb mass of the glorious blue Aquilegia glandulosa, carrying wonderful blooms on sturdy stems. Besides this we noted alpine phloxes, Saxifraga Stormonth Seedling, ramondias, and Viola gracilis. For the dainty little rose-red Pentstemon Davidsoni Mr. Elliott secured an A.M. Alpines of many kinds were exhibited by Messrs. Cunningham, Fraser, and Co., Comely Bank Nursery, Edinburgh, but the leading subjects were choice saxifrages, Pinus mughas, Schizocodon

Soldanelloides, the cushion-like Erica hypnoides, Haberlea rhodopensis, and Primula Littoniana. This group was on raised tabling out of doors, and was at a very convenient height for inspection.

The rockery from Messrs. J. Backhouse's Nursery at York struck one as being a representation of a bit of peak scenery, and there was a pleasingly natural look about the water that trickled down the cascade into the pool below. Here we saw gentians growing on a grassy bank, and a mixed bed of hardy flowering plants at one corner attracted attention.

A combination of paved garden and rock garden, with rocky walls sustaining narrow terraces, made up the exhibit from Mr. Maurice Prichard, Christchurch. The rock garden was in the centre with a paved path around and the walls beyond. On the terraces some of the most interesting plants were Œnothera ovata, Primula Cockburniana, Geum Mrs. Bradshaw, Oxalis enneaphylla rosea, Achillea herbarota, gleaming white; Primula japonica, P. pulverulenta, P. sibirica, and P. Bulleyana. On the rock garden proper Daphne cneorum, the rosy Dianthus Emile Parc, Gentiana acaulis, Phlox pilosa Brilliant, Veronica salicornoides tucked into crevices, Trollius pumilus, Silene Hookeri, Lewisia cotyledon, and L. Howelli. There appeared to be rather too many wooden labels showing on the rockery set up by Mr. G. Reuthe, of Keston, as they seemed to overwhelm the diminutive plants. The green moss, too, that was freely used, would hardly be found in anything but a temporary rock garden, and on this account the imitation of permanency was not a complete success.

A rustic bridge, a boggy kind of stream, a flower-studded bank behind, with a pathway leading up to it, were the features of the rock garden arranged by Messrs. W. Cutbush and Sons, Highgate. There was a cunningness about the device, and, without over-doing it, the material employed was used to good advantage. The Craven Nursery Company, Clapham, Yorks, was responsible for a small rockery, on one side of which blue gentians were conspicuous, and on the other a mass of white trilliums attracted attention.

TREES AND SHRUBS.

The choicer trees and shrubs, chiefly the flowering kinds, were grouped in the big tent, and the crowds that gathered round them indicated the interest these plants created.

In this section, Messrs. Jas. Veitch and Sons, Lim., Chelsea, had a grand group, which was made up chiefly of rhododendrons Pink Pearl, Doncaster, Mrs. E. C. Stirling, and Marchioness of Lansdowne. Hydrangeas Hortensia rosea and Madame M. Hamar were very fine, and the golden azaleas Anthony Koster, Nancy Water, and others gave a bright splash of colour that formed a contrast to the pink of the rhododendrons. The flatness of outline was broken by standard specimens of Styrax japonicum, Rosa hugonis, Cytisus Dallimorei, and other plants of more than passing interest. Though the group of hardy-flowering trees and shrubs, shown by Messrs. W. Paul and Son, Waltham Cross, was a little flat, the display was beautiful and striking, and the colours were pleasingly blended. Rhododendrons Pink Pearl, Lord Palmerston, and Sigismund Rücker made a bold centre, and around them were azaleas, lilacs, cytisuses, honeysuckles, and a host of other things.

Messrs. Geo. Jackman and Son, Woking, had a very interesting group of plants of hardy character, which included some fine specimens of Kalmia latifolia, Hydrangea arborescens grandiflora alba, Philadelphus aurea, and Viburnum plicatum, together with ivies in variety, and other flowering and foliage shrubs. A great display of rhododendrons was made by Messrs. Fletcher Brothers, Chertsey, who exhibited amongst other better-known varieties the following novelties: Duke of York, salmon pink; Helen Paul, pink; Profusion, of the same shade; and H. M. Arderne.

Messrs. Paul and Son, of Cheshunt, showed a group of hardy azaleas, in which Glory of Cheshunt, Milton, High Beech, Orange, and Freda Paul were conspicuous varieties. Mr. Chas. Turner, of Slough, sent a collection of lilacs that were hardly open enough to show to the best advantage. Amongst the varieties represented were Madame Lemoine, Charles, and Souvenir de L. Spath, Negro, and Arthur W. Paul.

Very bold and handsome were the great flat blooms of the finer clematises, shown on the growing plants by Messrs. Geo. Jackman and Sons, Woking. These were grouped with acers, palms, maples, and ferns. Fairy Queen, silvery-pink; Nellie Moser, rose and white; Lady Caroline Neville, pale blue; Lazarstern, deep blue, very large; Imperatrice Eugenie, pure white; and Jackmani rubra, deep red-purple, were just a few notable varieties in a fine group. Mr. Reuthe, Keston, showed a number of trusses of Himalayan rhododendrons, and the brilliant Embothrium coccineum, with other interesting flowering shrubs.

Perhaps the most attractive variety in the mass of rhododendrons shown by Messrs. J. Waterer and Sons, Bagshot, Surrey, was Alice, a lovely pink flower, but, Cynthia was also striking, and the same adjective describes Michael Waterer, Marquis of Waterford, and Mrs. E. C. Stirling. Messrs. W. and J. Brown, Stamford, set up a big mass of named varieties of lilac, along with dianthuses and other plants.

Messrs. J. Waterer and Sons, Bagshot, also had a collection of acers outside the tents, and near at hand Mr. L. R. Russell put up a fine group of cut ivies and other plants in tubs, and at another point the same firm set up a most striking collection of flowering trees and shrubs, intermixed with acers and other ornamental foliaged plants, with a little bed of the bright salvia Glory of Zurich close at hand. Messrs. Fromow and Sons, Chiswick, had a very large group of Japanese maples in the Elm Avenue, in which practically every type of these ornamental acers was represented.

Two great groups of Ghent and mollis azaleas did much credit to the skill and taste of Messrs. R. and G. Cuthbert, Southgate, who always show these fine shrubs so splendidly. Every plant was smothered in bloom, and the colours were gorgeous in all shades of orange, salmon, and brilliant pink, as well as all shades of yellow, from faintest cream up to brilliant gold. Anthony Koster, Mdme. Mayer, Alphonse Lavalle, Graciosa, Clara Butt, W. E. Gladstone, J. C. van Tol, Comte de Gomer, T. J. Seidel, and Ellen Cuthbert forms a very fine selection from the scores of beautiful varieties presented by the Southgate firm.

Flowering trees and shrubs, from Mr. R. C. Notcutt, Woodbridge, were greatly admired, and the group was rendered very attractive because of the free use made of standards of ceanothus, brooms of various kinds, etc. Lilacs formed the foundation of the group, but Philadelphus rosace, with very large single white flowers, salvias, the striking Fabiana imbricata, Cytisus Daisy Hill (cream and crimson), and Philadelphus Bouquet Blanc were a few other good things. Among the lilacs exhibited by Messrs. Paul and Son, Cheshunt, Philemon, Souv. de L. Thibaut, the double Marc Micheli, Charles, the very dark Chas. Joly, Belle de Nancy, and Doyen Keteleer were a very fine set; the flowers were cut and shown in vases, and were delightfully fragrant.

The group of ancient wistarias in fancy pots and tubs exhibited by Messrs. J. Piper and Son, Barnes and Bayswater, was a source of attraction to lovers of flowering trees and shrubs. The plants were all imported from Japan, and were evidence of the considerable variation obtained in both Wistaria sinensis and W. multijuga. In some of the specimens the old stocks were stout trunks many inches in diameter. The white W. brachybotrys was very lovely, and we were much interested in some of the bicoloured forms of the long-spiked W. multijuga, especially the one with quite large, rich mauve and soft lavender flowers (see illustration). Then there were slender-spiked purple forms and some of delicate pink. This was a novel display, rendered all the more interesting because of the Japanese ware pans in which the trees were growing. With Pink Pearl rhododendrons piled high in the centre, and bold groups of the blue Hydrangea Mariesi, Messrs. Wm. Cutbush and Son, Highgate, provided the chief points of a big and showy group. The new Hydrangea Mdme. Mouillère, Verbena Miss Willmott, standards of Cytisus Andreanus yellow arums, Mollis azaleas, heaths, and the white-tipped Silver Star araucaria were used to fill up between.

A goodly set of pigmy Japanese trees from Messrs. Barr and Sons, Covent Garden, showed how skilful training can bend cupressus, larches, maples, etc., into all kinds of shapes; storks, porches, gates, and other quaint devices were presented, and there were innumerable examples of the Fuji-yama design in Cupressus obtusa. There were tiny plants in wee little pots simulating old age, and giants 3ft. high with trunks gnarled with age and skill.

Messrs. W. Cutbush and Sons were responsible for a fine display of topiary work, and the fantastically-cut peacocks, ships fully-rigged, squirrels, cocks and hens, or both, not to mention a host of other queer-looking specimens in box and yew, looked as if they were enjoying quite vigorous health, in spite of all the clipping.

A number of clipped box trees, packed in hampers, which came from Mr. C. White, London, and stood near to the Embankment entrance, were not displayed to the best advantage, but in another big group, from the same firm, all sorts were admirably represented. Quite a bewildering variety of quaintly-cut yews and box, exhibited by Messrs. J. Piper and Sons, Bayswater, London, demonstrated the popularity of topiary work. The same firm also showed a number of trained bay trees in tubs.

STOVE PLANTS.

For leaf-colouring, brilliant or dainty, nothing can exceed the caladiums, and a goodly group, such as arranged by Messrs. J. Peed and Son, Norwood, is an asset to any show. The group was a big circular one, and the specimens were set up well among maidenhair ferns. Particularly fine were the examples of Excellent, with its white blotches on a crimson ground; Guil Mar, salmon-pink; Sir Julian Goldsmid, palest pink and green; Flamingo, red flushed over pink; Mikado, red, bronze, and green; Silver Queen, semi-transparent, white; and Scarlet Pimpernel, a glorious variety, with buff ground and rich red-scarlet centre and veins, a bold, pleasing group.

Stove plants were finely staged by Messrs. Jas. Veitch and Sons, Chelsea, and their group was notable for its fine crotons, anthuriums, alocasias, the bright Kalanchoe flammea, Medinilla magnifica, with pendant spikes, and the striking Gloriosa Rothschildeana. Orchids were freely used in this effective and handsome display.

A group of many-coloured foliaged plants grown in stove temperature was shown by Messrs. L. R. Russell, Richmond. Anthurium regale occupied a conspicuous position in the centre, and close at hand was a fine specimen plant of Dracæna Victoria. Some of the crotons in the group were beautifully coloured, particularly Reidi, Thompsoni, and Mrs. Iceton, and a small corner patch of the beady Nertera depressa in one corner attracted some attention. One novelty in the group was a flowering plant of Medinilla magnifica superbiens, and Bougainvillea Maud Chettleburgh was admired. The same firm also staged a collection of the newer varieties of caladiums.

GREENHOUSE PLANTS.

Although they were disposed in all parts of the great tent, and therefore lost something of their collective effectiveness, the greenhouse

plants formed a large and interesting section of the great show.

Of special interest was the contribution of insectivorous plants from Mr. Bruce, Chorlton-cum-Hardy, arranged in a delightful manner with green moss and ferns. The Sarracenias were the great feature, and of these there were about a hundred and fifty plants, representing about thirty species, varieties, and hybrids, ranging from the old and hardy S. purpurea to the new crimson-veined S. Brucei, which gained an A.M. S. Willmottæ, C. flava gigantea, S. Fieldi, S. Stevensi, S. Williamsi, S. Willisi, and S. Courti were in capital form, and very interesting and beautiful with their accompaniment of sundews and other bog plants. Very glowing was the bank of Salvia splendens Pride of Zurich, a mass of brilliant scarlet, disposed by Mr. R. L. Russell, Richmond. On the value of this plant for greenhouse or flower garden decoration there is no need to dwell. Messrs. H. B. May and Sons, Edmonton, displayed a selection of ivy-leaved pelargoniums and standard specimens of heliotrope, marguerites, salvias, fuchsias, etc.

and especially glowing among the zonal varieties were Harry James, Paul Crampel Improved, Scarlet Glow, Ryecroft Gem, R. C. Pulling, Will. Toinon, Queen, and Floris, all these having large blooms of orange or scarlet shades.

A collection of species, varieties, and hybrids of pelargoniums was submitted by Mr. J. Seden, gardener to Mrs. Rolls-Hoare, West Grinstead Park, Horsham; the old Scarlet Unique, Miss White, Prince of Orange, and Rollison's Unique were included in these fragrant-leaved kinds. Messrs. Carter Page and Co., London Wall, brought a selection of pæony and decorative dahlia flowers, as well as various annuals.

A wonderfully fine exhibit of greenhouse plants was made by Messrs. Jas. Veitch and Sons, Chelsea. They occupied two tables, and over the intervening space they carried six pairs of rafter-trained fuchsias with their flowers hanging overhead. Underneath these were gloxinias, a splendid selection of a fine strain of erect-flowering streptocarpuses, Cineraria Matador, C. hybrida with white, blue-tipped flowers, C. Feltham Beauty, C. Royal Blue, excellent; the new C. Sunrise, house calceolarias which did him very great credit, as the plants were admirably grown, and furnished with fine flowers. The scented-leaved pelargoniums shown by Mr. E. Beckett, gardener to the Hon. Vicary Gibbs, at Aldenham House, made up an interesting group of educational value.

Messrs. T. S. Ware, Lim., Feltham, suffered somewhat as a consequence of having to sandwich their tuberous-rooted begonias in between masses of orchids. They had fine flowers and a beautiful series of varieties, and the display would have looked far better if away among foliage plants, etc.

Bottle-brush plants as standards and bushes were conspicuous features in the interesting group of plants set up by Messrs. Stuart Low and Co., Bush Hill Park, but specimens of Acacia pulchella were also effective, and a tree that attracted much attention was the new Araucaria Silver Star. A little group of gerberas were very effective, and the deep blue of the hydrangeas contrasted pleasingly with other shades of colour round about. Speaking collectively, this was an exhibit in which very superior

CHELSEA SHOW—A FINE COLLECTION OF CALCEOLARIAS, CINERARIAS, GLOXINIAS, SCHIZANTHUSES, ETC.
Exhibited by Messrs. E. Webb and Sons, Wordsley.

One of the loveliest groups, and certainly one of the most brilliant, was composed entirely of calceolarias, and staged in a circular mound by Mr. Herbert, gardener to Mrs. Litkie, Clarefield, Pinkney's Green. The centre consisted of C. Clibrani, and the outer ring of intermediate varieties; but the great attraction was the elegant Clarefield Gem (A.M.), a free-flowering herbaceous variety of the most elegant habit, and carrying branched trusses of yellow, crimson-dotted flowers of good size and great beauty. This should be a grand greenhouse plant, and an immensely popular one.

A high conical mound of schizanthuses, built up by Mr. C. W. Lane, gardener to Mrs. Claude Barrett, Hatton Court, Castlethorpe, would have been a very solid mass were it not for the innate grace and beauty of this beautiful greenhouse plant. There were myriads of butterfly-like blooms ranging from white to dark purple, and with orchid-like blotchings in very many of the varieties. Mr. H. J. Jones, Lewisham, staged his show and zonal pelargoniums in the form of a huge bed, and, as the plants were of moderate size, they could be looked down upon. They produced a brilliant effect.

buff and blue; Calceolaria Clibrani and C. Buttercup, gerberas in variety, and a glorious lot of amaryllis, the graceful Elæocarpus reticulatus, and the yellowish Cineraria florescens. This exhibit met with great admiration. Streptocarpuses, finely selected, freely flowered, and arranged on a long bank, were from Messrs. John Peed and Son, Norwood; the plants showed a capital range of colouring, and the erect trusses carried the large blooms well above the foliage.

Messrs. Jarman and Co., Chard, were represented by a bank of cut zonal pelargoniums, a bank of Viola cornuta, and, of course, some blooms of the sweet and elegant sweet sultans—Bride, Bridesmaid, and Bridegroom. Calceolaria Veitchi and C. Bronze Age, which attracted so much attention a year ago, were again exhibited by the raisers, Messrs. Robert Veitch and Son, Exeter. Of C. Bronze Age they have now a brilliant crimson selection with yellow centre. C. Golden Glory was also presented.

Mr. Charles Turner, of Slough, put up a rather crowded group of show pelargoniums. Mr. Arthur Shambrook, gardener to the Rev. H. Buckston, Sutton-on-the-Hill, Derby, showed a group of green-quality predominated. Well-grown plants of show pelargoniums in named varieties were staged by Mr. J. W. Barks, gardener to A. P. Brandt, Esq., Bletchingly Castle, Surrey. The trusses were large, and, for a private gardener's exhibit, it was most creditable.

It is perhaps safe to say that Messrs. Blackmore and Langdon never staged a finer group of tuberous begonias. The massive double flowers were simply superb, some colours being delicate and others strikingly brilliant. One of the finest flowers in the group was the white Mrs. Peter Blair, but we also admired Princess Victoria Louise, and the baskets of Golden Shower and Lena, which gained an Award of Merit. Both individually and collectively the plants were of a wonderful standard of quality. A large number of trusses of single zonal pelargoniums were staged by Mr. V. Slade, of Taunton, the flowers being interspersed with suitable greenery. A very bright exhibit was set up by Messrs. Godfrey and Son, Exmouth, in which fancy pelargoniums and Veronica Hulkeana predominated.

A very pretty effect was made by Messrs. Cannell and Sons, Swanley, who showed some

ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER AND THE NORTHERN COUNTIES.
MANCHESTER ROSE, SUMMER SHOW, AND HORTICULTURAL TRADES EXHIBITION,
at the EXHIBITION BUILDINGS, RUSHOLME, MANCHESTER.
JULY 11th and 12th, 1913.
ROSES, SWEET PEAS, GROUPS, STOVE and GREENHOUSE PLANTS, CARNATIONS, BEGONIAS, Etc. A Good Prize List.
Schedules and all particulars from—P. WEATHERS, Sec., Botanical Gardens, Manchester.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

fine specimens of Calceolaria Clibrani, with masses of Schizanthus Wistonensis, show pelargoniums, and splendidly-grown florists' calceolarias, the whole making a showy exhibit. Pyramid azaleas are not often seen in these days at London shows, but Mr. Charles Turner, Slough, showed a few good specimens, trained in the once-popular conical form. There were also carnations in the group, and some ferns and acers. A few well and naturally-grown azaleas seemed to come in for more admiration than the trained specimens.

Messrs. Wells and Co., Merstham, had a small group of well-grown carnations in which White House, Triumph, etc., were well represented; their position was not a happy one, squeezed in between orchids and begonias.

Quite an effective collection of scented geraniums, in which a host of varieties were represented, was staged by Mr. E. Mitchell, gardener to Miss Troyte Bullock, Yeovil.

TULIPS.

These were a grand feature of the show. Tulips were boldly massed in a circular group by Messrs. R. H. Bath, Wisbech, and the attention paid these flowers was evidence of the growing popularity they enjoy. Gesneriana lutea, Parisian Yellow, Clara Butt, Baronne de la Tonnaye, Massenet, the deep red Rosalind, La Tulipe Noir, and Flava were a few outstanding varieties. A few pillar roses in the group and a circling band of violas added dignity to the display. In another group the same firm displayed tulips with dwarf roses, and stands of carnations. Mr. Christopher Bourne, Bletchley, presented well-grown tulips of the Darwin and cottage garden varieties, and John Ruskin, Goudvenk, Corydon, The Fawn, Erguste, Gesneriana lutea, Orange King, and Mrs. Moon were among the best.

Messrs. Barr and Son's display of tulips was a fine one, and the flowers looked very well in association with Japanese maples. This was a large display, and notably good were Mrs. Moon, Plutarch, Inglescombe Yellow, Margaret, the lovely pink and blush Edmee, Nauticus, Vitellina, and Columbus. The Wargrave Plant Farm, The Arcade, Liverpool Street, E.C., put up some capital flowers of popular varieties of cottage and Darwin tulips, and they had Fairy Queen in very fine condition. Messrs. Hogg and Robertson, Dublin, showed how fine tulips can be grown in Ireland, by staging a large collection of the best cottage and Darwin varieties of Inglescombe Yellow, Europa, Mrs. Moon, Clio, La Tulipe Noir, Inglescombe Pink, and May Queen; they had very handsome bunches.

Another tulip show was made by Messrs. Sutton and Sons, Reading, this firm setting up a sharply pitched bank of fulgens lutea, Black Chief, The Fawn, Louis XIV., Baronne de la Tonnaye, Inglescombe Yellow (very fine), Prince of Orange, Dom Pedro, Clara Butt, Lucifer, Iris, and the glowing scarlet Caledonia, a fine cottage tulip; there were other varieties, but these were the chief. Some superb tulips were set up by Messrs. Dobbie and Co., Edinburgh, and of Mrs. Moon, Picotee, Europe, Inglescombe Yellow, Margaret, Mrs. Farncombe Sanders, and Inglescombe Pink there were grand examples.

Quite a long length of tabling was occupied by the May-flowering tulips shown by Messrs. J. Veitch and Sons, Chelsea. The nearly black Darwin tulip Leonardo da Vinci was very much admired, as also were the Darwins Louise de la Vallière, Mr. F. Sanders, Suzon, and Clara Butt. Inglescombe Yellow was the finest of its colour in the collection, which was very choice all the way through. Messrs. Cartwright and Goodwin, Lim., Kidderminster, showed a pretty bank of tulips over a groundwork of Isolepis gracilis. A number of the best varieties were represented in flowers of moderate size.

The tulips from Messrs. A. Dickson and Son's Nursery, Belfast, were not only beautiful, but they had the merit of being very tastefully arranged. Amongst the varieties which attracted most attention were Sensation, Bartigon, Dom Pedro, Inglescombe Pink, The Fawn, Leghorn Bonnett, Orange King, Bacchus, Fashion, Clara Butt, Monument, Melicette, and Fairy Queen. The greatest credit is due to the Irish firm, not only for the wonderful variety displayed, but the admirable way in which each stand of flowers showed itself to advantage, and distinct from its neighbours. Judging from the remarks one heard in respect of these tulips, it is doubtful whether any exhibit in the show was more admired.

A circular group of May-flowering tulips, set up by Messrs. J. Jefferies and Son, Cirencester, was much admired. Grown at a high elevation on the Cotswold Hills, the flowers were very fresh, the stalks long, and the colours brilliant. Europa, a scarlet form, attracted much attention, as also did Blue Flag, but a very large number of varieties of these beautiful and popular tulips were represented. Mr. C. W. Needham, Hale, Cheshire, showed a collection of tulips that were interesting in their variety, but would have been more effective if they had been staged better. Messrs. Barrie and Brown, London Bridge, showed a small and rather crowded collection of tulips and roses with some quaint little specimens of the old-fashioned house leek.

SWEET PEAS.

These are now one of the features of the great spring shows, and at Chelsea they were splendidly shown.

Plants in pots, carrying lovely flowers, were used by Messrs. Dobbie and Co., Edinburgh, to form a background to several dozen bunches of very delightful flowers set in glass vases. In colouring the blooms were in some cases even brighter than in July. Such varieties as Thos. Stevenson, Rosabelle, Mark's Tey, Chas. Foster, May Campbell, Decorator, Lavender George Herbert, Mrs. Cuthbertson, Inspector, Brunette, and Dobbie's Scarlet, were of exceptional merit. The spikes were full-sized, and carried big, cleam blooms of great beauty. The new Ruby Palmer, a rich red, was among the novelties. Messrs. Sutton and Sons, Reading, had secured long stems to their spikes of sweet peas, and they put up an attractive display of Moneymaker, Mrs. Heslington, Barbara, Doris Usher, Mrs. W. J. Unwin, Mrs. C. W. Beardmore, King Manoel, and Lady Evelyn Eyre.

The sweet peas from Messrs. E. W. King and Co., Coggeshall were in fine form, and staged to make up an interesting and pretty exhibit. Here we noted Anglian Orange in lovely colour; Hercules, Anglian Crimson, Anglian Pink, the new claret-red and rose-coloured Anglian Royalty, and new bicolor, Thos. Stevenson, Prince George and Queen Mary. Miss Hemus, Upton-on-Severn, showed sweet peas in association with petunias, poppies, etc.

Another contribution of sweet peas was made by Mr. Robert Sydenham, Birmingham, and the varieties prominent in this group were Maud Holmes, Apple Blossom Spencer, R. F. Felton, Barbara, rich salmon-orange; Princess Mary, blue; Lilian, and Cerise Spencer.

FRUIT.

Provided with space to show off their exhibits to better advantage than ever they could at the Temple, the fruit people added a feature of great interest to the show.

As good as ever is the term which describes the fruit trees in pots from Messrs. T. Rivers and Son, Sawbridgeworth. Rich in colour were the fruits of the Cardinal nectarine, and equally attractive were the peaches, which included Peregrine and Early Alfred. The foliage on every specimen was deeply green, and perhaps it was this that made the fruits of Knight's Early Black Cherry look even more deeply black than the name implies. Early Rivers plums were there, thickly hanging on pot trees, as well as the Stint and Bluerock, and hidden away under a canopy of foliage was a basket of fine specimens of the Apple Buckingham. The same firm also exhibited a very interesting collection of oranges and citrons. From the King's Acre Nursery Company, Hereford, there came a group of fruit trees in pots, all of which bore the mark of robust health. Particularly attractive were the cordon gooseberry, Bluerock plums covered with fruit, Duke of York peaches, Early Prolific plums, and a variety of apples and pears.

The way that apples and pears can be kept was again demonstrated by Messrs. George Bunyard, of Maidstone, who showed a number of dishes of firm, crisp-looking specimens, amongst which we noticed Annie Elizabeth, King of Tompkins County, Newman's Pippin, Alfriston, and other well-known apples, as well as enormous specimens of that familiar pear Uvedale's St. Germain. Messrs. Laxton Brothers, Bedford, are to be congratulated, not only on what they showed, but the way their exhibit was arranged. There were arches of loganberries, fruiting plants of the Phenomenal berry, peaches and nectarines, and gooseberries and currants in pots, as well as the Laxton berry and tempting-looking fruits of the latest of Messrs. Laxton's strawberry introductions King George and The Earl. The deep crimson colour of the latter fruit is very pleasing.

VEGETABLES.

Though vegetables were not largely displayed, the quality was quite up to Temple Show form. Near to one of the entrances to the great tent Messrs. Jas. Carter and Co., Raynes Park, set up a collection of the modern style which is now so well known. Amongst other things we noticed Early Morn peas, and Carter's Early Duke, Improved Longswood dwarf beans, Seville Giant Long-pod broad beans, Solid Ivory and Standard Bearer celery, along with fresh-looking cabbages, lettuces, cauliflowers, vegetable marrows, tomatoes, and new potatoes.

Messrs. Sutton and Sons, Reading, made a very fine display with vegetables. The centre-piece was Sutton's Superlative French beans in pots, and flanking on either side were mushrooms in boxes in a natural growing state, the finest of Early Giant peas, Late Queen broccoli, neat little White Bush vegetable marrows, Eclipse tomatoes, Scarlet Horn carrots, Telegraph cucumbers, and numerous other dishes. To say that the exhibit from beginning to end bore the Sutton stamp of quality means to say that it was first-class.

A very tasteful exhibit of forced vegetables came from the Thatcham Fruit and Flower Farm, Newbury.

It would be impossible to speak too highly of the magnificent collection of vegetables set up by that renowned grower, Mr. E. Beckett, of Aldenham House Gardens. In front of a background of a green shade were perfect specimens of cauliflower, vegetable marrows, Sutton's Perfection, Ideal lettuces, Long Purple fruits of the egg plant, and the greenest of peas. On stands along the tabling were fresh mushrooms, Pen-y-byd vegetable marrows, Quite Content peas, turnips, asparagus, tomatoes, red and yellow, potatoes, radishes, carrots, and broad beans. Everything showed signs of splendid cultivation, and the staging left nothing to be desired.

Some very fine sticks of rhubarb were shown by Mr. T. E. Davies, Syderstone, Norfolk.

AWARDS.

The following additional awards were made by the council of the R.H.S. after we had gone to press:

R.H.S. Silver-gilt Cup.—To Messrs. Wallace and Co., Colchester, for a herbaceous group.

R.H.S. Large Silver Cup.—To Mr. A. Dutton, Iver, Bucks, for carnations; to Messrs. John Peed and Son, West Norwood, for caladiums and flowering plants.

R.H.S. Standard Cup.—To Dr. John MacWatt, Duns, for primulas; and to Mrs. Litkie (gardener, Mr. Hulbert), Maidenhead, for herbaceous calceolarias.

SUNDRIES.

Interesting, perhaps, only to the really practical gardeners who visited the show, but nevertheless of real importance and utility, were the extremely varied articles and preparations, embraced by that comprehensive term, "horticultural sundries," which occupied a considerable amount of space, both in the tent and out of doors. The greater proportion of the exhibits were such as we have seen many times before, but such is the almost feverish energy and enterprise of present-day trade that nearly every exhibitor had something fresh to show, and an hour or two was profitably spent in examining and discussing the tools, chemical preparations, and aids to successful culture displayed in great profusion. One of the first things to attract our attention

INSIDE THE TENT

was an implement shown by Messrs. Corry and Co., Lim., Bedford Chambers, Covent Garden, W.C., which they call Vesey's Patent Universal Spreader. The article may be described as a metal hopper on wheels, with a revolving discharger at its base, through which fertilisers, seeds, lime, or sand can be rapidly and evenly distributed over lawns, golf courses, or similar places. This is a machine of undoubted usefulness, and is very easily used. Messrs. Cory had a range of chemical preparations, tools, and requisites suggestive of the extent and importance of their business as wholesale distributors of everything for use in the garden.

Another well-devised machine of great utility to the seed trade is the Reliance seed-packet filler, exhibited by Messrs. Blake and Mackenzie, Islington, Liverpool. By easy manipulation this machine can be so precisely adjusted as to convey to a seed packet an exact quantity of any kind of seed. The Simplicitas Seed-Tester was another important item in Messrs. Blake and Mackenzie's exhibit. A metal tank, filled with square, brick-like blocks, upon which the seeds are placed, may be warmed by either gas or oil lamps, and with the water kept at a temperature of about 70 deg., seeds germinate very rapidly. Mr. John Pinches, 3, Crown Buildings, Crown Street, Camberwell, showed the well-known Acme labels, a variety of plant supports, and metal exhibition tubes, and also a novel little sprayer attachable to any ordinary bottle.

The Four Oaks Spraying Machine Company, Sutton Coldfield, had a large stand inside the tent, and another in the open, upon both of which were shown a great variety of syringes, spraying machines, and garden cutlery. A novelty on their stand was a water can that is convertible into a spraying machine. Messrs. H. Pattison and Co., Greyhound Lane, Streatham, showed their lawn boots, and a strongly-made turf cutter for boring holes for insertion of tennis net posts, etc.

Messrs. Robinson Bros., Lim., Ryder's Green, West Bromwich, were occupants of a large stand, on which were seen Alpha pneumatic spraying machines, and an assortment of insecticides, Carmona fertilisers, and weed-killers. The British and Foreign Fibre Company, Glengall Road, Millwall, showed coco-nut fibre of excellent quality, which may well be called an everyday requisite in any large garden. The Acme Chemical Company, Lim., Tonbridge, Kent, had on view their weed-killers and arsenate of lead for spraying purposes.

The Key Fertilizer Company, Starling Place, Norwich, brought a lawn fertilizer, which they claim will rapidly convert rough, coarse grass into fine, close-growing turf. Samples of turf exhibited bore testimony to the beneficial effects of treatment with the fertilizer. Messrs. Wakeley Bros., Lim., Bankside, London, showed their specially-treated hop manure, which has frequently been mentioned in our pages as a most excellent manure for roses, fruit, or vegetables. Messrs. W. Voss and Co., Lim., showed their Creol Soil Steriliser, and seedling plants, grown in both sterilised and unsterilised soil.

Abol syringes, spraying machines, and insecticides were attractively displayed by Messrs. E. A. White, Lim., Paddock Wood, Kent, and their interesting booklet, "Steps to a Perfect Garden," proved interesting to a host of visitors. Another stand of chemical preparations, useful syringes, and other appliances came from the Boundary Chemical Company, Cranmer Street, Liverpool. The Kilm weed eradicator on this stand commended itself to us as a distinctly useful little instrument for dealing with plantains, daisies, etc., on lawns. Messrs. Joseph Bentley, Lim., Barrow-on-Humber, Hull, were represented by a display of sample tins and canisters of their familiar specialities, and on another stand Jeyes' Winter Wash, handy little sprayers, and syringes were shown.

One of the most remarkable of the exhibits in the whole section was the scientific display of germinating seeds, and microscopic examples of plant diseases, arranged by Messrs. James Carter and Co., Raynes Park. The seed-testing machines which were recently described in our columns were shown with a whole range of young seedlings in active growth, and a large number of powerful microscopes were set up, with slides of much interest.

The Gardeners Magazine had a large stand, upon which not only the paper itself, but a large selection of fine illustrations that have appeared in past issues, were exhibited, together with the various books on important horticultural subjects, published by Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C. Our sister paper, "Amateur Gardening," was represented by specimens of its coloured plates, and the process by which these are produced was demonstrated by examples of the first, second, and third printings, shown in conjunction with the original water-colour drawings.

The Chase Continuous Cloche was staged by the Three C.'s Company, Dale Street, Liverpool, there being, in addition to the original ridge pattern, a square protector, designed for covering small alpine and rock plants. Messrs. J. Weeks and Co., horticultural Builders, 72, Victoria Street, Westminster, S.W., had models of their well-constructed houses, and the well-known Duplex tubular boiler, as well as a section of a greenhouse roof, showing method of construction and making joints at ridge and eaves.

Lawn mowers were displayed on an elaborate stand by Messrs. Ransomes, Sims, and Jefferies, Lim., Ipswich, and also by Messrs. A. Shanks and Son, Lim., Arbroath, the latter firm's big horse machine being a powerful implement eminently adapted for use on broad expanses of grass.

OUTDOOR EXHIBITS.

Chief among the several firms showing ladders were the well-known Patent Safety Ladder Company, Peterborough, who showed their very handy and easily portable ladders that combine strength and adaptability to all needs of the gardener, with neatness and smart appearance.

Messrs. Chas. P. Kinnell and Co., Lim., Southwark Street, London, S.E., showed greenhouse boilers suitable for heating either a small amateur's house or an extensive range of forcing houses. Their "Charm" boiler is a circular upright, the Horseshoe is the favourite pattern with thousands who have a moderate amount of piping to heat, whilst the Anglian sectional, and Bisson horizontal tubular are obtainable in sizes equal to the largest requirements. A power-driven pump in action was another item of Messrs. Kinnell's exhibit, and with the fascination inseparable from working machinery this proved a great attraction to many of the gardeners present.

Messrs. Houtsch and Co., the Continental firm whose English headquarters are at Guildford, showed their peculiarly constructed boiler, the interior of which is divided into sections so arranged that the heat of the fire passes to and fro between water-filled bars five times before escaping. Messrs. Fenlon and Son, Tudor Street, E.C., showed their useful little heating apparatus which may be worked by gas or oil stoves. They also had a model greenhouse. Messrs. Skinner, Board, and Co., Bristol, had glass-houses built on their patent wire extension principle. The distinguishing feature of these houses is that wooden rafters and putty glazing are replaced by wire strands and metal clips.

Messrs. W. Duncan Tucker and Son, Lim., Cannon Street, London, E.C., exhibited capitally built greenhouses and very serviceable frames. Their span-roofed frames were especially good in regard to the manner in which the lights could be raised and fixed at any angle, either for purposes of access or for ventilation. Boilers of good workmanship were also shown by this firm. Messrs. Barford and Perkins, Peterborough, showed lawn mowers of several sizes.

Spraying machines, syringes, hand-pumps, etc., were largely shown by several firms. Messrs. Hartjen and Co., Noble Street, London, E.C., had their "Holder" pneumatic knapsack sprayers, and also the smaller and very useful hand-spraying machines which we recently described in our columns.

Messrs. Wm. Wood and Son, Lim., Wood Green, N., arranged an exhibit that may well be described as unusual in extent, as well as exceptional in variety of interest and high quality. One walked around from one object to another over old flagstone paths that, although newly laid, bore resemblance to time-worn paving in the grounds of an ancient abbey. Rose screens, pergola, and gateways surrounded garden lounges and chairs that invited repose, whilst appealing to artistic taste, and the thatched shelters and tea houses were finely done.

SPECIAL AWARDS TO HORTICULTURAL SUNDRIES AFTER TRIAL.

Award of Merit.—The Boundary Chemical Co., Cranmer Street, Liverpool, for Demon Continuous Spray Bucket Syringe; to Messrs. Cooper and Co., 24, Christopher Street, E.C., for Continuous Pump Knapsack Sprayer "Eclair No. 1"; to Messrs. Cooper and Co., 24, Christopher Street, E.C., for Continuous Pump Knapsack Sprayer "Etame"; to Four Oaks Spraying Machine Co., Sutton Coldfield, for Four Oaks Undentable Syringe; to Messrs. T. Green and Sons, Southwark Street, E.C., for 12in. "Silens Messor" lawn mower; to Messrs. T. Green and Sons, for 12in. "Silens Messor" lawn mower, with close-cutting blade for putting and bowling green; to Messrs. E. A. White, Lim., Paddock Wood, for "Abol" syringe; to Messrs. E. A. White, Lim., Paddock Wood, for "Abol" Continuous Knapsack Sprayer.

Highly Commended.—To the Alpha Extinguisher Co., Lim., Hereford, for Alpha hand diffuser; to Messrs. A. J. Barbour and Co., Leeds, for Watson's lawn sand; to Messrs. Barr and Sons, Covent Garden, for bulb planter; to Messrs. Corry and Co., Bedford Chambers, Covent Garden, for Tenax Grafting Wax; to Four Oaks Spraying Machine Co., Sutton Coldfield, for Four Oaks Centre Knapsack Pump, Four Oaks Large Continuous-pumping Battle Sprayer, Four Oaks nozzles; to Messrs. Hartjen and Co., 35, Noble Street, E.C., for Hartjen Battery Fillers and Holders; to Messrs. Headly and Edwards, for Through Water Way Garden Hose Reels; to Mr. V. T. Hill, Langford, for V.T.H. Patent Slug Traps; to Messrs. Lloyd, Lawrence, and Co., Worship Street, E.C., for Pennsylvania Lawn Cleaner; to Messrs. Skinner Board, and Co., Bristol, for Board's Patent Wire Tension Greenhouse; to Messrs. W. Voss and Co., Millwall, for Voss's Naptha Nicotyl; to Messrs. Wood and Sons, Wood Green, for square garden house with bamboo screen lining.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

CYMBIDIUMS.—Plants of C. Lowianum, which have been recently in flower, and those plants that still retain their flower scapes, should have attention, for any repotting that may be necessary should be done as soon as the flower scapes have been removed. Most cymbidiums, and C. Lowianum in particular, should not be disturbed at the roots more frequently than is absolutely necessary. About every third year will be ample. This being the case, some consideration should be given to the quality of the potting compost, as only materials of a lasting character should be used. We find a compost consisting of equal portions of fibrous loam and peat, with sufficient silver sand and finely-broken crocks to render the compost porous, the most suitable. This should be firmly pressed, and the surface be covered with a layer of chopped sphagnum moss, which will add to the appearance of the plant when in full growth. The size of the pots should be proportionate to the vigour and size of the plants. Ample drainage is necessary, as, in addition to the plants remaining in the same pot for a long period, they require a liberal supply of root moisture during the greater part of the year. Freshpotted plants must be carefully shaded from direct sunshine and bright light after repotting. The atmosphere should also be maintained in a humid state, and they will be benefited by a syringing overhead, whenever the outside conditions are favourable. Other species that have recently been in flower, or are passing out of bloom, may also receive attention. The hybrids are too numerous to enumerate, but they are now so plentifully distributed in collections and gardens generally that the merits of the different kinds for decorative and house furnishing effects will be understood. Finely-flowered plants of C. Lowianum and its hybrids are most useful, the lasting qualities of the flowers, even when cut, rendering them in every way desirable.

LYCASTE DIPPEI, L. plana, L. aromatica, and other late spring-flowering kinds must also have attention. If the plants have been rested in a cool, reasonably-dry atmosphere, they will now be producing their flower buds These also should not be disturbed by being repotted more frequently than is absolutely necessary. Any repotting required should be done before the new growth is far advanced, for if left until after flowering, it is not beneficial. The new growth will then have become so far advanced as to incur the risk of it receiving a check.—H. J. CHAPMAN, Oakwood Gardens.

CONSERVATORY AND GREENHOUSE.

CALCEOLARIAS.—Seeds should be sown now for raising plants for flowering next year. To grow calceolarias to a high degree of perfection they must not experience a severe check, therefore, sow the seeds thinly, so that when the young plants are lifted it may be done without disturbing the roots to any great extent. Sow in shallow pans filled with finely-sifted soil, made fairly firm. The compost should be composed of loam, leaf-soil, and sand. Place the pans in a cool, moist part of the greenhouse, and keep them shaded and covered with a sheet of glass till the seedlings are through. When large enough pot them singly, using thumb pots, and keep them in a cool house, and shade them at all times from bright sun. Shift them on before the roots become pot-bound, and grow them under cool conditions at all times. Calceolarias Clibrani and Veitchi make a pleasing contrast to the large-flowered kinds, and are likely to become quite as popular when better known. The plants should be lightly fumigated occasionally to keep them free from aphis.

PELARGONIUMS.—The plants for winter flowering may now be placed out of doors in an exposed situation. Attend to the stopping of the growths regularly, so as to encourage a dwarf, bushy habit. When well rooted they must be supplied with liquid manure and soot water, supplementing this occasionally with Clay's Fertilizer, which is admirably adapted to their requirements. Baskets may now be made up of ivy-leaved pelargoniums, these being very useful for the conservatory during the late summer and autumn months.

CYCLAMEN. — The young plants should now be sufficiently advanced to receive their final shift, which should be into 5in. pots. The compost must be carefully prepared, and be neither too wet or too dry when used. Good fibrous loam, leaf-soil, which has rotted naturally, a little dried sheep manure, and old brick rubble, finely broken up, form an excellent rooting medium for these. Brick rubble is also of much value as drainage for the pots, as the roots quickly take possession of it. The pots should be plunged to their rims in ashes near to the glass in cold frames. They must be carefully watered for some weeks after potting, and sprayed with rain-water several times daily during hot weather. Shade from bright sun, and ventilate the frames carefully, especially when cold winds prevail. Later on, when the plants are well established, the lights may be entirely removed in the evening, when the weather is warm.—E. HARRISS, Lockinge Park Gardens.

HARDY FRUITS.

MORELLO CHERRIES.—The management of trees when trained fanshape is very similar to that pursued with the peach and nectarine, and to procure regular crops of large fruits, every attention must be given at the right time. At present the branches are a mass of strong bloom, which promises well, should the weather prove favourable for a heavy crop when sufficiently advanced. Disbudding of the superfluous shoots, and selecting next year's fruiting wood, must be sedulously carried out, and all main leaders will need to be neatly secured to the walls or wires before they are injured by winds. Endeavour, as far as possible, to keep the walls clothed with healthy, fruitful wood, nothing being more unsightly and unprofitable than long, bare branches with only a few fruiting shoots at the top. To replace these there should always be ample new wood springing up from the base, forming, as it were, a continual succession of healthy branches. Keep the foliage and tips of the young shoots free from black aphis and other insect pests, so that the growth may not be crippled.

FRUIT TREES that were late planted should be watched carefully, and watered if needed, nothing being more harmful to late-planted trees than dryness at a time when new growth is being made. Keep a watchful eye on the new growths, and train them as desired to form well-balanced heads. Orchard trees must not be overlooked, and, if necessary, mulch early to encourage free growth, and the same remarks apply to trees that were lifted and root-pruned late in spring. Examine the soil about the base of the stems, and, if parted from the tree, slightly lighten the surface, and then tread the soil firmly. Keep all ties in good order to protect the bark from injury, and see that all the trees are correctly labelled.

GRAFTS.—Examine carefully those grafts which have taken and are growing away freely, and if the binding material is found to be too tight, remove it, and, if necessary, rebind with damp raffia. Damp at intervals the clay on late-grafted stocks, and fill up any cracks which have occurred. Make secure against storms the grafts that have taken, and where the binding material has been removed, or they may be blown off. Horizontally-trained pear trees, on which the grafts have failed to take, should have fresh young wood laid in, and at the proper time be budded. This I have practised with good results. Spray the leaves of pears and apples, if attacked by leaf fungus (Entomosporium maculatum) with Bordeaux mixture, or some other approved, safe, and reliable mixture recommended for that purpose.—H. MARKHAM, Wrotham Park, Barnet.

ANSWERS TO CORRESPONDENTS.

GREEN-HEARTED RANUNCULUS.—G. B., Dublin: Please let me know through your columns why the ranunculuses enclosed have green hearts.—All highly-bred florists' flowers have a tendency to revert to the ancestral type, and, remembering that petals of flowers are but specially-formed and coloured leaves, it is easy to see that the green petals in the centre of the ranunculus blooms are evidence of this power of reversion. In this case a very rich soil, and especially favourable conditions, followed by some check, such as changing temperature, may have caused the flower to take the easier course, and produce green, instead of coloured petals in the centre.

INJURED VINE LEAVES.—J. B., Tiverton: Kindly refer to an answer concerning vine leaves, that appears in this column.

GOOSEBERRY MILDEW.—W. A.: I enclose some gooseberry shoots that are badly infested with green aphis, but have also a white fungoid growth on them. Is the latter American Gooseberry Mildew?—Yes, the fungus on the shoots is American Gooseberry Mildew, a disease that must be at once notified to the County Council (offices, Penrhyn Road, Kingston), who will send an inspector and instruct you how to proceed.

YELLOW VINE LEAVES.—E., South Wales: I enclose some vine leaves that are showing signs of turning yellow. The vines from which they came have been planted about ten years, in an outside border that is entirely above the ground level, with a concrete base. The vines show plenty of fruit, and I am now thinning the bunches. It is chiefly at the top of the vines, and at one end of the house, that the leaves become yellowish. I shall be glad if you can suggest the cause and remedy.—The leaves are rather thin in texture, and suggest that the vinery has been kept too close during the dull weather, and consequently the leaves have suffered during the recent bright weather, being unable to stand the bright sunshine. The top of the house would naturally be the hottest, and so the upper leaves would suffer most in the event of insufficient ventilation. Probably, the position of the vinery in relation to other buildings or trees has something to do with the trouble. For instance, if the sun does not directly strike the house until it has risen fairly high, the sudden brilliance and heat are likely to prove very troublesome unless one is particularly alert. In the light of these remarks we think if you make a careful survey of the house and surroundings, you will soon find where the difficulty lies. We also advise you to be careful not to overcrop the vines, especially those that are weakened by the yellowing of the leaves.

CURE FOR WIREWORM.—F. H., Chesterfield: I shall be very pleased if you can assist me in what is proving a very serious difficulty. Two years ago I took charge of this garden, the greater part of which was a rough grass field. The ground needed for vegetables was trenched, the turf being buried, and plenty of manure added. I found the soil badly infested with wireworms, but all that were seen were picked out and killed. The ground was planted with Brussels sprouts, cauliflowers, and sweet peas, but all the crops were destroyed almost as soon as planted. Last winter the ground was again well dug, and given a good dressing of lime, afterwards soot was spread and forked in. Notwithstanding all this, the wireworms seem as numerous as ever. Sweet peas raised in pots, and planted out, have dwindled away, and I have found seven or eight wireworms at the roots of each plant killed. Cabbages are served the same, but culinary peas are not harmed. Last year a large bed of onions was also completely destroyed by the pest. Both my employer and myself will be very grateful for any help you can afford us in this matter.—The wireworm is the larva of the Click Beetle, a blackish-grey beetle about half an inch long. The beetle

GARDEN {FROM STOCK} FRAMES

lay their eggs on the ground, usually close to the roots of plants. The grub or larval stage lasts over three or four years, hence wireworms are so destructive. Old pasture land is often badly infested, and where this is the case some time must elapse before it is cleared of the pest. Any and every method should be adopted. One is to heavily dress the land with fresh gas lime in the autumn or early winter, forking this into the upper foot of soil. At the end of the winter the soil should be deeply dug again, and allowed to remain rough until needed for cropping. The gas lime must be fresh, and, if possible, three months should elapse from the time of using it until sowing or planting begins. The various proprietary soil insecticides advertised in our columns are useful aids. Traps made of hollowed halves of potatoes, pieces of carrot, and turnip, each with a short stick attached, should be placed all over the ground, and examined every day; the traps should be placed two or three inches below the surface of the soil; the stick will indicate their whereabouts, and be also a ready means of lifting the traps. Put the captured wireworms in a bucket, and eventually kill them with scalding water, brine, or paraffin.

FAILING TOMATOES.—E. C., Birmingham: Kindly tell me the reason of the failure of enclosed tomato plants. All other plants, such as fuchsias, gloxinias, etc., in the same house are doing well, and some plants from similar seed given to a neighbour have proved successful. — Over-watering and unsuitable soil are chiefly responsible for the failure. We advise you to obtain new soil, a fibrous loam, and some clean, healthy plants, and plant firmly; when well-rooted, tomatoes need plenty of water, but the soil must be firm and well drained. The plants you have are likely to prove far more trouble than they are worth, consequently we advise you to make a fresh start at once.

NAMES OF PLANTS.

B. S., Worcester.—1, Geum coccineum; 2, Viola gracilis; 3, Aquilegia glandulosa.

T. A. W., Axminster.—The fern is Ceterach officinalis, and the blue flower is Polygala amara.

V. S., Enfield: 1, Phlox setacea; 2, Saxifraga decipiens; 3, Berberis Darwini; 4, Cassinea fulvida.

J. E. B., Westerham.—1, Phlox setacea; 2, Morisea hypogæa; 3, Trillius europæus; 4, Juniperus Sabina.

F. P. D., Shrewsbury.—1, Daphne cneorum; 2, Ledum latifolium; 3, Ledum thymifolium; 4, Amelanchier alnifolia; 5, Cerasus padus.

ELCOMBE.—The calanthe we do not recognise; send again, earlier, another season; the shrub is Cupressus funebris. Why not send name and address?

C. A., Everton.—1, Linaria cymbalaria; 2, Camassia Cusicki; 3, Berberis stenophylla; 4, Leycesteria formosa; 5, Geum miniatum; 6, Miltonia vexillaria—a good variety.

MR. JOHN HEAL'S ACCIDENT.

With reference to Mr. Heal's accident on the 18th inst., when he was unfortunately knocked down in Putney High Street by a runaway horse and cart, we are pleased to have received reassuring reports. Unfortunately one of his ribs was fractured, but he is suffering principally from severe shock, and entire rest and quiet being at present absolutely essential, his medical man has forbidden his seeing anyone. We learn that very many enquiries have been made by Mr. Heal's numerous friends, showing how much he is esteemed and respected.

CATALOGUES RECEIVED.

J. F. WEST, TOWER HILL, BREWTWOOD.—Mr. West has a number of new dahlias to offer, including those of his own raising, and some Australian varieties of high repute. The leading varieties in all sections are listed in the catalogue before us.

OBITUARY.

LORD AVEBURY.

It is with deep regret that we learn, just as we are going to press, of the death of Lord Avebury, which occurred at his residence, Kingsgate Castle, near Ramsgate, early on Wednesday morning. Lord Avebury was an authority among men in many and diverse spheres, and as a horticulturist and entomologist was held in highest esteem throughout the horticultural world. To his many-sided character and wonderful achievements as scientist, politician, and business man the daily papers have paid just tribute, but it is for us to lament the removal, at the ripe age of 79 years, of one of the finest and best-loved patrons of horticultural science Britain has known.

MR. JOHN METHVEN, J.P.

On Saturday, the 24th inst., the death occurred with startling suddenness of Mr. John Methven, senior partner of the firm of Messrs. Thomas Methven and Sons, nurserymen and seedsmen, Edinburgh. Mr. Methven was at business till within two days of his death, and, though he had not been feeling quite up to his usual health, the suddenness of his demise was not anticipated. The deceased gentleman had had a long connection with the nursery and seed business of which he was the head, and which was founded by his father 45 years ago. He was also closely identified with the two horticultural societies—the Royal Caledonian and the Scottish Association—and with the Royal Scottish Arboricultural Society, on the boards of all of which he had served as an office-bearer. He leaves a widow, but no family.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

TUESDAY, June 3.—Royal Horticultural Society; committees meet at 12 o'clock; lecture at 3 p.m. on "Grass and the Toxicity of Soils," by Mr. Spencer Pickering, F.R.S., V.M.H.; Scientific Committee at 4 o'clock.
Scottish Horticultural Association.
National Amateur Gardeners' Association.
THURSDAY, June 5.—Linnean Society.
SATURDAY, June 7.—French Horticultural Society of London.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

Flowers in Towns.

Within a comparatively recent period much has been accomplished by those who take an active interest in municipal affairs to increase the brightness and interest of the surroundings of those who from necessity or choice spend their lives in populous centres. The means by which this desirable result has been effected have been of a varied character, but where administrative ability has been accompanied by a full appreciation of the manifold charms of Nature, the town dweller has had his or her eye delighted and mind quickened by the beautiful displays of flowers and foliage provided for the adornment of the various open spaces. Few indeed are the towns of any importance that have not several parks and gardens in which one or more attractive floral displays are annually provided for the enjoyment of the people. In the great towns and cities the public parks and gardens, as so well known to those who have travelled much, extend over so large an area, and are maintained in so high a state of cultivation, as to form an important part of municipal activities. That this should be so is highly gratifying, for there can be no question as to the value of open spaces in contributing to the health and the enjoyment of town dwellers, whatever may be their position in the social scale. The efforts that are being made to improve the amenities of town life by the judicious use of the various ornamental plants that will thrive under the conditions that obtain in crowded centres should not, as is so often the case, be confined within the limits of the public parks and gardens. Important as are open spaces as an essential part of the more pleasing aspects of town life, it cannot be too clearly recognised that there are ample opportunities for beautifying other parts of towns, both large and small, with suitable forms of plant life. We have only to walk through the streets of towns, wherein the administration of the bodies responsible for their management is of the best, to see how great are the opportunities for their improvement from an æsthetic point of view. When, on the other hand, a visit is made to towns in which but little attention is paid to matters other than those of a distinctly materialistic character, one is so struck by the bare walls that flank the streets, and the absence of flowers from the windows as to at once understand how depressing must be the appearance of the streets upon those by whom they are being constantly used. The great need of practically all the larger towns is a fuller recognition of window gardening as a means of beautifying the streets. Entered into with some spirit and conducted along proper lines, it will afford an immense amount of pleasure to the occupiers of both private houses and business premises, and, with combined effort, the whole aspect of the streets will be changed. This need was recognised some years since by the municipal authorities at Liverpool, and practical expression was given to this recognition. With a view to encourage the working classes of the city to embellish their windows with flowers, the Corporation annually distributed large numbers of window boxes well furnished with plants. among those who made application for them. As the result of this procedure many streets, if not converted into avenues of flowers, had much of the bareness so depressing to those who are "in city pent" swept away. More recently the question of encouraging the cultivation of plants in window boxes has engaged the attention of several other municipalities in the Midlands and the North, notably those of Preston and Sheffield. The authorities of these two great industrial centres have proceeded on different lines to those laid down at Liverpool, and limited their activities in this direction to arranging a series of competitions for the summer season on which we have just entered. At both centres the competitors are grouped according to the wards in which they reside, and, as a separate set of prizes is provided for each ward (which, by the way, will have its own committee), the competition will be on terms as nearly equal as it is possible to make them. Each of the two courses of procedure has its advantages, and it would be a matter of considerable practical importance to discover the course by which the best results are obtained. To the poorer classes it is, of course, an immense advantage to be relieved of the cost of providing the boxes and the soil, and plants with which to fill them, and, in admitting this, it has to be considered whether window boxes so provided have the same interest taken in them as those which are obtained by the occupiers of the houses. It is a matter of common knowledge that many things which can be had for the asking fail to obtain an appreciation proportionate to their worth, and we have in mind several towns, notably Kingston-on-Thames, where window gardening has attained to a high state of development with no further encouragement than is provided by an annual competition for prizes provided by the public bodies or private donors, or the two combined. The essential point in entering on the development of window gardening in towns is to interest the people in the plants and their cultivation. The offering

MR. WYNDHAM FITZHERBERT.

of rather liberal prizes in accordance with a well-devised scheme is one means of accomplishing this object, and another is to assist those who may be desirous of beautifying their windows with flowers by advice on the selection or making of boxes, soil preparation, and the selection of suitable plants. The best results will probably be obtained by a combination of the two courses of procedure, and the advice could be given in the form of a lecture or practical demonstration, the latter being preferable. Window gardening of the future may be greatly helped by a still further development of children's flower shows. If children are encouraged at a comparatively early age to grow a few bulbs or plants, and to enter into competition with each other, they will become so interested in plant life that they may be expected to retain more or less affection for them in after life. In the case of children, there is no great objection to providing them with plants or bulbs, and the materials for their cultivation, but they usually become keen gardeners more quickly when they have to pay a halfpenny or a penny for the plant, pot, and soil. Dwellers in towns should be encouraged to not only make the most of the opportunities they have for engaging in window gardening, but also to clothe the walls of their houses with suitable climbers; those of free growth, light in colour, and easy to keep in proper order are preferable, and the well-known Ampelopsis Veitchi may be mentioned as one of the best examples of such climbers. It is a point of some importance that not only should private houses contribute their share to beautifying streets by means of window gardens, but that business premises should take advantage of the opportunities they possess for the production of floral effects. Many are the balconies and projecting windows that are now wholly destitute of flowers which may be utilised in the arrangement of displays of great beauty. We now and again meet with a most charming floral effect in association with business premises, like an oasis in the desert, and we would suggest that in schemes for the encouragement of window gardening in towns the desirability of stimulating an interest in flowers among those occupying premises in the commercial parts of towns should not be overlooked.

Mr. Wyndham Fitzherbert is well known to our readers as a writer upon the art of gardening, and for his familiarity with those plants which grow so well in the warmer parts of our islands. Widely read and widely travelled, with a keen eye and fine memory, and the pen of a ready writer, it is small wonder that his articles are always read with the greatest attention and interest. Always a lover of plants and gardening, Mr. Wyndham Fitzherbert has added to the knowledge he possesses of tender plants and shrubs by five journeys to the Cape, where he studied the Cape flora. He has been round all the principal islands of the West Indies, has spent some time in Algeria, and on several occasions has toured the Mediterranean shores, where sub-tropical plants are such a wonderful and pleasing feature. Mr. Fitzherbert writes, not only as a keen observer, but from practical knowledge as well, for at Kingswear, in South Devon, he has a garden of which he is very fond. As a photographer of garden subjects he is also successful, and on many occasions reproductions from his own photographs have accompanied his articles in our pages.

May Sunshine. — The "merrie month of May" just passed did not create a record for sunshine, but it was above the average in this respect. At Kew 217 hours of sunshine were registered during the month, and the mean maximum temperature was 64 degrees, and the mean minimum 46½ degrees, against an average of 61 and 44 degrees respectively. Rain fell on twelve days within the London area, and the total of 1.7 inches was considerably less than the average. In the same district the maximum shade temperature exceeded 80 degrees on May 25, 26, 27, 28, and 29, the highest being 84.4 degrees on May 26. On no other occasion since the records began in 1858 has May shown five consecutive days with a maximum of over 80 degrees, but in 1864 and 1867 there were three consecutive days with similarly high temperature. May 19, 1868, holds the record in this direction with a maximum shade temperature of 87.6 degrees.

The Lupin Bed at Hampton Court.—One of the great present attractions in the gardens at Hampton Court is a large bed filled with the pink Lupinus polyphyllus Moerheimi. Here, as elsewhere, it is a difficult matter to fully bridge over the time between the fading of bulbous and other spring flowers, and the arrival of gay summer blossom, and the lupin bed is a very successful attempt to maintain a continuity of flowers in the beds, and one upon which Mr. W. J. Marlow, the superintendent, is to be congratulated.

Fruit Prospects in the Blairgowrie District.—The small fruits industry in the Blairgowrie and Coupar Angus district has a bright prospect in view, should present weather conditions prevail. The season is from fourteen to twenty-one days late, and this means higher prices when the crop in the south is exhausted, and also a better crop because the danger from late frosts is over. Strawberries are promising remarkably well, but, in comparison with past seasons, will be fourteen days later. Raspberries, too, except where the stem borer is prevalent, are promising, while gooseberries and currants are already well laden, and, should late frosts keep away, will give a good return. In all exposed situations the plum crop is almost a failure, as a consequence of hail showers, with rain and boisterous cold winds. On wall trees in some favoured gardens, there is an ample crop. Pears are also poor, and only from wall trees can anything like a return be expected. Apples are yet uncertain, but, should the present fine weather prevail for another week or two, there should be a record crop, as there is a very fine display of healthy flowers on almost every tree. Altogether the season's outlook is hopeful to the fruit-grower and the gardener.

National Hardy Plant Society's Outing. — Members and friends of the above society to the number of thirty-six spent a most delightful afternoon on Saturday, May 31, when, by the kindness of Adeline Duchess of Bedford, they visited the gardens at Woodside, Chenies, where an extensive collection of hardy plants is exceedingly well grown. Travelling in a special saloon from Marylebone, the party was met at Chorley Wood Station by conveyances, and driven to the gardens, where her Grace extended a personal and cordial welcome, and accompanied the party on their tour of inspection, afterwards honouring them by her presence at tea. Before leaving the grounds the Chairman, Mr. F. Bonnell, in a few appropriate words, gave expression to the society's gratitude to her Grace for the hearty welcome and generous hospitality received at her hands. The gardens at Woodside have been fully described and illustrated in THE GARDENERS' MAGAZINE, and it suffices now to say that their appearance on May 31 bore ample evidence of their owner's taste and enthusiasm in all classes of hardy plants, and reflected great credit upon Mr. J. Dickson, the head gardener.

Colley Hill, Reigate, one of the beauty spots of beautiful Surrey, was dedicated to the public in perpetuity on Saturday, May 31. Colley Hill overlooks one of the fairest valleys in Southern England, and the old Pilgrims' Way from Winchester to Canterbury crossed the top of the hill. Lord Curzon, in his dedicatory speech, referred to the great work accomplished by the National Trust for Places of Historic Interest, to whose efforts the purchase of Colley Hill for the public was due. Of the £5,000 needed to purchase about sixty acres of land £500 yet remains to be subscribed, but this amount is already guaranteed. There was a large and influential gathering at the dedicatory service, and a reproduction of an ancient pilgrimage, carried out by Reigate residents dressed in the costumes of Chaucer's time, was one of the most charming parts of the proceedings. England in general, and London in particular, should be grateful that Colley Hill is now public property.

Royal Counties Show at Windsor, June 10, 1913. The Horticultural Section of this show will be probably a great attraction. Although a larger area than usual has been provided it will be too small to provide all the space applied for by leading exhibitors, but though there must be some disappointments in this respect, a very fine exhibition is assured. The section will be in charge of Mr. T. Fuidge, the veteran secretary of the Windsor Society.

Honour for Mr. R. A. Rolfe, A.L.S.—We learn with pleasure that the French Académie Internationale de Géographie Botanic has awarded its Silver Medal to Mr. R. Allen Rolfe, A.L.S., Editor of "The Orchid Review," as the botanical authority at Kew upon orchids. Mr. Rolfe, who entered Kew as a young gardener many years ago, has been honoured this honour in recognition of his work among orchids.

London Hardy Plant Exhibition. We are asked to state that circumstances have arisen which prevent the Hardy Plant Society from holding a London show on June 13, as arranged, and in place of this special classes have been provided at Birmingham, Taunton, and Edinburgh Shows, full particulars of which may be obtained of the respective secretaries, or of the Secretary of the National Hardy Plant Society, Mr. A. J. Macself, 52, Beechfield Road, Finsbury Park, N.

Kelsey Park, Beckenham, the estate of about twenty-four acres, containing beautiful gardens, woodlands, and two lakes, was opened to the public on May 31 by Mr. John Burns, President of the Local Government Board. Through the larger lake the river Beck flows, and the outlet takes the form of a pretty cascade fall. Mr. Burns urged the local Council to purchase more acres while land was cheap, observing that a shilling spent on parks was of more value than £10 spent

twenty years hence on a hospital or sanatorium. He stated that 11 per cent. of all London was parks and open spaces, a record no other city in the world could compare with.

The first competition for this trophy will take place on July 2, and the class in which it will be the premier award is for forty-eight roses distinct. It is hoped that this trophy will be the means of inducing

to £5 6s., and this amount has been handed to the Gardeners' Orphan Fund.

Development of the Flax Industry.—Flax cultivation was formerly a considerable industry in Yorkshire, and

ODONTOGLOSSUM AIREWORTH ORCHID DENE VARIETY.

Flowers red-brown with purple margins, and a white, red-spotted lip. A.M., R.H.S., June 3. Mr. E. H. Davidson, Orchid Dene, Twyford.

Valuable Rose Trophy for Colchester.—Mrs. Egerton-Green has presented a beautiful and valuable challenge cup to the Colchester Rose and Horticultural Society, in memory of the late Mr. Claude Egerton-Green, who took a very keen interest in the society and its work.

growers outside the district to compete at Colchester.

Help for Gardeners' Orphan Fund.—The charge of 1s. which is made by Messrs. G. Bunyard and Co., Lim., to non-customers and the trade for naming specimens of fruits has this season totalled

Selby was its centre; consequently, this town has been selected by the Development Commissioners as the site of experiments concerning the industry. A grant has been sanctioned, and the preliminary arrangements are being made by the Leeds University authorities.

PLAGIANTHUS LYALLI.

This showy and interesting plant belongs to the order Malvaceæ, and is one of the few shrubby species which may be grown out of doors in the British Isles. A native of New Zealand, it is described, with a coloured plate, in Vol. I. of the "Art Album of the New Zealand Flora," an elaborate work, produced by Mr. and Mrs. E. H. Featon. In its native country, when growing under the most favourable conditions, it attains the proportions of a small tree, twenty to thirty feet high, but in the British Isles we are accustomed to seeing it as a widespreading bush six to eight feet high, or as a wall plant. Its leaves are very distinct from those of the other hardy malvaceous shrubs, for they are ovate or cordate in outline, two to four inches long, and have long acuminate apices, and long slender stalks.

The white flowers possess a purity and charm which is, perhaps, equalled only by those of the cherry, and, although there is no relationship between the two, something about their general appearance suggested cherry flowers to the early New Zealand settlers, and we are told by Mr. and Mrs. Featon that they gave the plant the name of wild cherry. Blooms appear during early summer from axillary buds, each flower being about one inch in diameter, and terminating a slender stalk two to three inches long.

In this country the bush thrives quite well in light, well-drained, loamy soil, but is only suitable for the open border in the milder localities, colder districts necessitating the shelter of a wall. It is not an easy shrub to propagate, for, although cuttings can be rooted, there are usually a good percentage of failures. Layers, however, answer better, and if they are put down during March they may be expected to root during summer. A peculiarity of the shrub is the pretty, netted arrangement of the fibres of the inner bark. On this account it is sometimes called the "lace-bark tree," the bark being requisitioned for hats and fancy articles. Although it has long been an occupant of our gardens, it is by no means as common as its beauty warrants.

W. D.

NICOTIANA AFFINIS.

This favourite old garden species is not altogether supplanted by the newer hybrids, and in the gardens of those who enjoy the twilight of summer evenings it is not likely to be, for its delicious scent is borne on the evening air as that of few plants is in the latter half of the summer, when scented flowers are not too numerous, while the pure whiteness of its blossoms shows up more after dusk than before. Its appearance in the daytime is almost as dejected as that of the night-scented stock, so well called Hesperis tristis, and is an admitted disadvantage, making it unsuitable for beds in the more prominent parts of the garden. As it is grown mainly for its scent and its power of lighting up the summer twilight, it should be planted where we most enjoy the garden at that time—near arbours or summer houses, or where we most generally sit in the evenings.

It is a very tender subject, and must be raised accordingly. As it will keep on flowering until the frost comes, it is a good plan to get it in flower as early in the summer as possible, and, as it must not be planted out till all danger of frost is considered at an end, plants must be grown on in a frame, and potted up, even into forty-eights, if they are seen to be standing still before it is safe to plant them out. The seeds are very small, and must be sown very thinly, and the seedlings pricked out into pans as soon as they can be handled, and potted up into sixties as soon as they are ready.

They are rapidly-growing plants at this stage, and should have no more artificial heat than necessary to keep them from getting chilled during a cold spell, or we shall not know what to do with them by the middle of May. They must be hardened off very gradually, and then, when they are ready to plant out at the end of May or beginning of June, they should be fine sturdy plants, with leaves nearly a foot long. They may be planted a foot to a foot and a half apart, according to the richness of the soil and the vigour of the plants. Though they are plants for the sun, they will do fairly well in partial shade if the soil is not too dry and poor from the roots of trees.

These tobacco plants are sometimes recommended for pots in greenhouses, and one or two are worth having there for the sake of their scent, which is very pronounced in the damp air in the morning and evening. It is also worth while to grow a few as pot plants in the open, as they lend themselves so well to plunging in vacant or thin places in the mixed borders in July or August.

ALGER PETTS.

FRUIT PROSPECTS IN THE NORTH.

Our Aberdeen correspondent states that appearances in the north-east of Scotland this year point to a capital crop of fruits, especially strawberries, for which the county of Aberdeen is so well known. The outcome, it is to be hoped, will make up, in some measure, for the poor results obtained from this crop last year. In the Deeside valley, where hundreds of acres are planted with strawberries, the earlier varieties are now in full bloom, and, given a fairly normal season during the formation of the berries, a grand crop should result. It has to be noted, too, this year, that the plants are showing a much sturdier appearance than they did at the corresponding date last season. Of course, the risks of frost are always with growers. There was a very good crop of gooseberries last year, but this season it will not be so good, being only fair in some districts, and very poor in others. The high winds prevailing during the middle of May wrought much havoc among the "grosers." There have been no signs as yet of American mildew, but growers are on the alert. Currants, both red and white, are promising well, and the blacks look like a fair average. The black currant mite was responsible for the destruction of thousands of bushes last year, with the result that their numbers are now much below what obtained some years ago. Reports of the freshly-imported stock being affected are rife, and growers are finding it more and more difficult to cultivate this berry. Some growers are trying their hand with the loganberry, but only with a fair measure of success.

Of apples, plums, cherries, etc., the outlook is very satisfactory, as all are showing a wealth of bloom. No doubt this points to a good crop, but the practical grower knows full well that the best "bloomers" are often the worst "fruiters," and get rid of them at the earliest opportunity.

Summed up, the fruit prospects in this quarter are decidedly above the average, but it will not do to halloo until one is out of the wood, as there are so many untoward risks to contend with in the way of weather and disease. That such misfortunes may not be the lot of growers this year is the sincere desire of all who wish these hard-working, industrious folk well.

ROSE GOSSIP FOR JUNE.

I am penning these notes on the 20th of May, and, in not a few instances, our roses, fully exposed to the weather, are more backward in growth than I can call to mind for many years at this date. They are not looking badly, on the whole, but the frequent spells of uncongenial weather have checked the growth generally so active at this time, while the young shoots of maidens have not yet put on that promising look that makes even the foliage a delight.

I think some few readers may not have noticed the great protection against unkind winds provided by the early staking of our maiden roses; but it is so manifest that I would make a point of staking long before the plants needed it as a suppose only. The recent winds, too, have increased our plague of rose aphis, even where fairly well looked after, and it only emphasises more fully the great need of prompt and persistent methods of prevention. I noted some growths that were perfectly clear of fly just previous to the set of the wind in unkind quarters were completely smothered with fly a clear day afterwards, and this is by no means the only time I have noticed both fly and mildew take a firm hold with startling suddenness at such changes.

The frequent hoeing between the cuttings of roses inserted last autumn often means all the difference between success or failure, and never more so than during the early days of June, when their little amount of sap is active, and the weather so changeable. After the first loosening of the soil between the rows tread a little of it close to the cuttings, drawing up a small portion of the remaining fine soil towards the cuttings to aid in filling up cracks and securing more uniform moisture. These remarks apply equally to any cuttings of rose stocks inserted at the same time. Should the ground be very dry, I have found a few cans of water poured along the rows, and right into the cuttings, a considerable help to them.

A little extra cultivation, and a mulch around the base of wall and pillar roses will often be advisable now. In fact, it is quite necessary, in many cases, particularly where these extra-strong growers have comparatively little root run; and this is often the case. Indeed, it is quite surprising how some of our old climbing roses can do so well with a hard, and often paved, surface so close to their base. In such cases, a little loosening, or, rather, piercing, with an iron rod or spud will allow more copious supplies of liquid manure to percolate to the roots than could possibly be the case otherwise. During the prevalence of dry winds, a free use of the syringe, even with soft water alone, will do much good as a wash, and to ease the rapid drying up of young foliage against a dry wall. But the cost of a little insecticide is so small that I would at all times use a weak solution.

Under glass we need ample, but careful, ventilation, also to bear in bind how very rapidly the plants dry up under glass, as the atmosphere outside becomes dried. Many of the dwarfer growers can now be removed to the open, but far too often climbers in pots, as well as standards and weepers, are put into the open too soon.

ROSARIAN.

SANSAW, NEAR SHREWSBURY.

Among the many thousands who annually visit the great horticultural exhibition held at Shrewsbury during the month of August, not a few travel to the county town of Shropshire over the line running thence from Crewe and Chester. If keen on gardening matters, and not wholly absorbed in the exhibition, they must have noticed an interesting garden quite near the railway, not far from Yorton. For many years I had wondered who owned this garden, with its fine trees, wide lawns, its rising ground, as well as its pools of water, and the peaceful quietness that seemed to reign over all. My curiosity led me to make inquiries of Mr. J. Eckford, when at Wem, and he promptly satisfied my inquisitiveness by driving me over the same evening.

The residence and gardens possess the very curious name of Sansaw, and are situate in the parish of Clive, near Yorton. They belong to F. Bibby, Esq., who, however, resides mostly at Hardwicke Grange, another Salopian estate. Mr. Knowles, the gardener at Sansaw, is an old pupil of Mr. Crump's, at Madresfield Court, and, consequently, he is a keen fruit grower as well as a good all-round man.

Sansaw is pleasantly situated. The garden front is shown in one of the accompanying illustrations, and the big beeches and a fine blue spruce figure prominently in the same view. Roses are abundantly planted in proximity to the entrance; indeed, roses have been freely planted throughout the gardens, in beds and borders, and trained up pillars, over arches, or along low wire fences, and they flower uncommonly well. Rhododendrons are effectively grouped near the entrance, and hereabouts some giant beeches, a splendid Sequoia gigantea, and fine deodars are strikingly attractive features that show how great has been the care bestowed upon trees. Erect Irish yews are in fine condition, and there are a number of specimens towards the margins of the lawn. Lilacs, too, are capital, and a good collection of varieties has been planted in the wide border that separates the garden proper from the meadow land beyond.

Hardy flowers abound, but in only a few instances are these planted in straight borders. Shrubberies have been cleared, or severely thinned out, leaving only a suitable background for the herbaceous plants; a widening of the borders, thorough trenching, and the provision of a winding front line, have permitted the free grouping of all the best hardy flowers in an informal manner. Herbaceous plants never seem so much at home as when they have a background of trees or shrubs, and a frontage of well-kept lawn. The one great difficulty is lest the trees and shrubs rob the plants of their needful food, but this can be overcome. At any rate, it is overcome at Sansaw, for phloxes are as near perfection as may be, and they are always a good indication of the cultural methods followed. They were splendid in August, and so were gaillardias, phlomis, rudbeckias, especially the tall double form of R. laciniata, Galtonia candicans, asters, and zinnias. Annual flowers are freely used in the large borders, as well as in the straight borders just outside the kitchen garden walls, and they are so managed that they yield their beauty just when the first great flush of summer flowers has passed.

Clematises are very fine at Sansaw, and as they do well here they have been freely planted. They are growing on fences, against walls, and up larch poles, and at the time of my visit a particularly good form of C. Jackmanni was smothering a low wire fence at the end of a border with its fine violet-purple flowers. C. Marcel Moser was good, and so, too, were Countess of Onslow, the violet-purple Coccinea hybrid, the soft lavender Queen Alexandra, and C. viticella Kermesina. Clematises are so beautiful that they deserve wider cultivation, especially in gardens where they do well.

In the lower part of the gardens, near the railway, there is a considerable area of water, with a goodly island furnished with fine old oaks, planes, chestnuts, ash, elms, etc., with a marginal planting of shrubs, and spring-flowering bulbs between. A little way from the water a new rose garden has been made, and leading varieties planted. Every type of rose is represented, and there are arches and pillars for the ramblers and strong growers, as well as beds and borders for the dwarfs and standards. To separate the rose garden from a little nursery garden, where bright-hued shrubs, etc., were being grown for future planting, a thin belt of trees had been formed, but to prevent any appearance of bareness Mr. Knowles had made free use of two quite common subjects, and had produced a really fine effect with them. These were giant sunflowers and the variegated maize. In the fairly stiff and rather moist soil these had grown amazingly, and the sunflowers, in several varieties, towered above the maize and the shrubs, and their great golden flower heads made a brilliant scene that was most effective when viewed from a little distance along the water-side.

Sansaw differs from most gardens of any note in that it possesses no rock garden. However, it does not lack alpine flowers, especially those that flower early in the year, and these are grown in rockery banks near Mr. Knowles' pretty half-timbered house, but on the opposite side to that illustrated. In this view, the entrance to the little home farm is shown, with a quite considerable hill rising in the background.

SANSAW, NEAR SHREWSBURY, THE RESIDENCE OF F. BIBBY, ESQ.

The aforesaid banks contain many kinds of primulas, with alpine auriculas, veronicas, alpine phloxes, dianthuses, aubrietias, saxifrages, alyssum, etc., but the aim is to secure a bright and varied display, rather than a collection of rarities, and the aim is realised. Above the rockwork flowering shrubs are grouped, chiefly berberis, spiræas, azaleas, rhododendrons, and hypericums. Sansaw is a charming garden, a beautiful and quiet retreat, where good things, old and new, are used to advantage, and for the pleasure of the owner; it does not make any claim to notice as the home of the latest introduction, and the most up-to-date novelty; there is no excitement, no rushing from this new species to the other latest variety, and, probably, those most interested in the garden are wise in their generation, because, after all, there are plenty of good plants that are neither new or rare, and an abundance of beautiful flowers that are neither expensive or difficult to manage. We all desire progress, and know full well that novelty is the spice of life, but surely there is as much progress in getting the very utmost out of well-known subjects, as there is in keeping alive a rarity from the other side of the world.

Glasshouses do not form a large item in the Sansaw gardens, but fruit culture is a fine feature. Seldom are such fine Brown Turkey and Brunswick fig trees to be found out of doors as on the very high walls, facing south, just beyond Mr. Knowles' house. Pears are managed in great style, and favouring walls are clothed with trained trees in various styles, but cordons are generally planted when vacancies arise. Apples, too, are well cared for, and the trees have been brought into excellent health by spraying and proper thinning, rather than an excessive use of the pruning knife. In many cases regrafting has turned unprofitable trees into profitable ones, for Mr. Knowles is an adept at grafting and budding, and takes a keen delight in creating a new tree or rejuventating an old one. In the kitchen garden, as among the pears, apples, peaches, figs, and plums, Mr. Knowles maintains a high level of cultivation, and probably, if he were not so exceedingly modest and retiring, he would secure fame as an exhibitor of fruits and vegetables, for there is no question as to his ability as a cultivator.

Mention must be made of the Lady's Garden, an elongated rectangular lawn, enclosed on one side by a hedge, and on the other side and at one end by flowering trees and shrubs, notably lilacs, and flowering plums and cherries, but open at the lower end towards the side of the mansion, where, during summer, large specimens of hydrangeas, fuchsias, and Agapanthus umbellatus add to the brightness of the surroundings. This is an ideal retreat for afternoon tea, for pleasant chat or serious talk, for the beginnings of life's romance, for the concluding days of a life well spent, for childhood's play, and, dare it be said, a fine place for the offering up of incense —Havana or Manilla—at the close of a summer's day. Such retreats as these are, alas! none too plentiful in modern gardens.

C. H. CURTIS.

HERBACEOUS BORDER AND IRISH YEWS AT SANSAW.

Exacum macranthum.—Seedlings of this very pretty blue-flowering plant must be pricked off when ready. We prefer to place three seedlings in a small pot, and when large enough transfer the whole to 48's. When about four inches in height the plants are pinched, and then allowed to grow and flower. They are grown on a shelf in the shady part of the stove, and as the flowers develop care is taken that they are not sprayed when syringing the house, or the flowers become spotted and spoilt.—H. PRIME, Hatfield House Gardens.

THE STEPHANOTIS.

This plant is one of the very best for training on wires under the roof-glass of an intermediate house or stove structure. In many first-class gardens it is grown to perfection, but in some fairly good places are grown, but they are not well flowered —over-shading is, often enough, the direct cause of a lack of flowers. When grown in some structures a light shading will not materially affect the maturing of the wood, but in others where shading is put on rather thickly, chiefly for the benefit of pot and other plants on stages, the stephanotis under the roof suffers very considerably.

I know of one very large specimen growing in a palm house where many kinds of stove plants in pots are also cultivated. The stephanotis makes long-jointed shoots every year, but flowers are not freely borne on them. The house is very heavily shaded every summer, a permanent shading being put on.

I have had shoots so short-jointed that the main leaves overlapped considerably, and the trusses of flowers were also very close together, so that if stems were cut off they would form wreaths of natural shape without the special placing of any blossoms. In this case the plant was rarely shaded.

Plants trained under the short roof of a three-quarter span house—the short roof facing east or north—do very well, indeed, without any shading. Inexperienced cultivators often train the shoots near to the glass, and, furthermore, allow them to curl around the wires; then there is much trouble to face when it is necessary to take down the shoots for pruning and cleaning purposes. It is a lovely climber and deserves to be grown more extensively.

G. B.

IMPRESSIONS OF THE CHELSEA SHOW.

It was a glorious morning when a friend and myself set out for Chelsea. To use the Yankee expression, we had made arrangements some time previously "to do the show" well; so after a tramp of a few miles we arrived at the station, and there met a whole host of our gardening friends going by the same train. As the show at Chelsea was to be a big affair, so gardeners who were anxious to improve their knowledge flocked thither.

Arriving at the show in good time we found it not too overcrowded, so we were able to inspect the exhibits carefully. "What do you want to see most particularly?" I said to my friend. "Oh, all of it!" was his reply. Then we commenced on one side, and went through the big tent.

The first glance gave one the impression that the show was better organised than the International held at the same place last year, but those responsible for allotting the spaces evidently did not expect such a crush, or more room would have been allowed between the tables, especially where the cut flowers and smaller hardy stuff were staged. My impression was that, had these been arranged at the sides of the tent, leaving a broad gangway all round, visitors would have been able to inspect them more minutely. The elevated exhibits of orchids would have looked much better had they occupied one end of the tent, where grouping could have been more effective. I hope my friends will pardon these suggestions, as I am still a "learner" in the art and craft of gardening. My friend and I rambled round for the purpose of learning all we possibly could, for one is never too old to pick up a wrinkle or two. It would be difficult to describe all we saw, but the impressions left on one's mind by some of the exhibits were not the most favourable.

Among the cut flowers I did not find the exhibits arranged with that taste and effect expected; the idea that seemed most prevalent was the display of the largest number of flowers possible in a vase or space, regardless of their colours. There was a want of good taste. Tulips, sweet peas, anemones, and the like were not well staged. For instance, I missed a display like that put up by Mr. Norman Davis at the Bicentenary Sweet Pea Celebration at the Crystal Palace some years ago. I well understand that it was early in the season for sweet peas; but in these days of enterprise one expects something more than finely-grown flowers and beautiful varieties.

Tulips, too, though there were some splendid blooms, were not well arranged, in my estimation. A table of anemones attracted my attention very much, and it was a pity such fine blooms were not better displayed. Then, on a table of alpines, an exhibitor had tried to crowd the greatest number of plants possible into the space allotted him, and he accomplished the feat in a most marvellous manner. When one visits a Royal Horticultural Society's show one expects to see the art displayed "that doth mend Nature," not distort it.

It was pleasing to see the double begonias so arranged that every plant was made to act its own part. The orchids, with the exception of those staged by Mr. Alexander, were, I think, much too overcrowded. Flowering plants from seeds were in great force. I took particular notice of one group of cinerarias; had two-thirds of the plants been left at home, and the rest arranged more tastefully and lightly in the same space, the effect would have been far more pleasing, and visitors would have had a far better idea of what the plants were like. Ferns were well and effectively shown. No doubt someone will say, "But ferns are easily put up." So are other plants if a little taste and judgment are exercised; and it must be remembered that we who are not so proficient in the decorative art attend these exhibitions for the purpose of improving our knowledge.

One thing that impressed me very much was the soft green of the grass grown on a felt-like material, and I thought this would make a good groundwork for many of the cut flowers.

It was too early in the season to expect a large display of either fruits or vegetables, but of these there were some creditable exhibits. One would have thought that, after the wet and sunless season last year, hardy shrubs would not have bloomed so profusely, but of these there was a great display.

Space forbids further remarks on the many and varied things seen; but, on the whole, the exhibition was a great improvement on the last Temple Show; and my impression is that, if the whole of the large tent, except the side stages, were devoted to groups on the ground, these could be viewed with far more ease, and the general effect would be better.

I now pass to the rock gardens. Here there was an improvement. There were few stones set up on their ends as though they had dropped from the sky. The arrangements were a little more natural than usual, but the thing was much overdone. It is a pity to force plants into bloom specially for this purpose, and it is misleading to those who are not well versed in this branch of horticulture; but, on the whole, there appeared to be some improvement even in this direction.

Taking the exhibition as a whole, the R.H.S. Council have every reason to congratulate themselves on their success. The weather was all that could be desired, the attendance good, and so I hope there will be a handsome balance on the right side.

H. C. PRINSEP.

VIEW IN THE PLEASURE GROUNDS AT SANSAW.

BEAUTY SPOTS IN INDUSTRIAL TOWNS.

It is somewhat surprising that, in spite of our wonderful progress in Nature-study, the average boy or girl, or even adult, who beguiles a few minutes in a greenhouse, finds it difficult to name correctly a dozen plants. Everybody agrees that flowers are among the sweetest things on earth; everybody loves to feast eyes upon them; and most people appreciate their value in brightening and beautifying our home-life.

Unfortunately, we cannot all afford greenhouses, especially with rare varieties and sumptuous blooms. It is, therefore, necessary to encourage local authorities to spend wisely and well in providing flowers for the people. Our schools are forging ahead with the diffusion of plant knowledge; and greenhouses, large and small, might be used more extensively in class teaching. Half an hour in a well-ventilated greenhouse would impart more permanent instruction to a boy or girl than pages of book work or days in the class-room. Adults might be encouraged to prepare their own "houses" at home. The happiest of leisure hours could be spent here, and there would be a constant supply of blooms for the house and table.

People of all grades now take a livelier interest in the culture of flowers. Small greenhouses built with loving hands and hearts, out of pockets with modest purses, now garnish backyards, courtyards, stable-yards, and mill-yards, where nought could once be seen more cheery or elevating than bricks and mortar, or heaps of stone and rubbish. There has been, during the past few years, a most appreciable change in town and country. Garden "cities" and suburbs, cottage-garden competitions, exhibitions of plants, and "beautiful town" societies have wonderfully revived our inborn love of flowers. And the multitude, rather than the privileged few, spend their happiest hours in the garden and the greenhouse.

This remarkable development has touched the municipal life of the nation. The time-honoured call, "Vox populi!" is heard on every hand asking for "flowers, beautiful flowers." But a short while ago the citizens of our large municipal centres knew little, and saw less, of conservatories owned and paid for by themselves. These, if existing at all, were located in a quiet retreat of the public park, where the general public were forbidden to enter. And this ancient notion of "privacy" in conservatories belonging to the public is still preserved in some towns.

Quite recently a company of visitors, including amateur gardeners and naturalists, entered the public park of an important industrial centre, and desired to examine the lovely specimens in the conservatory. Here was an obvious treat, and all hearts rejoiced at the promise of half an hour's real enjoyment. In the ornamental garden the flowers were at their best; all were aglow with brilliant rainbow tints; and the air was fragrant with sweet odour. As we approached the gateway leading to the conservatory, imagine our disappointment on reading this glaring notice: "Private—No admittance past this gate." And, of course, this instruction was as the laws of the Medes and Persians. There could be no entry. The people who had shared in the cost of the plants and flowers must not be allowed to see them. Thus, it unfortunately happens that all over this favoured Isle of Flowers the people have conservatories well tended, and garnished with the prettiest blooms of Flora's treasury, which bud and spread their charming petals to the admiration of hard-working gardeners; but they wither without the eye of the people having once gazed upon them.

What a pity! The eyes of thousands would have been brightened; the hearts of the multitude would have been cheered by the sight of such realms of natural beauty. If the every-day toiler who possesses neither garden nor greenhouse could, even for once in a week, spend half an hour, or a few minutes, in such an atmosphere of charm and fragrance as is to be found in the people's conservatories, a new phase would turn upon his aspirations; new ideas would dawn on his mind; the smoke and din of every-day toil would have a temporary relief, tending to the health and comfort of the man who "pays the bill."

Happily, the movement is growing to "open the people's conservatories to the people." It may not be convenient to open on every day of the week. But at all seasons of the year, where the practice of "opening" is in operation, certain days are set apart and suitable hours fixed, for admission to the town's floral productions. Where necessary, an attendant is in charge, not with any suspicion of maltreatment of plants, but with a view to giving any information which visitors may desire on blooms or plants of special interest. Much useful information among working-men is spread in this informal manner. Saturdays and Sundays are assured as "open days," as these are the only opportunities that mill-workers have of visiting the conservatories. The wonders of Nature and art, which appear to the admiring eyes of the workers on the Sunday, afford cheerful reflections on the six days following. Here is mental food of the highest order, with its suggestions of colour, form, order, sweetness, and cleanliness.

It is often assumed that in our large industrial centres, where the atmosphere on six days of the week is begrimed with dust, smoke, and fumes, the superlative beauty of plant life is impossible. And something may be said in favour of this contention. A vast amount of tree-planting, for instance, has been carried out during the last decade in towns of East Lancashire and the West Riding. And the result in many cases is commiserating. Healthy young trees have been imported by thousands from the Midlands and the South, and planted in selected thoroughfares on "arbor days." Iron fences, six to seven feet high, were erected round the slender stems, and painted a rich green. All then augured well for verdant avenues and rustling foliage. But the wintry gales swept down from the bleak moorlands; the smoke and fumes from the chimney-stacks came along; and those tender twigs, which were born in a balmier atmosphere, could not perform miracles. Growth became impossible, and all that remains is the leafless trunk, with the green iron rails.

But while tree-planting has met with doubtful success in some towns, owing to atmospheric conditions, the people's conservatories, even when surrounded by a forest of chimney-stacks, show wonderful vitality and freshness. It has, indeed, surprised many horticulturists from southern counties that the cotton and woollen centres of Lancashire and Yorkshire are able to produce such "spotless" blooms. The fact is that, under careful supervision of lights and ventilators, smoke rarely enters the conservatories; and the strongest sunlight is mellowed by the denser atmosphere. Hence, in the very core of Cotton Land, with its mills and workshops, foundries and furnaces, there are municipal conservatories of the finest order. There is ample room for more and larger conservatories to be thus devoted to the education and enlightenment of the people.

The possibilities of these glass houses are practically limitless. Their contents range from the hardiest ferns to the most delicate tropical palms. Flowers of every form and colour find here a comfortable habitat. The municipal fund can provide more costly specimens than are possible to the average amateur. In the earlier months of the year the benches are aglow with hyacinth, lily of the valley, narcissus, cyclamen, and cineraria. A stand of poinsettias, interspersed with ferns, mosses, begonias, and camellias, makes a lovely setting at the close of winter. The month of March sees the rich effulgence of brilliant azaleas, tulips, primulas, and dielytras.

The summer months teem with magnificent varieties of begonia, verbena, hippeastrum, gloxinia, and calceolaria. Begonia Gloire de Lorraine makes a charming basket of bloom, admired by all observers. Schizanthuses produce a mass of flowers in July and August, when hydrangeas and passion-flowers are at their best. The autumn months bring forth the lilies dear to the heart of every lover of flowers. The benches are then decorated with luscious specimens of geranium, petunia, fuchsia, and Hydrangea paniculata.

The chrysanthemum season arrives, and flower heads of white, yellow, pink, and chocolate tints reveal the splendid possibilities of the town conservatory. Even "dull November" is neither dark nor dull here, for the harbingers of spring are open to view—narcissus and snowdrops. When Nature outside is held in the grip of winter, there is life, and warmth, and good cheer among the floral gems of the people's greenhouse.

J. H. CRABTREE.

Thinning Vegetable Crops.—Many kinds of vegetables will need immediate attention in respect to thinning, weeding, and hoeing. Onions should not be severely thinned, bulbs of medium size being the more useful and better keepers. Draw the plants with care so as not to disturb those left to mature. Vacant spaces in the rows should be filled by dibbling in spare plants: this operation is best done during showery weather. When the thinning has been completed, and an attack of the grubs of the onion fly is feared, give the beds a good dressing of soot. Carrots, parsnips, spinach, turnips, and beetroots should receive attention as soon as growth is sufficiently advanced for the purpose of thinning.—W. MESSENGER.

BEDDING OUT IN SHADE.

Those who experience difficulty in keeping the shadowed portions of the garden more than neat during the winter months should take full advantage of summer's opportunity for creating bright masses of colour in those usually dull places. The great secret of bedding out in shade is to make such thorough use of bright hues that the limited amount of light and the absence of any sunshine no longer has a depressing effect. There is no reason why stretches of ground under tall trees should not be some of the gayest, and it is beneath the kindly shelter from heat that chairs will be set, or seats most occupied, bringing flower-lovers constantly into the presence of the floral achievements.

The golden calceolaria—in its older amber form and the taller growing lemon-yellow C. Burbidgei or C. amplexicaule—stands out pre-eminently as the bedding plant for simulating sunshine where none can enter. When it is employed in conjunction with crimson and silver foliage, blue of the lobelia, lavender-blue of the ageratum, as so often witnessed, it is bound to part with much of its power to cheer; if massed over a large surface, with Pyrethrum aureum and yellow bedding pansies, the result will far surpass that of the older style. With a wide border of white bedding pansies, too, the calceolaria has a lively appearance.

The terra-cotta brown calceolaria is another most valuable flower if its peculiar merit is not frittered away. When associated with grey, silver, lavender, or white, the rich hue seems to lose all its distinction and serves but to show up those others. To see it at its best it should be accompanied only by beets, which will flourish finely out of the sun, or some flowers of its own bronzy-crimson, as Tom Thumb coreopsis Crimson King, and some dwarf nasturtiums. It should be given an edging of some dull rose flower, such as Tom Thumb nasturtium King Ruby or rose bedding pansies. The warmth of this combination will be welcome to the eye in shadowed beds, for the tints usually seen under trees are cold ones. There are snapdragons, too, that are of immense service, all the maroons, deep reds, and pink varieties. Scarlet flowers, strangely enough, have a less cheerful look, although there are some that will thrive. For example, a perennial mass of scarlet geum, alternated with scarlet snapdragons, with corner clumps of montbretias, will be in flower in the chief months. Temporary scarlet bloomers include pelargoniums, but the soil should be made light with brick rubble and sand if naturally heavy and adhesive, or else the foliage will be produced too lavishly, at the expense of the blossom. Verbenas cannot be recommended; sweet peas bloom late in shadow but make beautiful backgrounds, and the fewer sprays they supply than in sunshine will be of perfect, unbleached colour. Tropæolums can be fairly relied on, though the vermilions need more light and warmth than do the golds and the crimsons, but the miniature type, known as Liliput, will provide a vivid carpet.

A pure white bed with a gold carpet has unique charm, and may be made with Pyrethrum aureum and groups of nicotianas and white single petunias. Of course, permanent plants of suitable nature are exceptionally numerous in white, including columbines, Chrysanthemum maximum, campanulas of the taller species, foxgloves, Jacob's Ladder, galegas, achilleas, early chrysanthemums, and Michaelmas daisies.

Special embellishments for summer use may include painted tubs of bedding plants. Those who wish to practise this method should avoid the common shade of green paint, and obtain the most vivid grass or pea green, which will not look garish in the shade. Brown paint of a ruddy hue is admissible, yet has a decidedly obtrusive effect, calling undesirable attention to the artificial introduction of receptacles. In a strictly ornate garden, by a modern villa, for example, white-enamelled tubs of beets, fuchsias, geraniums, marguerites, coloured nicotianas, and calceolarias will not be out of place, and any shadowed border can be considerably lightened by setting up a white trellis at the back. The Flame Flower, Tropæolum speciosum, should be permanently used for this trellis, but climbing nasturtiums can be added each summer.

Old tree stumps, hollowed out, and stood on end, make satisfactory ornaments under tall trees; scarlet ivy-leaved pelargoniums will do well in them, while golden ivy should be planted at their feet and trained up the wood. Pillars of white-painted gas-piping, with golden ivy alone trained up them, afford height and some beauty in the worst positions. The lower tree branches will often supply arms from which to sling hanging baskets which, if well filled with bedding plants cannot fail to please.

Then by sinking relays of pot plants we can keep up a constant flower show. Drip and draught, those great enemies of bedding subjects, can be endured for many weeks; if the pot beauties are stood out for as many more weeks in sunshine they will recover from any harm they have taken, and their new crop of buds will open perfectly after they are resunk where conditions are adverse. In addition to pelargoniums, marigolds, salvias, petunias, tall lobelias, asters, and stocks may be thus pressed into service. Begonias are unsuitable where there is drip, though when they have started to bloom they will continue to do so without direct sun heat.

A few foliage carpet beds can be recommended as soon as the striking displays of colour have been located; most of the familiar minute silver, white, green, gold, bronze, and crimson-leaved plants will keep in health from May to November in sunless spots.

A trial of some rare and delicate plants in combination should also be made in shadowed beds away from trees; the aspidistras and Primula obconicas of the greenhouse will be benefited by a summer outing; Plumbago capensis, and mimuluses or balsams, will furnish other beds. M. H.

THE GARDENER'S HOUSE AT SANSAW.

FLORISTS' AURICULAS.

Among the flowers dear to the hearts of the old florists the auricula has always held a foremost place, and, despite the fact that modern tastes have become more catholic there are still a goodly number of enthusiastic devotees to the cult of the auricula, to whom perfection of form irresistibly appeals. I have no desire to quarrel with those who claim that, so long as a plant produces a quantity of bright and pretty flowers in the garden, it matters little or nothing whether the individual flower conforms to a certain standard of form, or arrangement of its various colours. What I am really anxious about is that we shall not lose the æsthetic taste and whole-hearted enthusiasm of the old florists, and that the rising generation of gardeners shall be encouraged to acquire the taste for, and admiration of, a flower that possesses the perfect points which, combined with skilful cultivation, used at one time to constitute the sole qualifications for the appearance of auriculas on the show table or their inclusion in the collection of a connoisseur.

It is no credit to anyone simply to state that he sees beauty in every flower. Indeed, to my mind, if that is as far as one goes, he is simply on a level with the avowed lover of music who knows not the work of a master from the mutilation of a novice, or he who considers his cheap prints as good as a work that reveals the soul of an artist. It is only when we are awakened to the glory of perfection, and are quickened to strive after it, that the fullest enjoyment of a pursuit, be it horticulture or any art, is realised. Hence, my appeal to the readers of THE GARDENERS' MAGAZINE, especially the younger of them, to give more than a passing glance to the flowers of the florist.

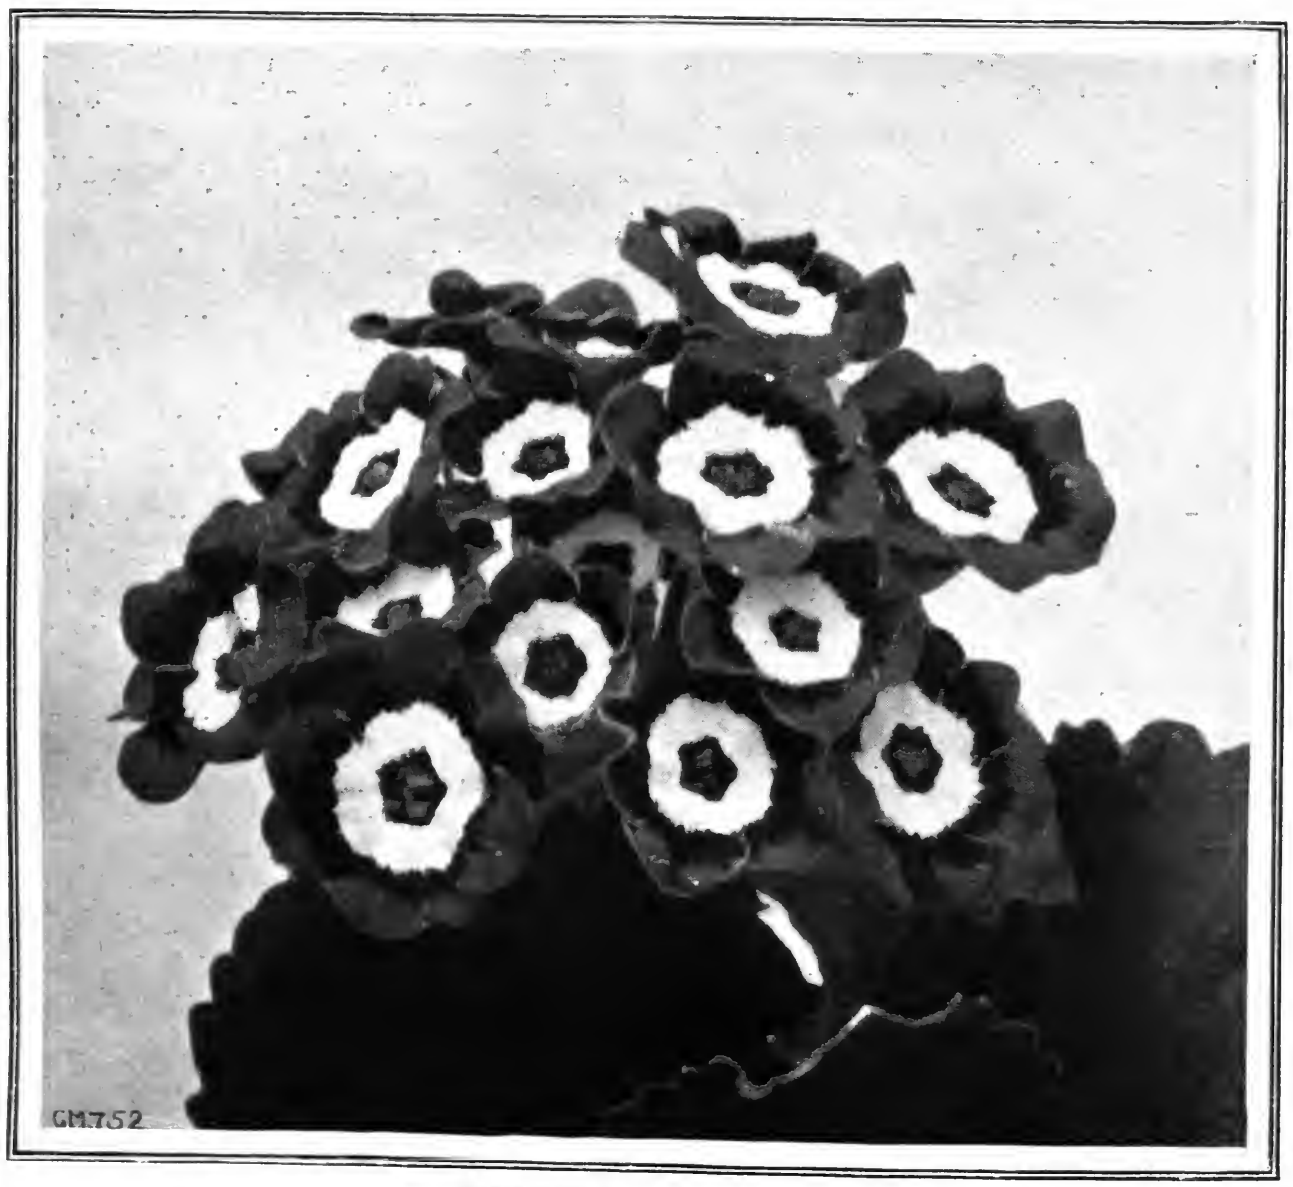
A recent visit to Mr. Jas. Douglas, Edenside, Great Bookham, gave me an opportunity to revel among his peerless collection of both stage and alpine auriculas, and I am constrained to think no true-born gardener could have been in my company without evincing some enthusiasm over the truly delightful display there seen. Whether among the green, grey, or white-edged, the selfs, or the fancies, there were varieties that represent the very finest of their sections, and whilst, of course, conversation from time to time centred on the respective merits of this variety against that, one saw now and again a flower about which all we wished to say was "It's grand!" One such variety was Harrison Weir, a rich crimson self in the show section. It is a lovely flower, showing perfection of form in every division of the pip, and in the symmetrical centre and surrounding band of rich, velvety colour. This variety has won first-class certificates and premier awards that justify its claim to being considered the best of all crimson selfs. George Lightbody is well known among auricula fanciers as the best grey edge, its points consisting of perfect golden tube, sharply defined band of dense white paste, solid black ground, and fine grey edge. Marmion, a Douglas variety, is another grey edge of outstanding merit, and, in addition to the charm of its flowers, it has fine, mealy foliage, a point that should not be lost sight of in a show auricula.

I was very pleased with Prince Charming, which Mr. Douglas himself considers a first-class green edge. It has vigour, size, good outline, and sharply contrasting colours to its credit. Shirley Hibberd, one of the late Mr. Simonite's raising, is also a very good green-edged variety. Heather Bell has an edge as white as can be wished for, and its colour, described as rich violet, appears almost black against the zone of paste and the mealy foliage. Princess May and Wild Swan are two of Mr. Douglas's varieties that may well be included among any set of white edges. Wm. Smith, a grand new green-edged variety raised here, was greatly admired at the recent Chelsea Show.

In the alpine section Mr. Douglas has several new varieties of distinctive merit, Roxburgh being one that quickly arrests attention. Its rich violet-blue throws into fine relief a clean, circular white centre, and the perfectly smooth edge of the pip is finely laced with a lighter blue. Muriel is a gold-centred flower with a fine band of mahogany crimson, and Golden Dustman is another perfectly-formed flower with an edge that could not be improved, while its golden centre and its outer band of crimson shaded with bronze, make it a truly handsome flower. Phyllis Douglas is still about as good as any of the very pretty, blue-laced, white-centred flowers, and if any raiser of seedlings sets up Phyllis as a standard, he will become very exacting when selecting the best from a batch.

Speaking of seedlings, I may say these are to be seen in great quantity at Edenside, and very fine many of them are. It is, however, Mr. Douglas's practice not to name ever so pretty a flower if it has a fault such as uneven edge, defective centre, or weak truss, whilst, of course, a pin-eye is Anathema to any auricula fancier. I have not mentioned a quarter of the varieties of which I took note, but must conclude by saying that the whole collection, although extensive, includes only varieties of unquestioned merit, and I would that many such collections existed in this country, and that high-class auriculas might become general favourites, rather than the special pets of a comparatively narrow circle of enthusiasts.

VISITOR.



AURICULA WM. SMITH.

A very fine green-edged show variety. A.M., R.H.S., May 20. Mr. James Douglas, Great Bookham.

SPIRÆA VEITCHI.

About twelve years ago seeds of this shrubby spiræa were sent to Messrs. J. Veitch and Sons by Mr. E. H. Wilson, who discovered it in Hupeh, when collecting for the Chelsea firm. Mr. Wilson was evidently very greatly impressed by its appearance on its native soil, for he described it as, perhaps, the finest of the Chinese spiræas. In the time which has elapsed since its introduction it has gone a long way towards verifying its collector's words, for it is certainly a beautiful and floriferous shrub.

Amongst the older species, it most closely resembles the Himalayan S. canescens, for it has a similarly graceful habit, with long arching shoots, clothed with small oval leaves. A difference may be observed, however, as the Chinese plant has glabrous leaves, whilst those of S. canescens are hairy. At the same time differences in the serration of the margins may be noticed. The white flowers appear from short, axillary growths towards the end of May and early June, and are produced in heads up to two and a-half inches in diameter.

A mature bush may attain a height of twelve feet, with a considerable spread, and growths six or eight feet long are sometimes formed in a single season. Some idea of the effect of a well-flowered bush may be gathered from the fact that the inflorescences appear from nearly every bud on the upper half of the previous season's growth. As is usual with shrubby spiræas, it must be given really good soil if the best results are expected. Any pruning which is done must be left until after the flowers are over, then some of the older shoots may be removed.

W. D.

AMONG THE ALPINE FLOWERS.

"A garden is a lovesome thing, God wot!
Rose plot,
Fringed pool,
Ferned grot—
The veriest school
Of peace; and yet the fool
Contends that God is not—
Not God! in gardens! when the eve is cool!
Nay, but I have a sign:
'Tis very sure God walks in mine!"

Thomas Edward Brown.

As we wander through the rock garden, either our very own or that of some friend whose garden treasures we enjoy, we find how full of meaning are the words of the poet quoted above. "The veriest school of peace" such a garden is, and we cannot but feel within it that we are elevated in both soul and body by our companionship with the flowers it cherishes and we love so well. Methinks it is a relief to turn from the clamour of the outer world, the din of faction, the striving for wealth, to seek communion with peace in its highest attributes among the flowers. The little placid pool, with its water-lilies, so calm and so lovely on its mirror-like surface; the slopes and knolls covered with the charm of verdure or the glow of bright flowers, all are inexpressibly restful and soul-reviving.

Primula Lissadell Hybrid.

Among the many primulas which came into bloom in May, and have prolonged their flowers until they keep company with the alpines of June, is that fine hybrid, Lissadell Hybrid, the offspring of the hybridisation of P. Cockburniana and C. pulverulenta. Though of the same parentage as P. Unique, it seems to bear out the claim that it is a better and more vigorous plant than Unique. Planted together, and in exactly the same conditions, the Lissadell Hybrid is finer in every way—taller, more sturdy-looking, and giving a greater quantity of bloom on a more robust stem. In a somewhat low, rather moist place, in peat and loam, with a considerable amount of sun, this soft vermilion primula is very beautiful indeed.

Saxifraga Engleri.

There are two Romeos in the field claiming the name of Saxifraga Engleri. They are both in this garden, but I have no hesitation in saying which is the better plant of the two; although, when it comes to a point of deciding which is entitled to bear the name of the great authority on the saxifrages, Professor Engler, applied to them, is entirely a different matter. The nomenclature of the silver saxifrages is a very Serbonian bog, and they are wise who do not venture far into its depths. The two named may be distinguished as S. Engleri of Messrs. Bees, and that of Mr. Reginald Farrer. Of these, I unhesitatingly prefer the former, though I disclaim any desire to say whether it is or is not the true Engleri. As a rock garden plant it is the finer, whether in or out of bloom. A plant that has been here for several years, and has been reduced in size again and again for purposes of propagation, is very fine at present, with its many beautiful, long, silvered leaves in handsome rosettes, and bearing now upwards of a score of handsome plumes of white flowers to a height, some of them, of more than a foot. It is exceedingly pretty at all seasons, and I look upon it as one of the most ornamental of all our silver saxifrages. The other S. Engleri, that of Mr. Farrer, cannot be better described than has been done by that able alpinist, when he says: "My Engleri is very handsome in the leaf, making huge blue-and-silver starry rosettes of narrow leaves. But, as the foliage is like a magnified paradoxa: so also are the dull greenish-yellow flowers that appear sparsely on the rare flower stems."

Geum Heldreichi.

Of the many plants which seed and sow themselves here, none is more acceptable in its way than Geum Heldreichi. Although a good border plant as well, it is very handsome indeed when in the rock garden, and its presence here and there is most acceptable among the lower flowers, giving both brightness and a varied aspect to the scene. My original plant was the fine variety called G. Heldreichi superba, which in colour and in size presents some justification for the magniloquent varietal name of "superba." Self-sown seedlings vary a good deal, and some of these are very beautiful with their varied forms and slightly different shades of colour, but all of orange-scarlet. One nice seedling has the Maltese cross form, which reminds one of some of the lychnises; and, although doubtless coming under the ban of the strict florist, is yet appreciated as it grows by the side of the little artificial rill that leads the water into the water-lily pool. Elsewhere, on slope or crowning low mound, a good many plants of Heldreich's avens help to lend brightness and glow to the garden.

Arenaria purpurascens.

One grows more and more surprised at the absence from even large rock gardens of certain beautiful and characteristic plants. One of the most distinct of the arenarias, or sandworts, is the dainty Arenaria purpurascens, a name which, though fairly suggestive of the colouring of the flowers, yet fails to convey any real impression of the character of the plant in other respects. Picture a little trailing carpet of shining leaves, all spangled in May and June with delightful pale lilac starry flowers, coming in midway in size between those of Arenaria balearica—that gem of gracious free-flowering sandworts—and those of the lovely white A. montana. On a spot beneath the level of the eye,

AURICULA ROXBURGH.

A Beautiful alpine auricula, violet-blue and white, raised by Mr. James Douglas, Great Bookham.

and preferably one from which one can look down upon it from a distance of three feet or so, it is a most charming little plant. Its kindliness in the way of culture is just as great as its beauty. Give it a dry, sunny position, in light soil, and it will give abundant reward.

Other Flowers.

Flowers by the myriad there are in great variety of genera and species. Shrubs, spire-like flowers of many kinds, graceful carpeters or trailers; violas in unending hues and markings, the progeny of years of the cultivation together of many of the race; aubrietias still (one of the best dark ones recalling by its name our old friend, Mr. Peter Barr); golden and white alyssums; charming armerias; spring phloxes, achilleas, artemisias, saxifrages of all sorts and sizes, lychnises—in very truth, a galaxy of grace!—all meet our eyes as we wander among them in this "school of peace," the alpine garden.

S. ARNOTT.

PLANTS IN THE DWELLING-HOUSE.

A common cause of the failure of room plants is that they are kept too wet at the roots, for they are frequently stood in ornamental vases, in which no provision is made for drainage, so that the water stands therein, and the soil becomes so saturated and sour as to cause the roots to perish. Room plants which are growing in pots and then stood in ornamental vases, jardinières, or even in saucers, should, when watered, be taken out of these receptacles and placed in a sink or some spot where the surplus water can readily drain away.

The best way to water room plants is to immerse the pot in a pail, allowing the water to be an inch or so above the rim. When the air bubbles cease from rising the soil will be saturated, and then the pot should be stood to drain before restoring it to its position. After that it may be allowed to stand till water is again needed, when the same process must be gone through. Care must be taken to ascertain whether the water is really required before this is done. Other common causes of the ill-health of room plants are unsuitable soil, ineffective drainage, and pots too large for the plant. When a subject falls into ill-health it is often put into a larger pot, whereas it probably needs one two or three sizes smaller. The spring is just the time to overhaul such room plants as aspidistras, palms, and ferns, and if they need larger pots to shift them into the size required. If, however, as often happens, the roots are in a bad state, and the soil sour, the only chance of recovery is to shake the roots almost, if not quite, clear of the old soil, repot in some good sweet compost, taking care that the pots are quite clean, effectually drained, and not too large. The after watering is also a very important matter, as, of course, until the roots take possession of the new soil, less water will be needed than when the ball of earth is well furnished with healthy roots.

S. W.

Anopterus glandulosa. — The Tasmanian Laurel, as this is popularly termed, is a very pretty evergreen shrub for the greenhouse or conservatory. It forms a freely-branched bush that will flower profusely when from four to six feet in height. The leaves are large, oblong, ovate in shape, and of a rich glossy green tint. The flowers, borne in simple erect terminal racemes, are somewhat saucer-shaped, and in colour white, or nearly so. It blooms during the spring months.—K.

THE ONION CROP.

It has been said that few kitchen garden crops are more liable to disease than onions. In the best-managed fields and gardens, in dry as well as in wet seasons, whole crops of onions are liable to devastation by insect or fungoid attack. The onion fly, for example, is a constant and vicious enemy of the crop. Successive generations of this insect have often ruined small crops of onions in allotments and cottage gardens, and in other places. At first, the plants which are attacked by the fly will turn a yellowish colour, and the first, or longest leaves will subsequently become white. These will become easily detached from the stem, and in time the other leaves will become yellow and decay. The fly causes the bulb to be small and badly shaped, and it will be found to be infested with dirty white maggots, which reduce it to a rotten and useless state. Young plants will be nearly eaten through just above the swelling bulb by the maggots of the fly.

Onion Grub.

As soon as there is any indication of a yellowish or whitish hue amongst the leaves of the plants search should at once be made for the maggot just below the surface of the ground, and, if necessary, the bulbs should be cut open and examined. The flies usually lay their eggs in April or May; about six to eight eggs are laid on the onion plant, upon the neck of the bulb, and sometimes on the lower part of the leaves, generally just above the ground. In about five or seven days maggots are hatched, which burrow down into the gradually forming bulb. Later on, when the bulbs are larger, the number of maggots which feed upon them are increased, and the earth around the plants becomes infested. The insect continues in the larval stage for from thirteen to fifteen days, then the full-fed maggot becomes a pupa inside the brown case, and the fly appears in from ten to twenty days in the summer brood. The first generation of this insect may be seen as early as April 25, and the flies have been noticed through the autumn, and as late as November.

Miss Ormerod, in her investigations into this subject, advised that after the seed is covered the soil should be well trodden and raked over. The tramplings of the feet makes it quite hard, and is considered to do good by preventing the progress of the maggot. Certainly, as far as this advice goes, there is one good result gained, namely, the seedling plants are able to secure a firm roothold at the commencement. On light soil especially, it is always advisable to consolidate the seed bed after sowing onions.

The application of a liberal quantity of soot is beneficial, as far as the eradication of many insect pests is concerned, while in field culture the application of a manurial dressing, such as eight bushels of salt on the ground in the early autumn, before ploughing, and sixty bushels of soot per acre in the spring, when the seed is drilled, or later, as a top-dressing after the plants have been once hoed, would certainly be a useful precaution against insect attacks, apart from the beneficial effects of the manure.

The practice of spraying with paraffin emulsion is also to be recommended. This emulsion may be made by thoroughly mixing together three pints of paraffin and half a pound of soft soap, with one gallon of boiling water. When thoroughly emulsified this should be diluted with about seven or eight gallons of water, when the onion leaves are young and tender, otherwise six gallons of water will suffice, the added water being necessary in order to prevent the emulsion burning the onion leaves. Spraying should be performed early in the season, when the onion plants are quite small, and it is advisable to repeat the process two or three times. Some growers prevent egg laying of the onion fly by earthing up the plants well over the neck. In any case, it is advisable to drop the crop for at least one season on soil where onions have been infested. If this cannot be done, extra deep cultivation and gas lime will be necessary.

Onion Mildew.

As regards the onion mildew, this is too common to need much description. Just at the present time, when exhibition and other bulbs are making generous and free growth, the risk of mildew breaking out is a source of worry to many cultivators. No matter how strong the plant may be, or how rich the soil, this disease makes its appearance unexpectedly on all kinds of soil, and at different stages in the plant's growth. At the onset, small yellowish patches appear scattered over the leaves, and these gradually increase in size, and so give the entire leaf a sickly yellowish appearance. Finally, the whole leaf becomes thickly covered with a grey powder.

One remarkable effect of the mildew is that in its early stages of development the growth of the plant, especially the neck, is rapidly increased. Wherever this abnormal growth appears one may be sure that the disease has gained a hold upon the plant. As regards remedies for the onion mildew, the one most to be recommended is spraying with potassium sulphide, the latter being used at the rate of five ounces to twelve gallons of water. This spray should be used before the plants become badly attacked with the disease. Potassium sulphide, or as it is commonly known, liver of sulphur, has been proved by many growers to be an excellent means of checking onion mildew. It is certainly worth a trial by every grower who is anxious to preserve his crop.

The sulphide must not under any circumstances be exposed to the atmosphere, for it will rapidly decompose or oxydise. Badly infested plants must be at once collected and burned, and a common practice is to apply frequent dustings of powdered quicklime and flowers of sulphur in the proportion of one part of the former to two parts of the latter. These dressings, however, never entirely check the spread of the mildew.

Of course, it is of the greatest importance that every trace of diseased plants must be removed, collected, and burned. It is not sufficient to throw them on to the manure heap, or allow them to rot on the ground, for the disease is almost bound to make its reappearance at another time, for a second form of fungus fruit is produced in the decaying tissues of the leaves. Even if buried for several years in the ground this fungus fruit, if brought to the surface of the soil at any subsequent period, will again germinate, and any onion crop that is then being cultivated in that spot will at once fall a prey to its attacks.

It is certainly doubtful whether any better remedy or means for preventing onion mildew can be found than the spray fluid which we have mentioned above. We have it on the authority of one of the most successful exhibition onion growers in the country that one spraying with potassium sulphide is sufficient to at once destroy the fungus.

WORK FOR THE WEEK.

THE ORCHID HOUSES.

GENERAL REMARKS.—The warmer and more seasonable weather has been advantageous to most orchids, although it has caused the rapid fading of most flowers that have been expanded any length of time. With the more favourable conditions, we are enabled to treat the plants in the warmer houses more liberally. Extra damping of the floors and spraying the plants overhead is always desirable when it may be accomplished with any degree of safety. This work will, to some extent, also check the increase of insect pests, but it is desirable to spray the plants in the warmer divisions with some safe insecticide at least once a fortnight, as prevention is at all times better than cure, and if thrips or any other pests of this nature once become established, it not only takes a very long time to get rid of them but also disfigures the plants affected. It is advisable also to close the houses reasonably early in the afternoon, so that full advantage may be obtained from the sun heat. The advantage of a light permanent shading on the cattleya houses and others of the warm section will be appreciated. The less fire heat used the better, and the heating apparatus should only be brought into use to counteract the coolness of the evenings; with a little heat in the pipes we are able to ventilate the houses during the night. This must be done with discretion, and be governed by the prevailing outside conditions. We prefer using the lower ventilators at the leeward side of the houses.

IN THE COOL DIVISIONS a greater amount of shading will be required. It is a mistake to afford odontoglossums too much light during the spring and early summer months, as this has a tendency to give the foliage a bronzy appearance, but it will generally be found that the leaves which turn this colour early in the year generally ripen off quickly, and we find ourselves with plants having an unusual and undesirable number of leafless pseudo-bulbs towards the autumn. Not nearly so many leaves are affected where stronger light is given only during the fall of the year. In the cool divisions also more moisture will be required to keep the atmosphere as cool as possible. It is a good plan to have the blinds let down early when there is a prospect of a warm day; damping also should be done early, and the ventilators freely opened. Damping should also be done again in the middle of the day. The plants may be sprayed overhead in the morning and again in the afternoon when the outside conditions are favourable to rapid condensation. During cool nights a little artificial heat may be needed, but as little as possible should be used.—H. J. CHAPMAN, Oakwood Gardens.

STOVE PLANTS.

REMOVAL TO COOL HOUSES.—With the cool houses and frames relieved of many of their occupants for the summer months, many stove plants may be removed to rather cooler quarters, giving much-needed room to the remainder, and providing a good opportunity for cleaning and rearranging. Such flowering plants as gloxinias, streptocarpus, and saintpaulias may be kept over a much longer season if removed to a cool, shaded house, where ventilation may be gradually increased as the plants become hardened. Remove all flower spikes as the blossoms lose their beauty. The earlier caladiums may also be given cooler treatment, at the same time gradually inuring them to full sunshine.

GLOXINIAS raised from seeds in spring should be ready for shifting into 4½ or 5in. pots, and, with careful treatment, they will be of much value for autumn flowering. Continue to propagate poinsettias and gardenias if a further increase of stock is required. Leaves of saintpaulia inserted now will provide nice plants for flowering from Christmas onward.

ACALYPHA HISPIDA.—Plants raised as recommended for autumn and winter use should receive their final shift. When established, remove the points at a height of twelve inches or so, retaining the three strongest resulting growths. Remove all "tassels" as they appear, and keep well syringed and under genial atmospheric conditions. Older plants grown for summer decorations will be fast produeing their racemes of flowers, and should be removed to a somewhat cooler house, where syringing and heavy damping may be dispensed with.

EUPHORBIA FULGENS (JACQUINÆFLORA).—The earliest rooted plants may be removed to a rather cooler structure, a house or pit that has been used for forcing strawberries usually providing the required conditions. Keep fairly close at first, shading the plants, but admitting light to the house. In a short time the final potting will be necessary. Pots seven inches in diameter will be preferable; pot firmly. Syringe once or twice daily in bright weather. Open the roof ventilators a little in the evening, and increase the ventilation early in the morning. Pot up younger plants as they become ready, and insert the last lot of cuttings by the middle of the month.

AMARYLLIS.—Seedlings raised last year should now be ready for shifting into 6in. pots, in which they are to bloom. Pot firmly in a compost similar to that previously recommended, and grow on in an intermediate house. Those which have flowered should be plunged to the rim of the pot within a brick frame, keeping the lights on only as a protection against rain and at night. They will not require much water, but should by no means be dried off; syringe late in the afternoon, feeding occasionally with the object of obtaining good plump flowering bulbs for next year.—H. PRIME, Hatfield House Gardens.

FRUITS UNDER GLASS.

GUAVAS (PSIDIUM POMIFERUM).—An occasional dish of this fruit makes an agreeable change to the general collection of choice fruits. The shrub can be grown with a fair amount of success, and very little trouble, on the back wall of a vinery. I prefer growing them as cordons planted at about 18 inches apart, and supported by strings. Cuttings may be inserted now and placed in a brisk heat. A fibrous sandy loam with plenty of dry cow manure and a small quantity of old mortar rubble makes an excellent compost in which to grow the plants.

COOL ORCHARD HOUSE.—The shoots of orchard-house trees, having had their points removed at the fifth or sixth leaf, are strengthening rapidly, and sending forth fresh growth which, in turn, must be pinched back to one, two, or three leaves, according to the strength of individual trees. Proceed to thin the fruits of apples and pears as soon as they show signs of swelling. Plums need to be thinned very cautiously, and it is best to defer the thinning of cherries until after stoning is completed. A light surface mulching at this stage will be very beneficial, and save much watering. Damp the paths and between the pots several times during the day. Thoroughly syringe the trees with soft water on bright afternoons, using a little quassia in the water occasionally as a safeguard from aphis. There is no need to completely close the ventilators after this date unless the structure is exposed to strong winds.

EGG PLANTS.—Young plants of Solanum melongena growing in three-inch pots are now ready for their final shift into six or seven-inch pots. Use a light, rich compost, and place the plants in a sunny position. Syringe overhead twice daily, and maintain a temperature of from 65 to 75 degrees. As soon as the fruits have formed, water the plants occasionally with weak liquid farmyard manure. When the fruits are fully coloured gather and send them to the kitchen.

EARLY FRUIT TREES.—Trees in pots which have been cleared of ripe fruit should be placed outside and made secure from strong winds. Assist them to develop plump buds in readiness for another season by taking pains to keep the foliage in a healthy condition. If the trees are in no way gross they may be given stimulants in a weak form about once a week.—F. JORDAN, Warter Priory Gardens.

THE FLOWER GARDEN.

SPRING BEDDING PLANTS.—As the majority of plants used for spring bedding are raised annually from seed, the operation of sowing is an important matter, and it is now essential that it should receive attention. The present will be found a very suitable time for sowing wallflowers, myosotis, pansies, violas, aubrietia, double daisies, etc., which are always in demand for spring displays. Some are advocates of sowing the seed of these about the middle of May, which probably is the right thing to do in cold districts, but, otherwise, if delayed until now, the plants are not so liable to become overgrown, and in the case of wallflowers, leggy, and unable to stand rough, wintry weather. If it is decided upon to sow the seed in the open ground, the soil should be worked into a fine condition to receive it; this done, draw out shallow drills twelve inches apart, and sow the seeds thinly, afterwards covering lightly and keeping the soil moist until germination has taken place. When any difficulty is experienced in raising seedlings in this manner, sowing the seed in frames recently vacated by bedding plants should be resorted to; here they will be more under notice, and can readily be given conditions suitable for germination. Sweet williams and Canterbury bells cannot be classed as spring-flowering plants, but they can be treated advantageously in a similar manner when raising them.

MYOSOTIS DISSITIFLORA, a most desirable early flowering kind, ofttimes proves very uncertain in germinating, and this may be because the seed is a season old; it germinates more freely when sown directly after it has been gathered.

SPRING-FLOWERING SHRUBS.—Many of these have now passed out of flower, and as with but few exceptions they flower on the current season's wood, every encouragement should be given them to produce growth sufficiently matured for flowering another season. It is most marked how some shrubs flower very profusely one season, and sparingly the following; sometimes this is due to climatic conditions, but more often to the constitution of the shrub becoming overtaxed. In this latter case a top-dressing of some rich material and applications of liquid manure will do much to counteract this condition. Rhododendrons and azaleas are frequently affected in this way, and can be greatly assisted by having their flowers removed directly they are over; this entails a great deal of time, and can only be practised in the ordinary way on choice varieties. Many shrubs are liable to become overcrowded, and produce as a result weak and unripened growths; here the old wood must be thinned out directly they have passed out of flower. Such treatment especially recommends itself when dealing with Ceanothus dentatus, deutzias, kerrias, weigelias, shrubby spiræas, etc. Then, again, we have flowering shrubs which, if allowed to grow at will, soon become unsightly, and eventually get broken about and die. Some of these are much improved by

annually shortening back their leading shoots when they have passed out of flower. This lengthens their existence, and adds to their appearance. Brooms and double furze are much benefited by this procedure.—T. B. FIELD, Wych Cross Place Gardens.

THE KITCHEN GARDEN.

CAULIFLOWERS. — Plants that were raised in heat and grown under hand-lights or cold frames will, in the warmer districts, begin now to supply usable heads; the plants should be examined from time to time, and the tips of the leaves bent down, so as to keep the light from the heads. Those which have come to maturity and are not required for immediate use should be cut early in the morning and put in a cool place. The plants raised from seed sown in the open should be set out on a suitable quarter, selecting, if possible, a dull, showery day for the operation. If they are put out during dry weather each plant must be well watered in. The early, close-growing varieties may be planted 15 inches apart, those of the Magnum Bonum type 18 inches apart, and the stronger growing varieties two feet apart each way. Another sowing may be made to provide cauliflowers during October and November.

PEAS.—Further sowings should be made to continue the succession according to demand. Sow in well-prepared trenches, and apply a mulch in good time to soils that dry out quickly. Put sticks to all rows when the plants are 3 to 4 inches high, and if sparrows are troublesome stretch black thread on either side of the row, five or six inches from the ground; this will check their depredations. Gladstone (selected type), Autocrat, Ne Plus Ultra, and Late Queen are of first-rate quality, and suitable for late sowings. The last sowings of the late varieties should be made not later than the middle of June. By sowing one of the early varieties on a sheltered border towards the end of the month the supply may be maintained till mid-October, and, given favourable weather, well into November.

CABBAGE.—The plants for the autumn and winter supplies should have a well-manured plot allotted to them, and, in order to have good supplies from October till early in the New Year, seed should be sown during the early part of June. The seed-beds, when dug or levelled down, should have a dressing of soot, which should be well raked in, and seeds sown broadcast. If the crop is intended to follow potatoes, it will be as well to make the sowing rather later in the month, for if the plants are left too long in the seed-beds they become starved. If the birds are troublesome netting should be placed over the beds till germination has taken place.

MINT AND TARRAGON.—Increase the stock by pulling up young pieces having roots and dibbling them in at a distance of eight inches apart on well-prepared beds. In a few weeks' time a good supply may be obtained, while the roots will be found excellent for forcing another year. Sweet basil, pot marjoram, and other tender herbs should be transplanted when the plants are large enough to handle with safety. A space of one foot between the rows and nine inches from plant to plant in the row will meet the requirements of the smaller growing herbs. — W. MESSENGER, Woolverstone Park Gardens.

Raspberries. — Reduce the young growths springing up from the base of the old stools to the required number for taking the place of those now fruiting, and for stock if necessary. The young growths, if carefully pulled up and planted at once in a somewhat shaded position, watered, and kept clean, will grow into very useful canes by the end of the season. I have repeatedly increased our stock in this way with good results. Raspberries growing on shallow land, and producing good crops, will benefit greatly by a little feeding and mulching of the roots. Keep the land free from weeds and net the fruit early.—H. MARKHAM.

DAHLIAS FOR CUT FLOWERS.

Although some professional gardeners have discarded dahlias altogether, or nearly so, amateurs have continued to cultivate them. There are abundant signs of a general revival of dahlia cultivation, and as many nurserymen possess splendid collections of these plants, it is obvious that there has always been a demand for them.

Single Dahlias.

Cut flowers for vases, especially the tall trumpet vases, are always wanted, and, in the autumn, suitable blossoms are none too plentiful. Single-flowered and other dahlias can be cut with long stems and many branches, all bearing flowers, and only a few are required to furnish the largest vase.

Twenty years ago there were not as many varieties of singles as at the present time, but there were sufficient to induce a number of good gardeners to cultivate them extensively solely, or mainly, for the supply of cut flowers in the months of September, October, and November. The plants were duly protected from frosts during the two last-named months, as I will briefly show.

In a nobleman's garden in the north it was my duty to attend to a fine batch of singles under a very able head gardener. The plants were exceedingly well grown and cared for, and the results fully justified the trouble taken. Splendid plants are easily raised from seeds sown at the end of February. The young stock should be grown on freely, but not coddled in any way, until they are ready to plant out in the second week in June.

There are various positions in which they may be grown, but I will confine my notes to the treatment of the plants grown for the production of cut blooms.

If such were planted singly, or in very small groups, in different parts of the garden, much difficulty and trouble would be encountered in the days of frost, when some covering is absolutely essential. One good batch of plants, grown in a convenient part of the garden, should be secured, then protection from frosts will be easy by simply nailing some laths on upright stakes one foot above the blooms, to bear canvas, scrim, or mats, as the case may be.

It is certainly not wise to plant dahlias in a poor soil, for it must be remembered that a wealth of blossom is wanted; time in which the plants are to make their growth is, indeed, short, and poor soils will not induce a moderately vigorous growth. The ground should be trenched two feet deep, a moderate quantity of well-rotted manure put in, and more, of littery nature, spread on the surface. The surface mulchings should be repeated if necessary, and stimulants may be given when required. Give the plants ample space to grow in, but do not waste it, as, of course, in respect to covering against frost, none must be wasted.

One dozen good varieties are Darkness, crimson-maroon; Fugi San, orange-yellow; Kitty, rosy-mauve; Masterpiece, dark purple, tipped white; Mikado, scarlet centre, yellow margin; Yellow Satin, pale yellow; Yellow Queen; Snowdrop, white; Princess of Wales, pink; Miss Morland, crimson-scarlet; Tennyson, dark crimson; and Columbine, clear rose.

Pompon Dahlias.

Of course, all sections may be grown for the supply of cut flowers, but I will only refer further, in these notes, to the pompons, which bear such a profusion of blooms, and which are so suitable for cutting with long stems to fill vases in contrast to the singles. The same kind of treatment will do for them, and so I will simply name a few good varieties possessing fairly distinct colours, as these show to the best advantage in the artificial light in dwelling-rooms. Bacchus, bright scarlet; George Brinckman, pure white; Cheerfulness, old gold, tipped crimson; Buttercup, golden yellow; Arthur West, deep crimson; Guiding Star, a very fine pure white; Little Prince, crimson and white; Peacemaker, snowy-white; Rosebud, white edged rosy-pink; Sunset, bright orange; Tommy Keith, red, tipped white; and Hedwig, chestnut and gold; the flowers of this variety look charming mixed with autumn foliage. GEO. GARNER.

THE WINTER HELIOTROPE.

This plant, whose botanical name is Tussilago fragrans, is related to the common coltsfoot (Tussilago farfara), and therefore, like all the coltsfoots, is a bad master, though a good servant. In this respect it resembles the bindweed, which, though very ornamental in the garden when in flower, has such a spreading habit that it can only be planted with safety in spots where it has no opportunity of making its way underground into choice borders or beds.

It is almost impossible to eradicate the Winter Heliotrope when once firmly established in congenial soil, and a colony has been known to be dug out twice to the depth of 2ft., which still occupies its original site, but in most gardens there are out-of-the-way corners where it may be planted without becoming a pest.

Here there is a deep depression in a corner between a wall and a high bank, which has apparently been for generations the receptable of all manner of rubbish, broken crockery, bottles, slates, tiles, and such-like, to a depth of several feet. Over this about a foot of soil was spread, and some roots of winter heliotrope begged from a neighbour, who was only too glad to get rid of it. Now, in the depth of winter a couple of dozen or so sweetly-scented flower-heads may be picked, which with the handsome heart-shaped leaves form an attractive and perfumed decoration in the house. A dry bank, where little else will grow may be profitably devoted to this plant.

It is said to be a native of Italy, but has, even if not a native of this country, become thoroughly naturalised here. Its flowers differ from those of the common coltsfoot in being borne in dense clusters of many flower-heads ranging in colour from lavender-white to purple, whereas the yellow blooms of Tussilago farfara are borne singly, and are daisylike in form. The blossoms have a delicate nutty or vanilla-like perfume, and are borne at a time when few other flowers, except those of the Algerian irises and Christmas roses, are available for indoor decoration from the open garden.

WYNDHAM FITZHERBERT.

Salvias.—The brilliantly-coloured Salvias splendens grandiflora and Pride of Zurich may now be placed out of doors. The flower spikes must be pinched out, and they should receive their final potting. During the summer months the pots should be plunged in ashes. This will save much labour, as they will not need so much attention in regard to watering. If red spider attacks the leaves, dip them in an insecticide, or lay them on their sides and syringe them, but syringing with clear water morning and evening will do much to keep them clear from this pest.—E. HARRISS.

COLCHESTER ROSE AND HORTICULTURAL SOCIETY.

SUMMER EXHIBITION,
WEDNESDAY, JULY 2nd, 1913.
CHALLENGE CUPS for both EXHIBITION and DECORATIVE ROSES.
Schedules from the HON. SECRETARY,
POWNALL CRESCENT,
COLCHESTER.

HANLEY PARK, STAFFORDSHIRE
JULY 2nd and 3rd, 1913.

SEVENTEENTH
GREAT ANNUAL FLORAL FETE.
£300 in Prizes, Silver Cups, Gold and Silver Medals.
SILVER CHALLENGE CUP, VALUE £10 10s. 0d., OFFERED FOR "TRADE EXHIBIT."
(For particulars see page 7 in Schedule.)
Valuable Special Prizes offered by the Principal Firms in England.
Schedules post free on application to
WM. POULSON,
Secretary.
Town Hall, Hanley.

ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER AND THE NORTHERN COUNTIES.
MANCHESTER ROSE, SUMMER SHOW, AND HORTICULTURAL TRADES EXHIBITION,
at the EXHIBITION BUILDINGS, RUSHOLME, MANCHESTER.
JULY 11th and 12th, 1913.
ROSES, SWEET PEAS, GROUPS, STOVE and GREENHOUSE PLANTS, CARNATIONS, BEGONIAS, Etc. A Good Prize List.
Schedules and all particulars from—P. WEATHERS, Sec., Botanical Gardens, Manchester.

HORTICULTURAL SHOW ADVERTISEMENTS are inserted in this column at Sixpence per line, the minimum charge being Two Shillings and Sixpence. Offices, 148 and 149, Aldersgate Street, London, E.C.

EXHIBITIONS AND MEETINGS.

Royal Horticultural Society.

Although coming so close after the great Chelsea Show, the meeting held at the Royal Horticultural Hall on June 3 was a good one, and the show of first-class order. Every bit of available space was filled, and, taken as a whole, the groups were well arranged and the plants and flowers in excellent condition. In a few cases the error of overcrowding was observable. Orchids, carnations, roses, pelargoniums, fuchsias, alpine and border flowers, and sweet peas and antirrhinums were the principal features. The attendance was not very large owing to the large number of society functions that were being held in town the same day.

ORCHID COMMITTEE.

A beautiful exhibit of orchids, admirably staged over maidenhair ferns, by Mr. Geo. E. Day, gardener to H. S. Goodson, Esq., Fairlawn, West Hill, Putney, proved a great attraction, and, indeed, it was a fine effort from a private collection within the metropolitan area. Odontoglossums were especially numerous, and included such good things as O. Snowflake, O. crispum Battle of Waterloo, O. c. Fredericki, O. amabile roseum, O. Lambeauianum, O. St. Luce, and O. Goodsonæ. Cattleya Mossiæ, C. M. Reineckiana, C. Dusseldorfi var. Undine, Lælio-cattleya Canhamiana, L.-c. Lady Wigan, Cymbidium Lowianum, miltonias, and some odontiodas were other subjects well represented. Messrs. Hartland and Sons, Cork, contributed a few orchids, and also showed Diananthe cœrulea, a curious Chinese hardy alpine plant.

Oncidium serratum was well shown by Messrs. Hassall and Co., Southgate, together with Miltonia vexillaria Cobbiana carrying two spikes, some bright odontiodas, and good forms of Cattleya Mossiæ. Conspicuous in the exhibit from Messrs. Stuart Low and Co., Enfield, were Renanthera Imschootiana, Miltonia Hyeana with three spikes, Cattleya Mossiæ Reineckiana, L.-c. Eudora, and the beautiful mauve Brasso-Cattleya Veitchi.

From Sir Trevor Lawrence's collection at Burford Lodge, Dorking, Mr. White brought Lælio-cattleya Canhamiana Burford var., with broad white sepals and petals; the graceful white and purple Odontoglossum Lairessei (A.M.), the quaint little Epidendrum organense, a lowly plant with greenish flowers; and a fine example of Oncidium Cleaesianum with brown and purple flowers. Two interesting hybrids came from Mons. H. Graire, St. Fuscien, Sains; these were Odontoglossum Saturne and O. Neptune var. St. Fuscien, the latter a bright red-blotched hybrid between O. nebulosum and O. crispum (A.M.).

Lælio-cattleya The Freak, shown by Mr. Duncan, gardener to C. J. Lucas, Esq., Warnham Court, Horsham, was a source of great interest, as its parents were L. purpurata and C. citrina; it has creamy sepals and petals, and a purplish lip, and the fragrance of C. citrina (Certificate of Appreciation). Mr. J. Stevenson, gardener to E. G. Mocatta, Esq., Woburn Place, Addlestone, sent up a good plant of the bright Odontoglossum Jasper, and Sir Jeremiah Colman (gardener, Mr. J. Collier), Gatton Park, Reigate, exhibited the interesting Catasetum Cliftoni and C. Colmanæ. Dendrobium Thorntoni, Veitch's var., with clear yellow flowers, occupied a central position in a group set up by Messrs. J. Cypher and Sons, Cheltenham; Miltonia Bleuana, Oncidium pulchellum, and Thunia Veitchi were other good things.

Mr. E. H. Davidson, Orchid Dene, Twyford, exhibited a few good orchids, but his Odontoglossum Aireworth Orchid Dene var., red-brown with purple margins and white-tipped lip, was the finest feature, and it secured an A.M. Cattleya Mossiæ Golden Ray, from the same grower, had yellow colouring towards the apex of each petal—an attempt at peloria. Messrs. Charlesworth and Co., Haywards Heath, had a small display of orchids, but had grand plants of Miltonia vexillaria Empress Augusta Victoria, Odontioda Bradshawiæ, Odontoglossum Dora, and Lælio-cattleya Fascinator.

Two grand spikes of Cœlogyne pandurata, its green and black flowers always attractive, were contributed by Messrs. Armstrong and Brown, Hayward's Heath, and with these were Odontoglossum Leonides magnificum with yellow and brown flowers, a fine spike of Cymbidium Lowianum concolor, Odontioda Vuylstekeæ, O. Rosefieldense, and some good examples of Lælio-cattleya Canhamiana. Lælio-cattleya Canhamiana and L.-c. C. Walter Gott were beautifully shown by Messrs. Sander and Sons, St. Albans, and these were associated with miltonias in variety, odontoglossums, odontiodas, the brilliant Renanthera Imschootiana, some beautiful varieties of Lælio-cattleya Fascinator, and Brassia verrucosa with nine spikes.

FLORAL COMMITTEE.

The beautiful sweet peas exhibited by Messrs. Dobbie and Co., Edinburgh, proved very attractive, especially the varieties Inspector, Melba, Thomas Stevenson, and Lavender George Herbert. Equally beautiful and attractive were the antirrhinums from the same firm, and the sheaves of lovely spikes of Cottage Maid, Amber Queen, Queen of the North, white; Maize Queen, Dobbie's White Beauty, purest white; Brilliant, deep rose; and Moonlight, apricot-yellow and pink, were all very charming. Phloxes from Messrs. Gunn and Sons, Olton, were capital for such an early date, and of Elizabeth Campbell and Selma there were grand spikes. Messrs. W. and J. Brown, Stamford, exhibited the crimson hybrid Dianthus Atkinsoni, and some good forms of Heuchera sanguinea. Irises of the germanica type were largely shown by Mr. C. W. Chantler, Cockmannings Nurseries, St. Mary Cray, but many of the blooms suffered from the heat.

Irises and lupins were the chief features of the display from Messrs. Barr and Sons, Covent Garden. The former were particularly good, especially the spikes of Ophir, Nellie, Moerheimi, Enchantress, the deep Taplow Purple, Eastern Queen, and the dainty Rosy Gem. Messrs. W. Artindale and Son, Sheffield, presented fine bunches of Mdme. Munier, Yvonne Cayeux, White Aster, and other pyrethrums, with Oriental poppies, lupins, and Incarvillea Delavayi, but their flowers were crowded together.

Oriental poppies made a rare blaze of colour as shown by Mr. Amos Perry, Enfield, and some of the best varieties were Marie Studholme, salmon-pink; Crimped Beauty, salmon-orange; Menelik, deep scarlet; Perry's White, and Perry's Unique (A.M.), vivid scarlet, with black blotches and deeply laciniate segments. Messrs. G. and A. Clark, Dover, rather spoiled their exhibit by crowding the flowers; Pentstemon heterophyllus, Iris sibirica Snow Queen, Verbascum Ivanhoe, and Geum Mrs. Bradshaw were a few of the more important subjects shown.

Messrs. Kelway and Son, Langport, presented a glorious selection of both single and double pyrethrums, and some lovely lupins and pæonies, but their new yellow Pæony named L'Esperance, a hybrid between P. lutea and a P. Moutan variety, was the great attraction. This was very like P. La Lorraine in its colouring, but had only three rows of petals, whereas La Lorraine is quite double. In L'Esperance the yellow shade is, perhaps, a trifle brighter, and the crimson petal bases are, of course, more prominent, while the crimson, yellow-tipped stamens form a fine centre (A.M.). At so late a date it was a surprise to find Messrs. R. H. Bath, Wisbech, showing some capital tulips, all Darwin varieties, the flowers of fine colour, form, and substance. The same firm contributed a score of bunches of sweet peas, and among these the delicate pink Lancashire was very pretty.

Messrs. Sutton and Sons, Reading, arranged a long stretch of their improved aquilegias. The flowers were displayed in colour blocks; the pink shades contrasted well with the blues, which adjoined the crimson and gold type. These long-spurred columbines are exceedingly graceful, and showed a marked improvement on the old type.

M. Drummond, Esq., Cadland, Southampton (gardener, Mr. Lewis Smith), showed a goodly batch of excellent long-spurred aquilegias.

Mr. James Box, Hayward's Heath, Sussex, had the most attractively arranged hardy flower exhibit in the hall. Besides a great variety of irises, pyrethrums, and aquilegias there were the more uncommon Anemone sulphurea, Thermopsis montana, and Pæonia alba grandiflora, in which the golden stamens contrast charmingly with the pure white petals. H. J. Talbot, Esq., Little Gaddesden House, Berkhamsted (gardener, Mr. E. Pinnook), showed the exceedingly vigorous pink-flowered stock named Nice Beauty.

Messrs. Whitelegg and Page, Chislehurst, by placing them next to the type, illustrated the greater value of such improved varieties of Heuchera sanguinea as Queen of Roses, Prince of Wales, and sanguinea superba. Lupins and Habranthus pratense were also well shown. Mesrs. Bakers, Wolverhampton, staged lupins, Oriental poppies, good batches of Primula Bulleyana, P. Lissadell hybrid, and other border flowers.

Messrs. T. S. Ware, Lim., Feltham, included several vases of excellent antirrhinums in their exhibit of hardy border and rock garden plants. Amongst the last-named we noted Linaria pallida and Geranium cinerium album as being especially good. Messrs. Wm. Fells and Son, Hitchin, made a speciality of herbaceous pyrethrums and hardy primula species. One end of the tabling contained a few very desirable alpines.

Messrs. R. Wallace and Co., Colchester, showed a large quantity of German irises. Pentstemon Wahersis is a very useful blue-flowered herbaceous plant, and the erect inflorescences were displayed to advantage. Other uncommon subjects exhibited were Calochortus Lyoni, Nectaroscordum siculum, and Allium albo-pilosum. Mr. G. Reuthe, Keston, Kent, included several desirable half-hardy rhododendrons in his display of shrubs and herbaceous plants. Amongst the former the sprays of Embothrium coccinea provided brilliant colouring.

Messrs. G. Bunyard and Co., Maidstone, gave the place of honour to a group of very

fine irises. Besides many varieties of the German iris there were vases of the moisture-loving I. sibirica sanguinea. Oriental poppies and herbaceous pyrethrums were also shown in quantity. Mr. Maurice Prichard, Christchurch, Hampshire, specialised the beautiful blue-flowered Wahlenbergia vincæfolia, which received an Award of Merit last year. Other plants of more than average interest were Primula Bulleyana, Onosma taurica, and Dianthus Beauté Lyonnaise.

Mr. Clarence Elliott, Stevenage, arranged a pleasing little rockery at the end of one of the tables, and planted broad breadths of such plants as Myosotis rupicola, Campanula Steveni, and Oxalis enneaphylla rosea. The Misses Hopkins, The Mere Gardens, Shepperton-on-Thames, built a rockery, and embellished it with appropriate plants. Messrs. Thompson and Charman, Adelphi, London, filled a table in the annexe with alpines and herbaceous plants attractively arranged in cork-faced boxes.

Mr. J. D. Webster, Chichester, showed many good Spanish irises, Richardia Pentlandi, Gladiolus Blushing Bride, and a collection of carnation blooms. Messrs. S. Bide and Sons, Farnham, Surrey, showed vases of such fragrant sweet peas as Melba, Bertha Massey, Clara Curtis, Thomas Stevenson, and Queen of Norway.

Messrs. H. Cannell and Sons, Swanley, filled a corner of the hall with polyantha roses in pots. The tall plants of such varieties as Carmine Pillar, Minnehaha, Lady Godiva, were set off by an outer row of dwarf examples of Flower of Fairfield, Maman Lavavasseur, and Jessie. Messrs. H. Cannell and Sons, Swanley, also well filled a table in an annexe with splendid plants of bronzy cannas, and trusses of zonal and fancy pelargoniums.

Messrs. H. B. May and Sons, Upper Edmonton, contributed a selection of their well-known stove and greenhouse ferns. Although this exhibit was not comparable in point of size with that at Chelsea, the standard of quality was quite as high. Messrs. Carter Page and Co., London Wall, London, contributed a selection of zonal pelargonium trusses, and cactus and pæony-flowered dahlias.

Mr. A. H. Gwillim, Sidcup, Kent, showed many pot plants of especially good gloxinias and double-flowered tuberous begonias, as well as cut flowers of aquilegias and other border plants.

A large and effective group of roses was arranged opposite the entrance by Messrs. B. R. Cant and Sons, Colchester. The plants were large ones in pots, and finely flowered, and the leading varieties were Hiawatha, White Dorothy, Excelsa, Blush Rambler, a grand mass of lovely blossoms; Dorothy Perkins, Sweet Pea, a new white rambler, and the attractive American Pillar, with large, single, carmine blooms. Some interesting roses from Messrs. Paul and Son, Cheshunt, included R. sericea pteracantha with big crimson spines; R. spinosissima, R. rubrifolia, and the double yellow R. lutea.

Messrs. G. and W. H. Burch, Peterborough, showed excellent cut roses, chiefly arranged in exhibition boxes. Mrs. Foley Hobbs, Duchess of Normandy, Claudius, British Queen, and Mrs. H. H. Welch, are the names of a few of the varieties shown.

Malmaison carnations were freely exhibited with perpetual varieties by Messrs. Stuart Low and Co., Enfield, and of the former there were good specimens of Lady Coventry, Calypso, Princess of Wales, the favourite Old Blush, Cleopatra, Baldwin, and the dark crimson Maggie Hodgson. A small, bright display of carnations from Mr. Chas. Blick, Hayes, contained good flowers of Elizabeth Shiffner, John Ruskin, Solfaterre, King George, and other fine varieties.

Mr. H. Burnett, Guernsey, again showed many excellent cut carnation blooms, which were characterised by large size, good form, and distinct colourings. Messrs. Wm. Cutbush and Son, Highgate, flanked a small collection of liliums and hardy cypripediums with large quantities of excellent cut carnations and polyantha roses in pots. The latter included the bright-flowered Erna Teschendorff.

Ten pairs of rafter-trained fuchsias were set up over one of the gangways by Messrs. Jas. Veitch and Sons, Chelsea, and in this way the pendant flowers were seen to advantage. Under these were compact nemesias in selected colours, Blue Gem being one of the best. Spanish irises, the deep blue Exacum macranthum, and a fine strain of gloxinias were other contributions from this firm. In another part of the hall the Messrs. Veitch arranged a number of very floriferous standard fuchsias over a groundwork of Calceolaria Clibrani and pteris ferns. At the entrance of the hall a small batch of canna J. B. Van der Schoot well illustrated the decorative value of this excellent yellow variety. Adjoining the fuchsias there were groups of improved anchusas fronted by such interesting primulas as P. Excelsior, P. Cockburniana, P. Littoniana, P. capitatum, and P. pulverulenta Mrs. R. V. Berkeley.

Mr. W. J. Godfrey, Exmouth, showed some pink, grey, and mahogany-shaded Oriental poppies, some old-fashioned scented-leaved pelargoniums, and some good show pelargoniums, notably Beauty of Exmouth, Black Prince, Ettie, Sandringham, and Constance. A towering, semi-circular group of schizanthus, which was contributed by A. G. Waley, Esq., Stone House, Reigate, Surrey (gardener, Mr. M. A. Dobson), was composed of splendidly grown plants. Messrs. John Peed and Son, West Norwood, displayed a praiseworthy strain of erect-flowered gloxinias.

Messrs. Thomas Rochford and Sons, Turnford Hall, Broxbourne, staged decorative specimens of the silvery-tipped Araucaria excelsa Silver Star, a variety which received an Award of Merit in 1909.

Rhododendrons, Japanese maples, Fabiana imbricata, Solanum crispum, and Olearia Gunniana were a few of the more prominent shrubs staged by Messrs. J. Cheal and Sons, Crawley. Lupins, irises, verbascums, Thalictrum dipterocarpum, and pink spiræas were all well shown by Messrs. G. Jackman and Son, Woking. The lovely and fragrant Wistaria brachybotrys alba was delightfully shown by Messrs. J. Piper and Sons, Barnes, the bushes smothered with long racemes of white flowers. W. multijuga was also exhibited, and there were Japanese maples under the wistarias. In the latter firm's exhibit of alpines, etc., Dianthus E. T. Anderton, D. Napoleon III., D. Salmonea, Wahlenbergia vincæfolia, a graceful bellflower, and Primula Bulleyana were the most conspicuous plants.

Mr. E. Beckett, V.M.H., gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, exhibited some Chinese shrubs; these were Viburnum Lupehense, with loose, flattish clusters of fragrant, white flowers; Salix magnifica, with leaves four to six inches long, and from two to four inches wide, probably the largest-leaved willow known; and Ribes longiracemosum, with pendulous racemes, twelve to eighteen inches long, carrying red-brown and green flowers.

AWARDS.

No First Class Certificate was awarded on this occasion.

Award of Merit. — To Papaver Perry's Unique, from Mr. Amos Perry, Enfield; to Stachys corsica, from Messrs. R. Wallace and Co., Colchester; to Pæonia L'Esperance, from Messrs. Kelway and Son, Langport; to Primula Excelsior, from Messrs. James Veitch and Sons, Chelsea; to Salix magnifica, from the Hon. Vicary Gibbs (gardener, Mr. E. Beckett, V.M.H.), Aldenham House, Elstree; to Potentilla Boule de Feu, from Mr. A. Hemsley, Crawley; to Iris gracillipes, from the Wargrave Hardy Plant Farm, The Arcade, Liverpool Street, E.C.; to Delphinium Mrs. F. Brewster, from Mr. R. C. Notcutt, Woodbridge; to Odontoglossum Aireworth Orchid Dene var., from Mr. E. H. Davidson, Twyford; to Odontoglossum Neptune St. Fuscien, from Mons. H. Graire, St. Fuscien, Sains, France; to Odontoglossum Lairessei, from Sir Trevor Lawrence, Bart., Burford Lodge, Dorking.

Certificate of Appreciation.—To Lælio-cattleya The Freak (L. purpurata × C. citrina), from C. J. Lucas, Esq. (gardener, Mr. Duncan), Warnham Court, Horsham.

MEDALS.

Gold.—To H. S. Goodson, Esq. (gardener, Mr. G. E. Day), Fairlawn, Putney, for orchids.

Silver-gilt Flora.—To Messrs. Dobbie and Co., Edinburgh, for sweet peas and azaleas; to Messrs. Jas. Veitch and Sons, Chelsea, for fuchsias, gloxinias, etc.

Silver-gilt Banksian.—To Messrs. H. Cannell and Sons, Swanley, for cannas and pelargoniums.

Silver Flora.—To Messrs. G. Bunyard and Co., Maidstone, for hardy flowers; to Mr. H. Burnett, Guernsey, for carnations; to Messrs. B. R. Cant and Sons, Colchester, for roses; to Messrs. J. Kelway and Son, Langport, Somerset, for pæonies and pyrethrums; to A. G. Waley, Esq., Reigate, for schizanthuses; to Mr. Webster, Chichester, for carnations; to Messrs. Sander and Sons, St. Albans, for orchids; and to Messrs. Armstrong and Brown, Tunbridge Wells, for orchids.

Silver Banksian.—To Messrs. R. H. Bath, Lim., Wisbech, for tulips and sweet peas; to Mr. Jas. Box, Lindfield, for hardy flowers; to Messrs. G. and W. H. Burch, Peterborough, for roses; to Messrs. G. and A. Clark, Dover, for hardy flowers; to Messrs. Wm. Cutbush and Son, Highgate, for roses, etc.; to Messrs. Gunn and Sons, Olton, for phloxes; to Messrs. Stuart Low and Co., Enfield, for carnations; to Messrs. H. B. May and Sons, Edmonton, for ferns; to Mr. Amos Perry, Enfield, for poppies, etc.; to Mr. G. Reuthe, Keston, for hardy plants; to Mr. L. R. Russell, Richmond, for ivies, etc.; to Messrs. R. Wallace and Co., Colchester, for hardy plants; to Mr. C. Blick, Hayes, for carnations; to Messrs. J. Cypher and Sons, Cheltenham, for orchids; to Messrs. Stuart Low and Co., Enfield, for orchids; to Mr. E. H. Davidson, Orchid Dene, Twyford, for orchids; to Messrs. Charlesworth and Co., Hayward's Heath, for orchids; to Messrs. Hassall and Co., Southgate, for orchids; and to Messrs. James Carter and Co., Raynes Park, for collection of lettuces.

Bronze Flora.—To Messrs. Barr and Sons, Covent Garden, for irises and lupins; to Mr. W. J. Godfrey, Exmouth, for pelargoniums, etc.; to Mr. L. Gwillim, for gloxinias; to Messrs. J. Piper and Sons, Barnes, for wistarias; to Mr. Maurice Prichard, Christchurch, for hardy flowers; to Messrs. T. S. Ware, Lim., Feltham, for hardy flowers; and to M. Drummond, Esq., Southampton, for aquilegias.

Bronze Banksian.—To Messrs. W. B. Hartland and Co., Cork, for orchids.

Kew Guild.

The Kew Guild annual meeting and dinner was held at the Holborn Restaurant during the evening of Wednesday, May 21. The Royal Horticultural Society's Spring Show always brings many old Kewites to London, and those who are home from the Colonies and other countries far away generally find their way to the same exhibition, hence this annual gathering is well attended. Mr. A. C. Hill, the assistant director at Kew, who is also chairman of the Guild Committee, presided over the annual meeting. New rules were submitted and adopted with minor amendments. These chiefly refer to the retirement of a third of the committee annually, the retiring members not being eligible for immediate re-election; to the investment annually of two-thirds of the life subscriptions received; to the holding of the annual meeting and dinner in London towards the end of May; and to the proposed institution of a benevolent fund for the help of distressed members.

Mr. Wm. Goldring, the President for the ensuing year, presided at the dinner, at which there were nearly a hundred present, including Mr. E. Brown from Uganda, and Mr. MacMillan from Ceylon, members of the Kew staff, and Kewites from all parts of the United Kingdom.

The Chairman proposed "Prosperity to the Kew Guild" after the usual loyal toasts, and he spoke very highly of the fine work accomplished at home and abroad by Kew men whom he had met with in his journeyings. He urged the young men at Kew and all Kewites residing in and around London, to make the most of the opportunities Kew affords for study; he added that, whatever success he had achieved as a landscape gardener was due to his long and close association with Kew, and the varied scenes and wide range of cultivated plants Kew contained. Mr. E. Brown and Mr. MacMillan responded, and each paid tribute to the influence of Kew and the skill of Kewites abroad. Mr. Brown pointed out that there was room for considerable improvement in the Colonies, because very often a college-trained man was given a position that a practical man, such as one trained at Kew, should and could properly fill.

An excellent musical programme was provided, and a quarter of an hour's interval gave old friends an opportunity of a handshake and a chat. "The President" was proposed by Mr. Chas. H. Curtis, who referred to Mr. Goldring's work at home, in India, and in America, and to the honour the Guild received from the success of any one of its members. Musical honours were accorded, and the President suitably replied. "Auld Lang Syne" brought the proceedings to a close at a fairly early hour.

The Perpetual Carnation Society.

The date fixed for the annual dinner of the Perpetual Carnation Society — Wednesday, May 21—was, to be paradoxical, well chosen, but unfortunate. It was well chosen, because probably a larger number of the members and friends of the society were in town that evening than would have been possible to get together on any other date, but it was unfortunate that the Kew Guild dinner, also held at the Holborn Restaurant on the same evening, had prior claim to the attendance of a good many who would otherwise have readily enjoyed and added to the enjoyment of the excellent dinner and delightful entertainment over which Mr. J. S. Brunton ably presided. It must not be supposed that the clashing caused anything approaching unhappy results, for a company of fifty-six persons sat down at the well-spread and beautifully decorated tables, every one of whim evidently throughly enjoyed the whole proceedings. Among the company present were a number of ladies, and several visitors from a distance, a few coming even from France.

The loyal toasts were proposed by the Chairman, who also responded to that of "The Perpetual-flowering Carnation Society," which Mr. D. Ingamells proposed in a brief but well-chosen speech. Mr. Brunton, in the course of his reply, remarked that the society is making steady progress, its membership now numbering nearly 500, and extending to almost every country in Europe, as well as to South Africa.

To Mr. C. Engelmann fell the privilege of proposing the health of the chairman, which he did in eloquent and entertaining language, the whole company approving in no uncertain manner.

Broughty Ferry Horticultural Association.

The ordinary monthly meeting was held under the presidency of Mr. James Bethel in the Y.M.C.A. Hall on the 20th inst. The lecturer for the evening was Mr. James Robertson, head gardener, Letham Grange, Arbroath, who had for his subject "The Cultivation of Stone Fruits." Taking apricots, cherries, nectarines, peaches, and plums, the lecturer proceeded to describe the best methods of cultivating them in their best varieties in the open as wall trees, and in the case of cherries and plums as standards and bushes. He afterwards dealt with them as indoor subjects in permanent houses and improvised orchard houses, where they were usually grown in pots and tubs. He pointed out the necessity in all cases of having lime in the soil, and the feeding of the trees with phosphates, nitrates, and potash. With reference to training, the lecturer generally condemned the free growing system usually recognised as fan-trained or bushes as pot trees, his idea being that better results were obtained from cordons in each case. Stating the case for peaches and nectarines in a permanent border, the odds were against the fan-trained tree occupying so much space with the fruits all ripe within a few days, and then, when it was desired to plant a new tree the old one had to be cleared out. A prolonged discussion ensued, and on the call of the president the lecturer was cordially thanked. The monthly award was made to Mr. D. K. Meston, The Lodge Gardens, for a well-flowered Anthurium Scherzerianum Wardi.

Royal Scottish Arboricultural Society.

The first excursion for the season of the members of the Aberdeen branch of this society took place recently, when Drum Castle and woods, some seven or eight miles from Aberdeen, were visited. The day was beautifully fine, and the whole valley of the Dee was bathed in sunshine.

Drum Castle is the home of Mr. A. F. Irvine, the present chairman of the branch, and that gentleman met the members at Drum Station, and accompanied them in their tour. The party was the largest the branch had ever had at an excursion, and included Sir John Gladstone, of Fasque; Sir John Fleming, of Dalmuinzie; Mr. Sydney J. Gammell, of Drumtochty; Mr. M. V. Hay, of Scaton; Mr. A. M. Ogston, of Ardoe, and many other landed proprietors, factors, and foresters for forty miles round. Apologies were received from Sir Thomas Burnett, Bart., of Leys; Sir John Macpherson-Grant, of Ballindalloch; Mr. Nicol, of Ballogie, and many other leading gentlemen and foresters.

When all were marshalled, each with his sprig of Scots pine denoting membership of the society, Mr. Irvine led the way to a very fine wood of Scots pine about 50 years of age. Here the skill and management brought to bear on the wood were much admired. From thence the party proceeded to a wood of similar trees, planted from 80 to 100 years ago. Here some grand old specimens were found, and the foresters held some animated conversations over what they saw. Younger woods, varying from 12 to 36 years old, were then inspected, when an adjournment was made to the Castle, where luncheon was served. Here Mr. Irvine welcomed his guests, and expressed the great pleasure it gave him to see such a large gathering.

Luncheon over, the foresters proceeded to inspect the gardens adjoining the Castle, where some magnificent trees were seen, including oak, Spanish chestnut, ash, and elm —all of large size. The most remarkable trees seen during this part of the tour were two holly trees, one on each side of the Castle entrance, which are supposed to be the largest in this or any other country.

The party then proceeded to visit the old Forest of Drum. William de Irvine, first of his line to hold the lands of Drum, received them as a reward for his services from Robert the Bruce in 1323, and during the 590 years which have passed since William entered into possession, the old forest of Drum has remained, practically speaking, in its primeval and virginal state. The privilege of inspecting this wonderful link with other days was greatly appreciated by the visitors. Extending to some 400 acres, many capital specimens were seen of gnarled oaks, old Scots pine, etc., all naturally grown. The visitors were delighted with their experiences in the fine old wood. The Castle was then visited, and the famous old tower—erected generations before the Irvines came into possession—proved an object of great interest.

A meeting of the branch was then held, Mr. Irvine presiding. Since their last meeting, the Chairman said, the branch had lost a very prominent and highly-respected member in the death of Mr. A. M. Gordon, of Newton, the first president of the branch, and who gave it its first send-off. He moved that they record in their transactions the deep sense of the loss sustained by the death of Mr. Gordon, and that an excerpt of the minutes be sent to Mrs. Gordon and family. This was unanimously agreed to. Mr. R. J. Nicol, younger, of Ballogie, was admitted a member of the branch. The Secretary intimated that, through the kindness of the Seafield trustees, the branch would make an excursion to the famous Cullen woods on August 9.

Mr. Gammell, of Drumtochty, proposed a vote of thanks to Mr. Irvine for the great kindness and hospitality he had shown them that day. Needless to say, the response was hearty in the extreme, and cheers were cordially given for the president and Mrs. Irvine. The party then wended their way to the station, all delighted with the experiences they had undergone.

Reading Gardeners' Association.

Fortune favoured the members of this society on Wednesday last, when, by kind permission of the Right Hon. the Earl and Countess of Carnarvon, the beautiful grounds and gardens at Highclere Castle, near Newbury, were visited.

A large muster of members assembled at the G.W.R. station and journeyed to Newbury by the 10.33 train. Newbury was reached at 11.15, outlying members having been picked up at intermediate stations. Brakes conveyed the visitors to Highclere by way of Wash Common, and an exceedingly pleasant drive was enjoyed. On reaching the outskirts of the park the party was met by the head gardener, Mr. Blake, and conducted by him round the lakes, the banks of which are clothed with a profusion of rhododendrons and azaleas in most varied colouring. A walk of a mile and a-half through lovely woodland drives brought the party to a large marquee erected on the outskirts of the park, where, by the kindness of the vice-president, an excellent luncheon was in readiness.

Here the party was joined by the President, the Vice-President, Mr. W. Pole Routh, and Mr. Arthur Sutton, who had motored over. The President proposed the loyal toast, which was heartily received, and a verse of the National Anthem was sung.

Mr. Arthur Sutton then proposed the health of the Earl and Countess of Carnarvon, requesting their representative, Mr. Blake, to convey to them the sincere thanks of the company for their kindness in permitting a visit to their lovely demesne. Mr. Blake having responded,

The Chairman proposed the health of the Vice-president, expressing the thanks of the party for his kind entertainment. This was received with applause. Mr. Leonard Sutton, in reply, expressed the pleasure it gave him to be with the members that day. In conclusion, he gave the toast of the President, thanking him for affording the members the pleasure of his company on yet another annual excursion.

Luncheon concluded, the party was driven to the gardens and then conducted by Mr. Blake through the glass houses and walled garden. A fine crop of melons in one of the houses was specially noticed. From the gardens the tour was continued past the noble mansion to the delightful lawns and pleasure grounds, where lovely beds of rhododendrons and azaleas, just at the zenith of their beauty, made a really dazzling colour effect, one bed of rhododendrons—Pink Pearl—being particularly charming. The magnificent cedars (for which Highclere is celebrated) and other giant trees also proved a great attraction to the visitors.

At 4.15 the party repaired to a large marquee on the lawn in front of the mansion, where, by the kindness of the Countess of Carnarvon, tea was served, and this kindly thought of her ladyship was very greatly appreciated. Reading was reached at 7.30 after a most enjoyable, instructive, and successful outing.

ANSWERS TO CORRESPONDENTS.

Editorial Communications should be addressed to the Editor of the GARDENERS' MAGAZINE, 148 and 149, Aldersgate Street, E.C.

Secretaries of horticultural societies are invited to send early notification of forthcoming exhibitions and meetings, and are requested to advise us concerning changes of dates.

Specimens of plants, flowers, and fruits for naming or opinion should be sent to the Editor of the GARDENERS' MAGAZINE, "Endsleigh," Priory Park, Kew, Surrey, and as early in the week as possible. All parcels must be sufficiently prepaid.

The Editor will be glad to receive photographs of gardens, plants, flowers, trees, fruits, etc., for reproduction in the GARDENERS' MAGAZINE. He will also be greatly obliged by correspondents sending early intimation of interesting local events relating to horticulture. In sending newspapers containing matter to which they wish to draw attention, correspondents are requested to distinctly mark the paragraph.

MILDEW ON CUCUMBERS.—J. T. M., Leighton Buzzard: I shall be very glad if you will tell me the cause of and cure for mildew on cucumbers. I have mildew very badly in my plants; insecticides have been used, but with no effect.—The cucumber mildew is oftentimes very destructive, and it is a difficult matter to say just how the disease obtains a footing. Some error in cultivation lays the plant open to attack; a dry atmosphere followed by very moist conditions is an error often overlooked; cucumbers should always enjoy warmth and moisture in soil and atmosphere. A low temperature and superabundant atmospheric moisture is also very weakening, and predisposes a plant to various evils. Remove the leaves that are very badly attacked and burn them, and spray the plants with a weak Bordeaux mixture, every care being taken to moisten the under and upper surfaces of every leaf.

MALFORMED CALCEOLARIA BLOOMS.—J. T. M., Leighton Buzzard: Can you tell me the cause of malformation in the calceolaria blooms enclosed? Some have a scalded appearance, others fail to open or inflate properly, while others are perfect.—Lack of shading at an early hour during the recent spell of brilliant sunshine, and possibly also a lack of ventilation at night, are responsible for the scalding of some of the flowers, while the malformation appears to be due to feeding with strong liquid manures, the latter killing many of the root hairs, the supply of moisture needed by the foliage and flowers being thereby reduced very considerably.

WINTER GREEN STUFFS.—M. C., Hadleigh: I am an amateur with a rather large garden, and rather pride myself upon the supplies of vegetables I maintain. At present we lack rain, and the winter green stuffs of all kinds are ready to move, but as yet their permanent quarters are not available. Would pricking off be a satisfactory method at such a trying period?—We hope you have had a share of the rain that fell last week, and took advantage of it to transplant your Brussels sprouts, kales, etc., about six inches apart. In the absence of rain soak the seed beds with clear water, and draw drills three inches deep in positions where transplanting can be done. Thoroughly soak the drills with water, and, as soon as the soil is workable, lift the seedlings carefully and transplant them in the drills. Follow this with a good watering to settle the soil about the roots, and then draw the loose soil up to the plants so that the moisture given may not evaporate too quickly. We are strong believers in the transplanting of seedling green stuffs once or twice before they are put in their permanent quarters.

HEN AND CHICKEN DAISY.—J. H. D., Caerphilly: I enclose a daisy picked from a local garden. Could you kindly tell me what such a growth is called? It does not appear to me to be fasciation. Any comment or explanation will be greatly appreciated.—You are right in assuming that the peculiar formation of the daisy head is not due to fasciation. The descriptive term used to characterise the production of numerous small heads of bloom around the ordinary flower-head is proliferation; the popular title of such a quaint production is Hen and Chicken daisy.

ABOBRA VIRIDIFLORA.—C. O., Aylesbury: A tuberous-rooted plant labelled Abobra viridiflora has been given me, and I shall be glad if you will tell me how it should be managed.—Abobra viridiflora is a Cucurbit, and one that should be cultivated in the same manner as a dahlia, except that it is a climber, and should have an arch or an arbour to climb over. It loves sunshine, has elegant foliage, and, under certain circumstances, bears bright scarlet fruits. There are male and female plants, and it is necessary to plant these near each other to ensure the fertilisation of the female flowers, and the consequent formation of fruits. Find out later on whether yours is a male or female plant, and then endeavour to obtain the complementary plant for another season. Lift and store the tubers as for dahlias, and propagate from cuttings in the same way, or raise from seeds if these can be obtained. Abobra viridiflora is a South American plant.

ROSA HUGONIS.—S. J., Dorcester: I have an idea you figured Rosa Hugonis some time ago, and shall be very pleased if you will kindly give me the reference to the figure, and state whether this species is of garden value as distinct from botanical interest.—Rosa Hugonis was figured in our issue of March 28, 1909, p. 243. This free-flowering species was raised at Kew from seeds collected in Western China by Father Hugh Scallan, who sent them to the British Museum, from whence they came to Kew. In habit, spines, and flower structure, R. Hugonis shows its close affinity to R. spinosissima, a British species. The flowers are light yellow, two inches across, and produced in great profusion all over the bush during the month of June. From this you will gather that R. Hugonis is a good garden plant.

NAMES OF PLANTS.

D. B., Wellingborough.—1, probably a form of Odontoglossum Hyeanum; 2, O. Lambeauianum; 3, O. ardentissimum; 4, Oncidium bracteatum.

J. T. M., Leighton Buzzard.—1, A sedum, species not recognised, send when in flower; 2, Anthericum biliago; 3, Saxifraga sarmentosa—the popular Mother of Thousands.

F. H. D., Exmouth.—The specimen sent is a leaf of Tolmiea Menziesi, an interesting member of the Order Saxifrageæ. It is specially interesting because of the frequent development of a bud, and subsequent plantlet, at the point of junction between petiole and leaf-blade.

A SCHEME FOR HORTICULTURAL EDUCATION.

In presenting the following syllabus, suggested as suitable for a course of instruction in elementary horticulture, the Horticultural Education Association desire to point out the importance of giving attention to principles, for it is upon the proper application of these that success depends. Principles hold true for all places, whereas the common mode of teaching horticulture leads to a knowledge of methods applicable only to the localities in which it has been acquired. It is believed that the best results will follow when a thorough knowledge of principles has been instilled by practical work in the classroom, and a large measure of technical skill in horticultural practice acquired in the garden.

There is no need to go into the byeways of physical, chemical, or botanical studies, and an elementary course can include only those points that have a direct bearing upon horticultural practice. Every care must be exercised by those engaged in horticultural teaching to see that the practical bearing of the various scientific studies is emphasised, and that the principles involved in the technical exercises undertaken are apprehended by the pupils.

It is unlikely that any scheme for the technical instruction of young gardeners could be adopted in its entirety for every district and class; it would need adapting to local conditions, to the special requirements of the particular class of students, to the facilities which can be made for carrying out the scheme, and to the composition of the teaching staff, but it is believed that the scheme outlined herewith may be made the basis for a course in horticulture suitable for young horticulturists, and a valuable introduction to their craft.

The scheme is dealt with under the following heads: (1) Centres; (2) Length of Courses; (3) Syllabus (A, principles; B, operations).

(1) CENTRES.—It is desirable that special horticultural courses should be provided in each county or group of counties, as is the case with agricultural courses in Farm Institutes. The Farm Institute is suggested as a possible centre, but it is regarded as essential that a special garden of not less than five acres, with fruit, vegetables, and flowers, should be established.

(2) LENGTH OF COURSES.—Short courses of, say, three months, either continuous, or from six to thirteen weeks, divided into two or more periods, should be provided first; and the most promising students should be awarded scholarships providing for longer periods of instruction in approved institutions.

(3) SYLLABUS:—

A.—Principles.

(1) Life histories of typical plants. (2) Study of organs concerned in nutrition; (a) functions of roots, absorption of water and earth salts; (b) functions of stems, movement of sap, etc.; (c) functions of leaves, photosynthesis and transpiration. (3) Influence of external conditions on plant form; various growth forms assumed by plants under varying conditions; and the natural distribution of plants. (4) Various processes of nutrition under special conditions (e.g., parasitic, symbiotic, carnivorous and saprophytic plants).

(5) Study of flowers, and processes leading to seed production. (6) Study of typical fruits, and methods of seed distribution. (7) Study of structure of seeds; germination, respiration, seed testing. (8) Vegetative methods of propagation. (9) Storage of food and uses of storage organs in propagation, etc. (10) Study of buds of trees, etc., arrangement and development. (11) Special physiology of pruning. (12) Physiology of grafting and budding. (13) Elementary classification of plants. (14) Methods of obtaining and fixing new varieties; Mendel's theory.

(15) Study of typical soils, their origin and formation. (16) Water and air in soils. (17) The life in the soil, formation of nitrates. (18) Principles of manuring. (19) Symptoms and treatment of diseases, including the study of insects and fungi.

B.—Operations.

(1) Garden planning. (2) Tillage operations—draining, digging, trenching, hoeing, etc. (3) Manuring—time and methods of application, farmyard manures, chemical manures. (4) Sowing operations—preparation of seed beds and seed sowing. (5) Vegetable culture — arrangement and cropping of kitchen garden, forcing of common crops, rotation of crops. (6) Fruit culture—hardy fruits, planting, pruning, spraying, budding and grafting; fruits under glass. (7) Cultivation of flowering and foliage plants—uses in gardens, propagation, planting.

(8) Grading, packing, storing, and marketing garden produce. (9) Cultivation of ornamental shrubs and trees—their uses, propagation, pruning, etc. (10) Plant structures—management, furnishing, heating, watering, ventilation, etc. (11) Propagation of plants by various methods. (12) Hybridisation—pollination, selection.

WALTER P. WRIGHT,
Hon. Secretary,
Horticultural Education Association.

NEW BOOKS.

CLAY'S SUCCESSFUL GARDENING.

By Professional, Amateur, and Market Growers. (Clay and Son, Stratford, E.; and Simpkin, Marshall, Hamilton, Kent, and Co., London, E.C.) Price 1s. net.

The inclusion of "successful" in the three words which form the title of this excellent handbook of practical horticulture is singularly appropriate. Not only have the large body of contributors to its pages set forth with remarkable clearness and great ability the course of procedure by which the highest degree of success can be achieved in the cultivation of the several classes of plants, flowers, fruits, and vegetables that have a place in the garden, but the book itself is one of the greatest successes in gardening literature of recent times. The edition now before us is the fifth, and the several issues have followed each other in such rapid succession that it comes somewhat of a surprise to find how short, comparatively speaking, has been the period since the first edition made its appearance on our table.

Although it may not be easy to bring about such splendid results as those obtained by Messrs. Clay and Sons in publishing their handbook, it is not difficult to understand in some degree how it is that they have succeeded so well. At the inception they were careful to include in the contents matters of the greatest importance in the economy of the garden, and having prepared the list of contents, they proceeded to obtain the co-operation of writers of the highest eminence in the several branches of practical horticulture. Hence it was that the matters dealt with appealed to all who were more or less interested in gardening, and a brisk demand quickly followed the issue from the press. In the preparation of the subsequent editions additional subjects were introduced, and the aid of other writers, also of eminence, obtained, and the previous chapters thoroughly revised by their respective authors. Consequently each edition was for all practical purposes new and thoroughly up-to-date, and therefore possessed the freshness characteristic of a quite new book.

The list of writers is somewhat formidable, and probably to no other single volume on gardening have so many horticulturists of the first class contributed. In a careful survey of the 331 pages we find Mr. George Gordon, V.M.H., dealing with the "Garden under Glass"; Mr. T. W. Sanders, F.L.S., writing on "The Gay Garden"; Mr. J. Harrison Dick on "Small Suburban Gardens"; Mr. F. W. Harvey on "Hardy Herbaceous Plants"; Mr. W. A. Cook on "Beautiful Evergreen Shrubs"; and Mr. H. Hemsley on "Rock Gardens." The writers on special classes of flowers include Mr. H. Cowley, Mr. E. H. Jenkins, Mr. Horace J. Wright, Mr. H. A. Smith, Mr. T. Stevenson, and Mr. E. F. Hawes. The principal writers on fruits and vegetables are Mr. J. Hudson, V.M.H., Mr. E. Beckett, V.M.H., and Mr. W. Iggulden. Mr. J. Wright deals with the exhibition of garden produce, Mr. C. H. Curtis with garden pests, and Mr. J. Frazer, F.L.S., with market culture.

The book contains numerous illustrations, including several examples of colour printing, and is a marvellous shilling's worth.

A POPULAR DICTIONARY OF BOTANICAL NAMES AND TERMS.

By George F. Zimmer, F.R.H.S. (George Routledge and Sons, London.) Price 2s. 6d.

This dictionary is primarily intended for the use of lovers and students of plant life in garden, field, and woodland, and, as a considerable proportion of botanical names and terms are somewhat perplexing to those who have not soae acquaintance with Latin, it should prove useful both to those engaged in the study of botany and the cultivation of plants. One of the greatest difficulties the student of botany experiences in connection with his studies has arisen from the multitudinous terms associated with botanical science, a fact that was recognised by Professor Earle many years since. "Why," he asked, "should we allow a pile of heterogeneous names stand as a barrier between our people and the fairest gate of knowledge?" He then proceeded to state that, "These strange names are all but barren of interest in themselves; what interest they possess springs wholly out of the objects they represent."

In this dictionary an endeavour has been made to render these "strange words" more interesting by giving their equivalents in the English language; and so successful has Mr. Zimmer been, that with its aid those who are interested in plants, whether cultivated or wild, will be able to readily obtain the English equivalents of the botanical terms they may meet with. The book is one that should be included in all garden libraries, and have constant reference made to it.

BEGINNER'S GUIDE TO FRUIT GROWING.

By F. A. Waugh. (Kegan, Trench, Trubner, and Co., London.)

This book has been written for the guidance of those who have had but little experience in the cultivation of the various fruits grown in American gardens and orchards. Professor Waugh is one of the leading authorities on fruits and fruit culture in America, and, as the book is remarkable for clearness of statement and is freely illustrated, it should prove most useful to those who are commencing the cultivation of fruits in Canada and the United States of America.

OF GREAT VALUE TO GARDENERS.

MANURES

FOR GARDEN AND FARM CROPS

By W. DYKE.

Edited by T. W. SANDERS, F.L.S., Editor of "AMATEUR GARDENING."

A book for which Gardeners—amateur and professional—have been waiting, and one which will fill a gap in many a garden lover's library. Mr. Dyke is an authority and treats his subject in a lucid and simple style that will without doubt convince the reader of its great importance. What he has to say on manures and fertilisers is the outcome of profound study, and long and practical experience. From this work you may learn why manures are needed, and obtain practical information in regard to the food of plants, the constituents and properties of natural and artificial manures and their application, with the object of increasing the quantity and quality of plants, flowers, and all garden and farm crops.

116 Pages. Illustrated. Paper Boards 1/- net, by post 1/2.

ORDER FORM.

To the Publishers, 148 & 149, Aldersgate Street, London, E.C.

Please send me a copy of "MANURES FOR GARDEN AND FARM CROPS," by post, for which I enclose remittance of 1/2.

OBITUARY.

MR. ALFRED AUSTIN.

It is with regret we have to record the death, on Monday, June 2, of Mr. Alfred Austin, the Poet Laureate. Mr. Austin had just passed his 78th birthday, and he died at his home, Swinford Old Manor, near Ashford, in Kent. It is not for us to deal with Mr. Austin's career as a lawyer, journalist, special correspondent, and poet, but for his wide knowledge of country and garden life, his love of horticulture, and his charming book entitled "The Garden that I Love," his memory will long be kept green by all garden lovers. This book was the most widely known, and also the most popular of the late Poet Laureate's works, and in it he discourses in a most delightful manner upon things concerning his own garden at Swinford, the garden he made, in which he lived for the greater part of 45 years, and where he passed away. Mr. Austin was intensely patriotic, and a frequent and able lecturer upon national subjects and upon country and garden life.

MARKETS.

COVENT GARDEN.

Flowers.

Tulips are over, and only a few double white narcissi remain to remind us of spring. The recent bright weather has been rather hard on flowers, such as roses, which are plentiful. Carnations and lily of the valley are in good demand, and so are irises and sweet peas.

Thunderstorm, Thursday night, May 29.

CATALOGUES RECEIVED.

JAMES STREDWICK AND SONS, SILVERHILL PARK, ST. LEONARDS.—Eight large illustrations of new dahlias adorn the pages of this new catalogue. The first twenty-three varieties described were raised by the firm, and include cactus, garden cactus, pompon cactus, and collarette kinds.

J. CHEAL AND SONS, LIM., CRAWLEY.—A concise, admirably descriptive, and illustrated catalogue of dahlias, bedding plants, chrysanthemums, and other subjects for present planting.

FORTHCOMING ENGAGEMENTS.

NEXT WEEK.

MONDAY, June 9.—United Horticultural Benefit and Provident Society.

Epsom Horticultural Society, Rose Show, June 30, at Woodcote Grove; Summer Show, August 4, at Epsom College.
Wolverhampton Floral Fete, July 8, 9, and 10, at West Park.
Ealing Horticultural Society, July 9.
Weybridge Horticultural Society, July 10, at Barham Lodge, Oatlands Drive.
Edgware Horticultural Society, July 12.
Dulwich Summer Show, July 17, at St. Barnabas Parish Hall; Chrysanthemum Show, November 12 and 13, at the Baths, Goose Green.
Ulverston Rose and Sweet Pea Show, July 18.
Birmingham Horticultural Society, July 18 and 19, in Handsworth Park.
Haywards Heath Flower Show, July 23, in Victoria Park; the twenty-fifth exhibition.
Tunbridge Wells Flower Show, July 23 and 24.
St. Quintin Horticultural Society, July 24, in the Gun Club grounds Wood Lane, W.
City of London Rose Show, July 26, at Cannon Street Hotel.
Worth Horticultural Society, July 30.

THE GARDENERS' MAGAZINE

NOTE OF THE WEEK.

The Position of Horticulture.

It is still the boast of agriculturists that they represent the most important industry in the kingdom; and, though we do not wish to dispute the point, we would put forth a plea for that cult which we and our readers are pleased to call our own. It may be well to remember that time was when agriculture predominated to the extent of monopoly, for horticulture as a commercial industry could hardly be said to exist, except in the neighbourhood of London and other large centres of population, where a few market gardens provided the supply of fruit and vegetables for the people who had no facilities for growing their own. But a change has taken place, and, while very few new farms have been created, and the methods of farming have changed without any marked progress being made, horticulture has advanced by leaps and bounds, and every year more capital and more land are devoted to it. No longer are Britain's vegetables, fruits, and flowers grown on the fringes of her big towns; for the horticulturist, assisted by cheaper and quicker transit, has pushed his way further and further into the country, and has changed the face of Nature. By way of illustrating our point, let us state a few cases. The other day we travelled through a large tract of country on the borders of Worcestershire and Gloucestershire, where every ridged and furrowed field indicated that it once grew corn. Then that order changed, for many of the fields were laid down to grass, and as many more laid themselves down, and eventually became pasture. Now a further change has taken place, and on acre after acre of this land there waves in the summer and autumn, not ripening corn, but the graceful foliage of the edible asparagus. So the gardener is supplanting the farmer, and big things have grown from small beginnings, for most of the asparagus growers were of the labouring class to begin with, and, starting in a small way on their allotments and gardens, they gradually expanded, and took in more and more of the land that once produced corn. What is very much to the point is that these growers can afford to pay more for the land than the farmer could; and a small holder who has just taken five acres of arable land to put down to "grass" pays £4 an acre, whereas no farmer who had ever held it paid half that sum. And how has the change affected this district? Apparently for the better, for building is going on, which is a good sign; and there is none of that air of stagnation so characteristic of localities devoted purely to agriculture. In fact, wherever the fruit grower or market gardener steps in, there is more money, more employment, more activity, and more independence. In the Evesham Vale, where gardening has taken the place of farming, where more is paid for the land than ever before in its history, and where more is got out of it by intensive culture, an air of thriving prosperity prevails which was unknown before the old order changed, and the spade took the place of the plough. The same kind of thing may be noticed in other places. Think of the strawberry fields in Hampshire, in the Cheddar Vale in Somerset, in Kent, and other parts that are naturally suitable for this fruit. What do we find? Even farmers are changing with the times, putting down their land to the fruit that has paid their neighbours, and, in short, are giving up, to some extent, the industry of their forebears, and becoming horticulturists. More and more of this kind of thing is being done, and in many districts farmers are cultivating vegetables because they pay; and the only man who complains is the bona-fide market gardener near to the town, who has to pay a higher rent and heavier taxes. In stating these facts, we do not wish to infer that agriculture is a dying industry, and horticulture is taking its place, but what we do contend is that Great Britain is becoming less an agricultural country and more a horticultural one. It is not unlikely that the old order will change even more with the creation of small holdings; for, whereas it is obvious that the occupier of a few acres cannot make a living by working on the lines of the farmer, he has a chance by adopting the more intensive methods of the gardener. It would be interesting to know how many acres of land that was once agricultural are now covered with glass, but the figures must be very considerable; and it would be still more interesting to discover how much more labour is employed on such land than was the case when it was in the occupation of the farmer. It would almost appear as though the farmer must go out when the gardener comes in. In view of these changes, how does commercial horticulture stand with the State? It is true we have now a horticultural branch of the Board of Agriculture, but what the new branch will do for the industry remains to be seen. Up to now, however, there has been a tendency in high places to treat horticulture as subservient to the sister craft, and for no other reason but that it has always been the case. While there are members in the House of Commons who make it their special mission to watch the interests of agriculture, can the same be said of the industry we represent? We think not; and in this respect, as well as in others, there should be a change in the order of things, for the more horticulture advances the more necessary does it become that the industry should be directly represented in Parliament.

REV. A. BRIDGE.

Rev. A. Bridge.—Among the many clergymen who take a keen interest in horticulture, and make a special hobby of some particular flower, the Rev. A. Bridge, of Worth Rectory, Three Bridges, Sussex, must be given a prominent place. Although most flowers that can be grown out of doors either all or part of the year receive his attention, it is the dahlia that appeals to him most effectively, for it has captured his affection so surely that there is no more loyal devotee of this flower than he is. Not only does he grow dahlias largely and well, but he is a keen exhibitor, who

finds pleasure in the mild excitement of a close competition at the Crystal Palace or elsewhere. The Rev. A. Bridge is a vice-president of the National Dahlia Society, and at present the only clergyman to be found among the officers of that body. Remembering how well the clergy have supported and interested themselves in the cult of the rose, it is to be hoped that the Rev. A. Bridge will not long be left in such "splendid isolation," either as a grower and exhibitor of dahlias, or as an officer of the National Dahlia Society, for he has set an excellent example to his brethren, and the cult of the dahlia is extending every day.

A Plea for Florists' Tulips.—Under date of June 1, Mr. James Bentley, of Stakehill House, Castleton, Manchester, wrote: "To-day is Tulip Sunday. There have been tulips on the dining-table at Stakehill, as there have been for the last fifty years or more, but there was nobody to look at them who understood them except myself. I look at the flowers and think of past days, when Dr. Hardy, the Rev. F. D. Horner, Samuel Barlow, Samuel Cooper, James Thurston, E. S. Dodwell, Shirley Hibberd, James Douglas, Thomas Moore, John Wood, Henry Travis, Daniel Woolley, William Kitchen, William Bentley, William Lea, Luke Ashmole, David Jackson, and scores of other men who were working on the flower, used to visit Stakehill at tulip time. These men are all dead, and to-day nobody came. Yesterday, May 31, we held the Northern Show at Middleton, and, although the price of admission was only threepence, ten people paid to see it! Poor tulip! When one thinks that for hundreds of years men have spent their lives improving the flower, bringing it to the present state of perfection (and a more magnificent flower does not grow than an English florists' tulip), and one realises that there are not thirty men in the whole world who understand its qualities, one begins to despair. Fifty or sixty years ago they were grown all over the country, and shown at more than a hundred places; now they are only grown in very few, and only shown in three places. Is our flower doomed to go out, like the English ranunculus, or will some miracle at the eleventh hour save us?"

Evolution of Plants.—The Rev. Professor G. Henslow, M.A., V.M.H., will lecture before the Royal Horticultural Society at 3 p.m. on June 17, and his subject will be "The Evolution of Plants and the Directivity of Life, as shown by Vegetative Structures."

Gardeners' Royal Benevolent Institution.—On behalf of this excellent charity the following invitation for the annual festival dinner, to be held at the Hotel Metropole on Wednesday, June 25, has been issued to the leading horticulturists of the United Kingdom by Leopold de Rothschild, Esq., who is to preside on that occasion: "Dear Sir,—I am to have the pleasure of presiding at the anniversary festival dinner in aid of the funds of the Gardeners' Royal Benevolent Institution, at the Hotel Metropole, London, on June 25, and venture to ask for the kind assistance of all lovers of flowers and gardening. Since its formation, seventy-five years ago, this national horticultural fund has distributed more than £140,000 amongst necessitous horticulturists and their widows, and is now affording permanent aid to 258 persons, at an annual cost of over £4,500. Besides, temporary assistance is given from separate funds in well-authenticated cases of urgent distress. For paying the permanent allowances there is only £950 of assured income, and consequently £3,500 has to be made up yearly. Therefore I shall feel greatly favoured if you will give me the pleasure of your company on June 25, and your generous aid towards the carrying on of this good work.—I remain, dear Sir, yours very truly, LEOPOLD DE ROTHSCHILD."

Mr. J. C. Vaughan, founder of the first American trade paper, "The American Florist," is visiting Europe this season, and expects to reach Liverpool by the ss. Victorian on June 13. It is twenty-one years since Mr. Vaughan last came over. He is a seedsman and nurseryman of high repute, with businesses in Chicago and New York. He is chairman of the National Council of Horticulture, and was closely identified with the horticultural features of the St. Louis exhibitions. Many British horticulturists will welcome this opportunity of making Mr. Vaughan's acquaintance.
